1.0. INTRODUCTION

1.1 General

The Upper Turkey Creek Flood Risk Management (FRM) project is a new project located in the City of Merriam, in Johnson County, Kansas. Efforts as part of this project include placing new levees or floodwalls, utility relocations, and replacing the Merriam and Johnson Drive bridges to increase the current line of protection. The project was designed based on updated Atlas 14 flows and hydrology provided by Johnson County, Kansas.

In accordance with the approved review plan, a facilitated Semi-Quantitative Risk Assessment (SQRA) has been conducted prior to 65-percent submittal. See Appendix I for the draft SQRA Report. The SQRA report will be updated throughout construction.

1.2 Purpose

The Design Documentation Report (DDR) provides the technical basis for the plans and specifications and serves as a design summary. The DDR covers the preconstruction engineering and design phase and the construction phase of the project. The DDR is not considered complete until after the plans, specifications, and construction are complete.

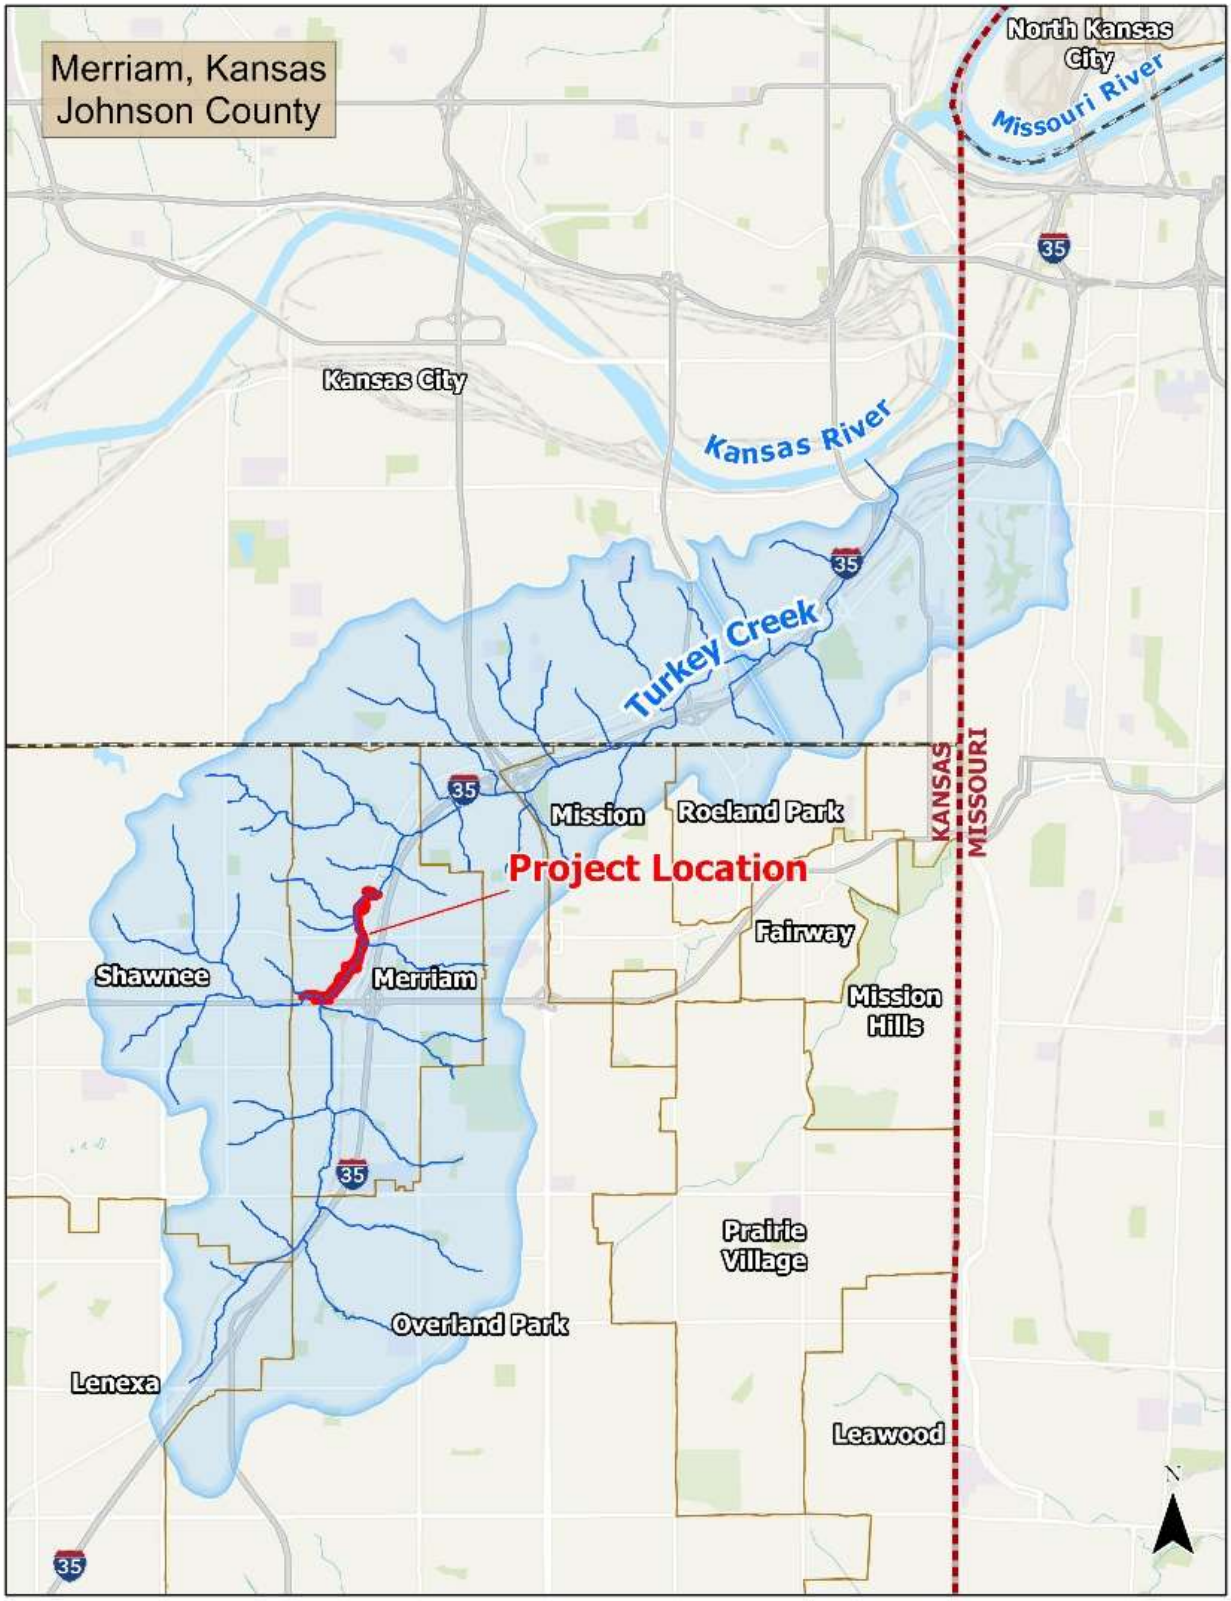
1.3 Authority

The project was originally authorized for a feasibility study by the Resolution of the Committee on Transportation and Infrastructure, U.S. House of Representatives, Docket 2616, adopted 16 February 2000. Authority for the design and construction of this project was provided in the Water Infrastructure Improvements for the Nation Act (WIIN Act) of 2016, Public Law (PL) 114-322, as recommended in the report of the Chief of Engineers dated 22 December 2015, based on the 15 March 2015 Feasibility Report with Integrated Environmental Assessment. Funding was provided in the amount of $500,000 under the fiscal year (FY) 2022 Omnibus funding-Community Project Funding/Congressionally Directed spending and in the amount of $23.9 million under the Infrastructure Investment and Jobs Act, PL 117-58.

1.4 Location

The Upper Turkey Creek FRM project is located in the City of Merriam, in Johnson County, Kansas. Turkey Creek is a right-bank tributary of the Lower Kansas River located in Johnson and Wyandotte counties, Kansas, between approximate river miles (RMs) 2.7 to 3.7. Figure 1.1 shows the location of the Upper Turkey Creek FRM project.

Figure 1.1. Upper Turkey Creek in Merriam, Kansas



1.5 Local Cooperation

The non-federal sponsor for this project is the City of Merriam, Kansas. Johnson County, Kansas, contributes to the city's cost share and is involved in the design phase. Part of the Turkey Creek channel in the study area is operated and maintained by the Merriam Drainage District (MDD) under a state charter that provides MDD authority independent of the City of Merriam or Johnson County. MDD may be responsible for operation and maintenance of this project in the future.

1.6 Historical Performance and Flood History

The Turkey Creek watershed has a history of U.S. Army Corps of Engineers (USACE) involvement. Major flood events occurred in 1951, 1958, 1961, 1968, 1977, 1983, 1986, 1993, 1995, 1996, 1998, and 2017. Although the floods of 1993 and 1998 were both extreme events, the 1998 flood appears to be the flood of record for Turkey Creek, based on high water marks.

Although the 1977 flood is locally known as the Plaza Flood on Brush Creek, significant damage occurred in the Kansas City, Kansas, neighborhood of Rosedale and elsewhere in the Turkey Creek Basin. Flood damage estimates from the September 1977 flood exceeded $8.1 million dollars and prompted the Mid-America Regional Council (MARC), a metropolitan planning organization, to request a USACE study of the Turkey Creek flood problems as a part of an ongoing Urban Study. The Urban Study determined it was not feasible to develop and implement a program for managing flood risks along Turkey Creek that would contain the 1-percent annual exceedance probability (AEP, or 100-year event) and greater flood events.

Following the 1983 flood, the cities of Kansas City, Missouri, and Kansas City, Kansas, requested additional studies on Turkey Creek flooding. In 1987, USACE produced the Reconnaissance Study of Turkey Creek. This commenced a series of studies culminating in an authorized construction project for Lower Turkey Creek in the Water Resources Development Act (WRDA) of 1999.

Flooding in and around Johnson County, Kansas, led to presidential disaster declarations in 1993 and 1998. The estimated cost of these disasters exceeded $50 million. Heavy rains on 4 October 1998, produced flooding that caused several million dollars in damage to businesses and public property along Turkey Creek in Johnson and Wyandotte counties, Kansas. Reports indicate that parts of the Kansas City metropolitan area, in both Kansas and Missouri, received almost eight inches of rain that day with some locations receiving three to five inches of rain within a three-hour period. More than five inches fell in Lenexa, Kansas, in a little more than an hour. Nearly 100 calls for water rescue were received, and numerous roads throughout the area, including individual sections of Interstate Highway 35 (I-35) and Interstate Highway 435 (I-435), were impassible.

Following the 1993 and 1998 flood losses and as Lower Turkey Creek investigations were ongoing, the U.S. House of Representatives Committee on Transportation and Infrastructure passed the 1999 resolution and adopted the Upper Turkey Creek Basin Study authority in 2000. The 1999 resolution favored a watershed perspective to future water resource development proposals. In response to the study authority, the reconnaissance phase of the study was initiated on 16 February 2000 (USACE 2001). This phase of the study found there was a federal

interest in continuing the study into the feasibility phase. The Kansas City District, along with local sponsor, the City of Merriam, Kansas, initiated the feasibility phase of the Upper Turkey Creek watershed in June 2002 to examine measures for FRM.

As of 2012, Lower Turkey Creek has an active USACE construction project. One component is the repair of an aging tunnel that diverts all flow from the Turkey Creek watershed through a bluff to the Kansas River. The channel has also been widened.

Three significant rainfall events occurred in the Turkey Creek watershed during the summer of 2017 from 26 through 27 July, 5 through 6 August, and 21 through 22 August. Storm total precipitation was highest between 21 and 22 August 2017, but the intensity was greater for 26 to 27 July 2017 and 5 to 6 August 2017. Rainfall from the events produced some of the highest stages along Turkey Creek since the flood of record on 4 October 1998. Of the events in 2017, 26 to 27 July had the highest stage and flow rate at the Johnson Drive gage, while 5 to 6 August produced the highest stage and flow rate at the Southwest Boulevard gage. The flood of 6 August 2017 likely had a peak discharge comparable to the 1977, 1983, 1986, and 1993 floods and would have caused significant damage if the constructed flood damage reduction projects had not been in place in the lower reach of Turkey Creek.

1.7 Existing System Description

The Turkey Creek watershed contains some of the most intensely developed urban locations in Johnson and Wyandotte counties, Kansas. Approximately 75 percent of the watershed consists of residential, commercial, and industrial land use. Most of Turkey Creek and its tributaries have been channelized. The need for the project lies in the potential for flooding that could result in life loss (LL) and/or property damage in the Upper Turkey Creek Basin.

1.8 Protected Area Description

The proposed protected area for this project is heavily urbanized, including downtown Merriam, Kansas, with most of the properties consisting of commercial or industrial land use. The majority of the Turkey Creek channel that passes through the City of Merriam, Kansas, can contain a 50-percent AEP (1/2-year event), although two areas flood at the 20-percent AEP (1/5-year event).

1.9 Previous Reports and/or Studies

- **Flood Protection Project, Turkey Creek, Merriam, Kansas, USACE, September 1962.** This Design Memorandum reevaluated the economic justification of a flood protection plan developed in 1946. The project was designed to alleviate flooding along Turkey Creek in Merriam, Kansas. The plan of improvement called for constructing levees along the banks, a short section of floodwall, a new channel through the entire length of the improvement area, and the modification of several bridges and roads. The report revised the recommendations for conditions, as of 1962, and provided a map of improvements and typical channel sections. This project was not constructed.
- **Letter Report for Proposed Inclusion of Turkey Creek Improvements, Modification of Local Protective Works, Kansas River, Kansas City, Kansas (Flood Control Act of 1962), USACE, Kansas City District, May 1968.** The report described the Turkey Creek flood problem and proposed a solution for addressing flood hazards. The report

Creek flood problem and proposed a solution for addressing flood hazards. The report recommended a new 28-foot-diameter tunnel to be driven adjacent to the existing tunnel, and an enlarged and deepened channel extending 11,400 feet upstream from the existing tunnel entrance. The proposed plan was never authorized or constructed.

- **Flood Plain Information Report for Turkey Creek in Metropolitan Kansas City, USACE, January 1974.** The report was authorized by Section 206 of the 1960 Flood Control Act (Public Law 86-645) as amended. The report included an evaluation of the flooding hazards associated with Turkey Creek in the metropolitan Kansas City area. The report was prepared at the request of the cities of Kansas City, Merriam, and Overland Park, Kansas, the Kansas Water Resources Board, and Kansas City, Missouri.
- **Upper Turkey Creek Basin, Johnson and Wyandotte Counties, Kansas: Section 905(b) Analysis, USACE, July 2001.** This report evaluated the potential federal interest in solutions to recurring flood damages, environmental degradation, and related water and land resource needs and opportunities in the Upper Turkey Creek Basin. A positive determination of federal interest and recommended approval by the USACE District Engineer led to development of the 2002 Project Management Plan (PMP).
- **Stormwater Management Ordinance, Chapter 7, Article 1 of City code of ordinances, City of Merriam, June 24, 2002.** This article establishes the stormwater run-off management criteria and standards for the city's secondary or major drainage system and its components (Ordinance No. 1400, §1, 3-26-01). The secondary or major system includes the primary/minor system, its overflow elements, and all Turkey Creek tributaries and drainage structures both public and private that are not identified as part of the Turkey Creek regulatory floodplain located within the City of Merriam, Kansas.
- **Northeast Johnson County Watershed Study, Johnson County, Kansas, 2005.** Johnson County Public Works conducted a watershed study of the major creeks and streams in the Northeast corner of the County. The Northeast watershed is approximately 38.5 square miles and contains 5 watersheds (Brush Creek, Dykes Branch, Lake Quivira, Rock Creek, and Turkey Creek). The project includes data collection—channels, culverts, bridges, and low opening elevations on houses and business structures in or near flood-prone areas—public meetings, and development of a plan to address future stormwater issues. The study generated new floodplain maps, identify flood prone areas and other problems (stream erosion), alternative solutions will be considered.

1.10 Design Charette

During the 35 percent design stage, USACE, the City of Merriam, Johnson County, and MDD held a design charette focused within the Merriam downtown reach of the project to explore additional alternatives besides the recommended plan from feasibility. Ultimately, it was determined the alternatives would require a significant amount of real estate acquisition and not result in significantly lower levees to deviate from the recommended plan. Appendix J contains the findings and conclusion of the design charette.

1.11 Semi-Qualitative Risk Assessment (SQRA)

A SQRA was completed after the 35 percent design stage per the approved review plan. See Appendix I – SQRA Report for more details.

2.0. PROJECT AND ASSOCIATED FEATURES

2.1. Existing Project Features

The existing Turkey Creek channel in the project area has approximately 1V:1H to 1V:2H side slopes and is mostly lined with stacked limestone blocks. The channel is generally less than 8 feet in depth. The limestone block retaining wall was built in sections from the 1960s to the 1980s and sections of it have been repaired since. The wall is maintained by the MDD. MDD inspects this area of the creek twice a year. They estimate that ten percent of the original wall has been replaced.

The limestone block retaining wall is a gravity block wall with no reinforcements tying the blocks together. The individual blocks are approximately 6 feet long, 2 feet deep, and 14 to 18 inches tall. The face of each block in the stack is offset approximately 2 inches back from the face of the block below it. There is no drain behind the wall. The wall was backfilled with local soil which appears to be mainly clay. In some recent replacement sections of wall, filter fabric and aggregate backfill were placed behind the wall.

The wall experiences regular breaches with short sections (roughly 100 feet long or less) completely collapsing into the creek (see Section 4.0 of Appendix B-5 of the Feasibility Study). The cause of the breaches is unknown, but the wall was described in the Feasibility Study as, “not an engineered structure.” When breaches occur, MDD rebuilds the section with the original limestone blocks. During site visits for the Feasibility Study, soil was observed migrating through the limestone blocks. The walls were judged to not be capable of providing support to the proposed levee or floodwall.

2.2. Proposed Project Features

The primary components of the project are earthen levee, floodwalls, bridge replacements, detention basin, and drainage structures. The overall project is approximately 1.5 miles long. A majority of the existing limestone block wall will remain, but the floodwall/levee will be set back to limit the impacts of failure of the existing wall (see Section 7.2.3). The maximum levee height is approximately 10 feet, and the floodwall height ranges from 6 to 12 feet. The levee embankment consists of compacted impervious material.

The project is broken out into two Contracts. One for Merriam and Johnson Drive bridge replacement, and a second for the levees and floodwalls construction. The bridge contract will be completed prior to the levees and floodwall contract.

2.3. Major Changes from Feasibility Study

Several items have been updated since the Feasibility Study was completed. Appendix G discusses Feasibility Study design and analyses in detail in the Preliminary DDR. This DDR discusses current criteria, design, and analysis. The following subsections discuss the major changes that have increased the scope of work for this project.

2.3.1. Bridges

There are two bridges within the project limits that must be removed and replaced that previously had either no modifications or minor modifications. Due to increased water elevations and further analysis, the existing bridges at Johnson Drive and Merriam Drive do not meet the required uplift or overturning criteria to remain. The new bridges for Merriam Drive and Johnson Drive will be Kansas Department of Transportation (KDOT) slab bridges. See Part 09– Structures for more discussion.

2.3.2. Hydraulics

Due to updates in hydraulic modeling from the Feasibility Study, and implementation of surveyed channel bathymetry, the existing conditions' hydraulic profile has changed, and an update to the design profile has been performed. Coordination between USACE and project sponsors will be required to select the adopted design profile based on the validation effort and current hydraulic analysis. Channel armoring and maintenance efforts have been an ongoing process with MDD since the Feasibility Study was completed.

Unsteady two-dimensional (2D) hydraulic modeling is being used to update the design profile in consideration of the increased level of detail and hydraulic modeling capabilities, as well as changes to the stream channel that have occurred since the completion of the Feasibility Study. Unsteady flow hydrographs computed during the Feasibility Study are being adapted and used for the current modeling effort to compare the steady flow profiles from the Feasibility Study with the unsteady flow profiles generated during this modeling update and validation effort. Appendix E presents further detail regarding the modeling validation and development.

2.3.3. Storm Drainage Structures

EM 1110-2-2902, *Conduits Pipes and Culverts Associated with Dams and Levee Systems* was updated in December 2020, after the completion of the Feasibility Study. Closure type requirements based on pipe diameter and flood rise are now prescribed in the updated EM 1110-2-2902. The closure type requirements are for new construction but are also highly recommended for retrofitting existing pipes. Table 2.1 summarizes the active closure requirements.

Table 2-1. Closure Type Requirements[1]

Flood Rise[2]	Pipe Diameter (inches)	Closure Configuration[3]
Fast	<36	One Passive
Fast	≥36	One Passive AND One Active
Slow	<36	One Passive OR One Active
Slow	≥36	One Passive AND One Active OR Two Active

[1]Table 9-1 of EM 1110-2-2902

[2]Fast flood rise refers to floods capable of rising to a flood stage with less than 12 hours prediction time. Slow flood rise refers to floods capable of rising to a flood stage with greater than 12 hours prediction time.

[3]Passive closure are typically flap gates. Active closures are typically sluice gates.

During the SQRA, the project delivery team (PDT) recommended a deviation from Table 2.1 to use one passive closure for pipes greater than or equal to 36 inches. This recommendation is based on concerns that it is not feasible for the sponsor to manually operate more than 10 sluice gates throughout the project with less than 12 hours prediction time. Note that EM 1110-2-2902, paragraph 9.4.1.3.1, states, "Active gates are used when the rate of rise of water is slow enough to allow ample time for complete operation of the gates (minimum 12-hour flood prediction time according to EM 1110-2-1913)." This contradicts Table 2.1 (EM Table 9-1PD) but agrees with the PDT's recommended deviation. See Appendix I for the Draft SQRA Report and Draft Secondary Closure Variance request.

3.0. SITE DEVELOPMENT AND SURVEY

3.1. Site Access

There are limited site access options as the proposed project is within a fully developed urban area of Merriam, Kansas, parallel to I-35 and adjacent to railroad tracks. Site access for construction and routine maintenance and operation of the project will require coordination with various stakeholders. Stakeholders include the City of Merriam, MDD, KDOT, commercial properties, and private properties. Sheet G-004 of the plan set shows contractor access during construction.

Table 3.1. Existing Merriam Drainage District Operation and Maintenance Access

Bank	Approximate Upper Turkey Creek Stationing	Details
Right	27+00	Access to creek off of West 61st Street
Right	61+74	Access to creek immediately south of Merriam Drive Bridge

See Section 10.4.1 for proposed O&M access.

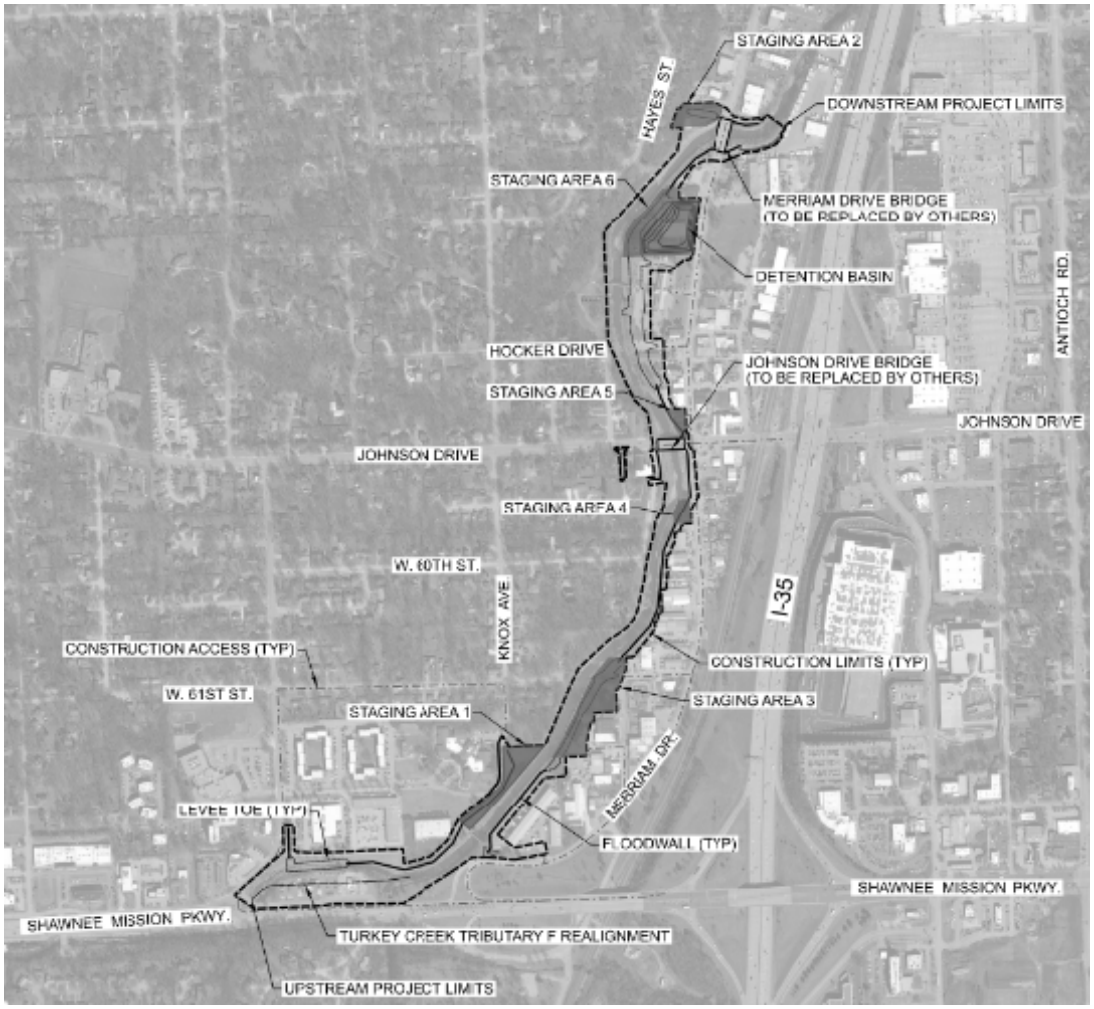
3.2. Staging Area

Table 3.2 lists proposed staging area locations. Figure 3.1 shows the staging areas of the project.

Table 3.2. Proposed Staging Areas Table

Staging Area	Bank	Details
Staging Area 1	Left Bank	South of W. 61st Street. Access via Knox Avenue
Staging Area 2	Left Bank	North of Merriam Drive Bridge. Access via Merriam Drive. Also use for Merriam Drive Bridge replacement.
Staging Area 3	Right Bank	North of West 61st Street. Access via Merriam Lane.
Staging Area 4	Right Bank	South of Johnson Drive. Access via Merriam Drive.
Staging Area 5	Right Bank	North of Johnson Drive. Access via Merriam Drive Also use for Johnson Drive Bridge replacement.
Staging Area 6	Right Bank	Detention Basin Area. Access via Merriam Drive.

Figure 3.1. Proposed Staging Areas Figure



3.3. Datum

The horizontal datum for this project is Kansas State Plane North (1501), North American Datum of 1983 (NAD 83) in U.S. survey feet. The vertical datum for this project is North American Vertical Datum of 1988 (NAVD 88), in U.S. survey feet. Ellipsoid heights acquired by Global Positioning System (GPS) were converted to NAVD 88 using GEOID18. All survey control was connected to the National Geodetic Survey (NGS).

3.3.1. Datum Conversion

For the purposes of this analysis, the approximate conversion between the National Geodetic Vertical Datum of 1929 (NGVD 29) and NAVD88 is +0.41 feet. Therefore, an NGVD 29 elevation of one foot would be assumed to be identical to a NAVD 88 elevation of 1.41 feet. Datum conversion was determined using the U.S. NGS Coordinate Conversion and Transformation Tool. All elevations referenced in this report are NAVD 88 unless stated otherwise.

3.4. Survey Methods

A topographic survey was completed by Stockwell Engineers Inc. from February 2023 to April 2023. NGS point R328 was used to establish the elevation of CP-01 toward the south end of the

site near 9800 W. 62nd Terrace (known as Skate City). Two separate Online Positioning User Service (OPUS) solutions were performed on the point to obtain an accurate position. Checks were then completed on NGS points R328 and Shawnee2.

All survey field notes were kept in a field book and given to USACE electronically. Manhole Information Sheets were also kept to document the interior of manholes with depths to inverts, size and material of pipes, and present use.

Underground utility locates were requested through Kansas State One Call System multiple times by Stockwell Engineers, Inc. during their ground survey efforts but limited locates were marked in the field. USIC, LLC was the utility location contractor through Kansas State One Call. Stockwell Engineers Inc. contacted all utility companies that were part of the Kansas State One Call System and spoke with representatives of the companies to obtain their locating contractor to mark the lines in the field.

A ground penetrating radar (GPR) investigation was also conducted between 20 through 24 February 2023 at six locations within the project area. According to the Environmental Protection Agency (EPA) these locations have existing or abandoned underground storage tanks (UTSs).

GPR identified eight underground void shapes within the project area. Table 3.3 summarizes these GPR locations.

Table 3.3. Ground Penetrating Radar Investigation Summary

GPR Number	Approximate Depth (feet)	Approximate Surface Area (square feet)	Approximate Location along UTC Alignment	Bank (Left or Right)
1	Undetermined	103.6	26+75	R
2	4.5	235.8	28+00	R
3	3.3	89.1	29+75	R
4	Undetermined	319.3	53+30	R
5	5.2	77.7	53+50	R
6	1.9	13.8	64+00	R
7	Undetermined	133.7	62+50	L
8	3.3	55.7	63+00	L

Stockwell completed a boundary survey in September 2023. The boundary survey deliverable included written legal descriptions for all parcels within the project area, closed boundary lines in MicroStation, and title reports for 160 parcels.

Project extents near Turkey Creek Tributary F and the proposed detention basin have expanded since the 2023 topographic survey request. LiDAR data from Johnson County Automated Information Mapping System (AIMS) was used to supplement the topographic survey in areas outside the survey extents where there are proposed project features. The LiDAR was acquired in November 2020 by Airborne Imaging. LiDAR date is in horizontal datum Kansas State Plane North and vertical datum NAVD 88.

4.0 HYDROLOGY AND HYDRAULICS

4.1 Hydrology

Hydrology used for design of the levee profile was previously developed as part of a 2005 Johnson County hydrologic study using Hydrologic Engineering Center 1 (HEC-1), which was a precursor to Hydrologic Engineering Center Hydrologic Modeling System (HEC-HMS). HEC-1 is a software that simulates infiltration and runoff in a watershed or network of watersheds due to an input storm event. Runoff hydrographs can be generated at desired locations to serve as frequency inflow hydrographs for hydraulic modeling in Hydrologic Engineering Center River Analysis System (HEC-RAS).

Rainfall frequencies used for the HEC-1 model to compute runoff were originally developed using the 24-hour precipitation maps included in the National Oceanic and Atmospheric Administration's (NOAA's) Technical Paper 40 (TP-40). In 2013, updated rainfall estimates for midwestern states were published by NOAA in a report titled, *NOAA Atlas 14–Precipitation Frequency Atlas of the United States–Volume 8: Midwestern States* (Atlas 14). This occurred during the USACE Upper Turkey Creek Feasibility Study (FS), which used the 2005 Johnson County study hydrology. It was suggested to use these updated precipitation frequency depths from Atlas 14 and generate updated frequency flows in the HEC-1 model. The annual maximum series was used for precipitation depths from a single point location for all frequencies. The single point location was determined to be suitable as all locations within the upper portion of the watershed used the same Atlas 14 precipitation depths. Table 4.1 provides a comparison of the precipitation frequency depths for Turkey Creek watershed with a 24-hour storm duration. Note the Atlas 14 precipitation depths were larger for all frequencies when compared to the TP-40 values.

Table 4.1. Annual Exceedance Probability and Precipitation Totals for 24-hour Storm Events at Turkey Creek.

AEP	Return Interval (years)	Precipitation Depth, TP-40 (inches)	Precipitation Depth, Atlas 14 (inches)
50%	2	3.6	3.7
20%	5	4.5	4.7
10%	10	5.3	5.5
5%	25	6.2	6.8
2%	50	6.9	7.8
1%	100	7.8	8.8
0.5%	200	8.4	9.9
0.2%	500	9.3	11.4

Table 4.2 summarizes the hydrologic parameters used in the HEC-1 model. Atlas 14 precipitation depths replaced the original TP-40 precipitation depths to generate the updated rainfall runoff flow hydrographs. The flow hydrographs were computed at various locations along Upper Turkey Creek to serve as inflow hydrographs in the HEC-RAS hydraulic models for the feasibility study. These same flow hydrographs and locations are being used with the current 1D and 2D hydraulic models for this study. Appendix E.1 summarizes inflow boundaries and locations while Appendix E.2 contains inflow hydrographs.

Table 4.2. Feasibility Report HEC-1 Modeling Parameters.

Process	Parameter	Data Source
Precipitation	Hypothetical Storm	Atlas 14 Precipitation Depths
Infiltration	SCS Curve Number Method	2005 Johnson County Hydrologic Study
Transform/Runoff	SCS Dimensionless Hydrograph	2005 Johnson County Hydrologic Study
Flow Routing	Muskingum-Cunge	2005 Johnson County Hydrologic Study
	Modified Puls	2005 Johnson County Hydrologic Study

4.2 Hydraulics

A fully 2D model was developed by Stantec on behalf of Johnson County, Kansas who is acting as a Cooperating Technical Partner (CTP) with the Federal Emergency Management Agency (FEMA). The purpose of the model, developed in HEC-RAS version 6.5, is to develop base flood elevations and floodplain boundaries for the streams within the Turkey Creek watershed. Stantec has provided this model for USACE use in the concurrent Upper Turkey Creek design project. The 2D rain-on-grid model was developed to perform both hydrologic and hydraulic computations and provide rainfall runoff flood mapping as well as the hydraulic response of Turkey Creek from local inflows. This model was adopted moving forward for 50% design.

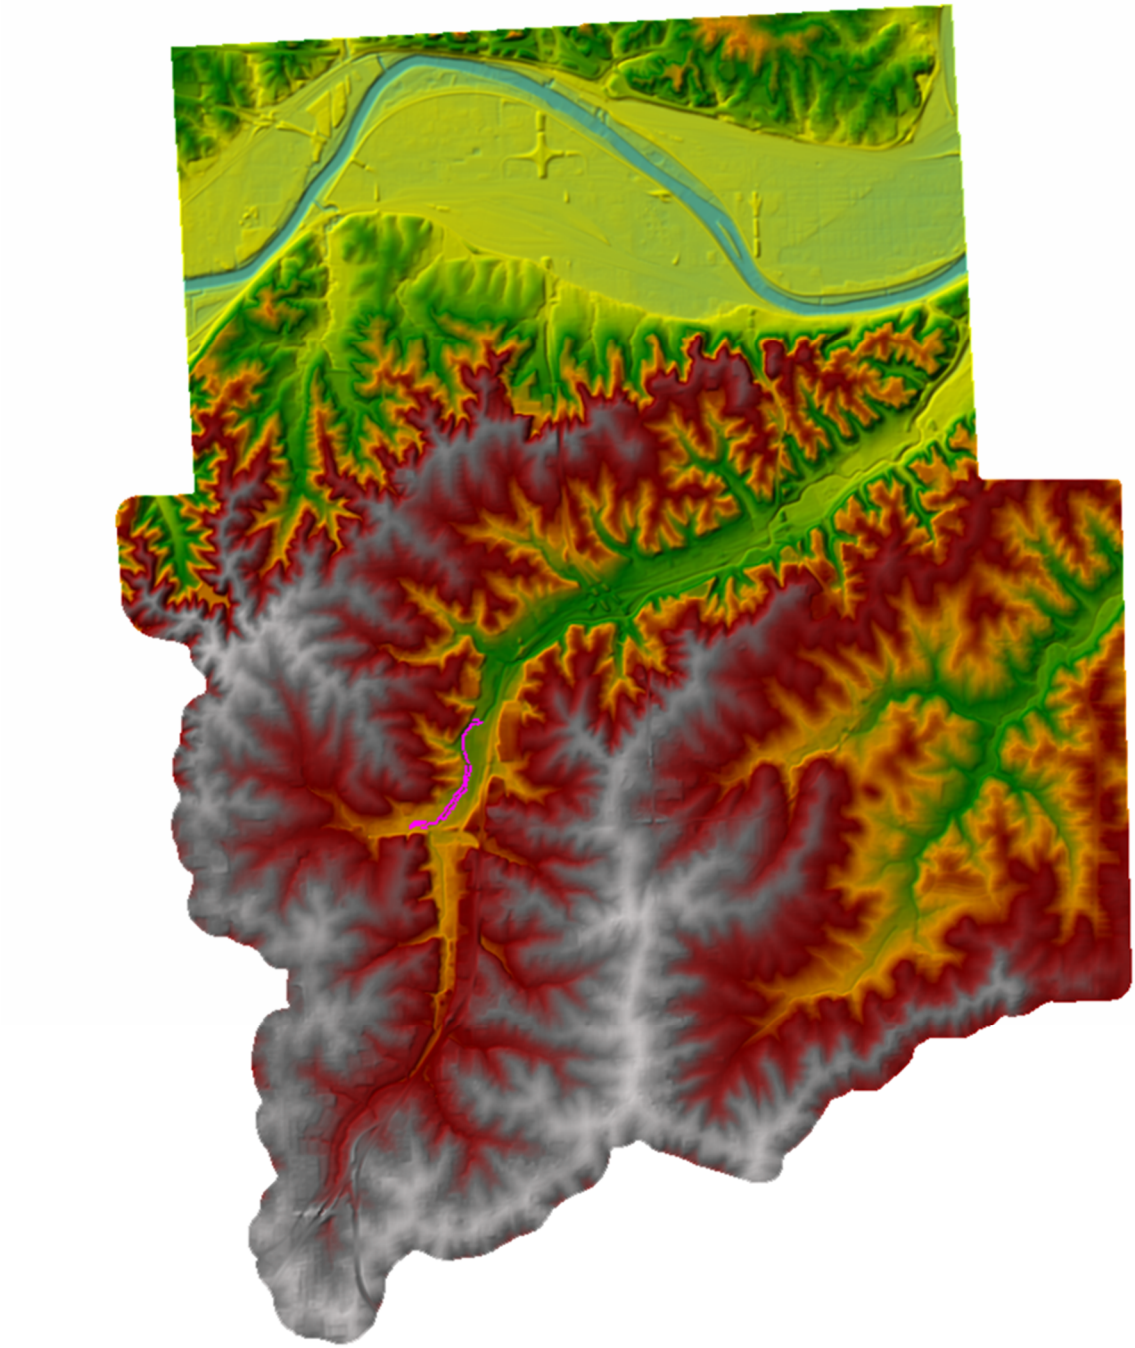
The original development of this model is documented in Appendix E.7, which contains Stantec's Turkey Creek 2D Watershed H&H Report. Appendix E.1 contains information on the modifications of the Stantec 2D model to suit the purposes of this design project.

Terrain data was provided by Johnson County through the Automated Information Mapping System (AIMS) for Turkey Creek and Brush Creek (2-ft resolution). The LiDAR was flown in December of 2020. For the portion of Turkey Creek that is outside of Johnson County, located in Wyandotte County, supplemental LiDAR was downloaded from Kansas' Data Access and Support Center (DASC) at 1-meter resolution. The LiDAR acquired from DASC was collected in 2018. The DASC LiDAR was reprocessed to match the resolution of the Johnson County LiDAR and were mosaiced together.

Cross-sectional channel survey was collected along Turkey and Brush Creeks. This channel bathymetry was burned into the terrain where differences in survey and LiDAR indicated that the LiDAR was not capturing the true channel bottom. The channel survey was interpolated and merged with the LiDAR to account for the additional conveyance not captured in the LiDAR. For Turkey Creek, surveyed cross-section locations showed little to no difference between the surveyed elevations and the LiDAR suggesting that the LiDAR was flown during a low-flow condition in the channel and adequately captures the channel conveyance. The survey was incorporated into the final 2D model terrain, interpolating between survey locations, and retaining only survey locations where the hydro-flatted LiDAR was higher than the survey.

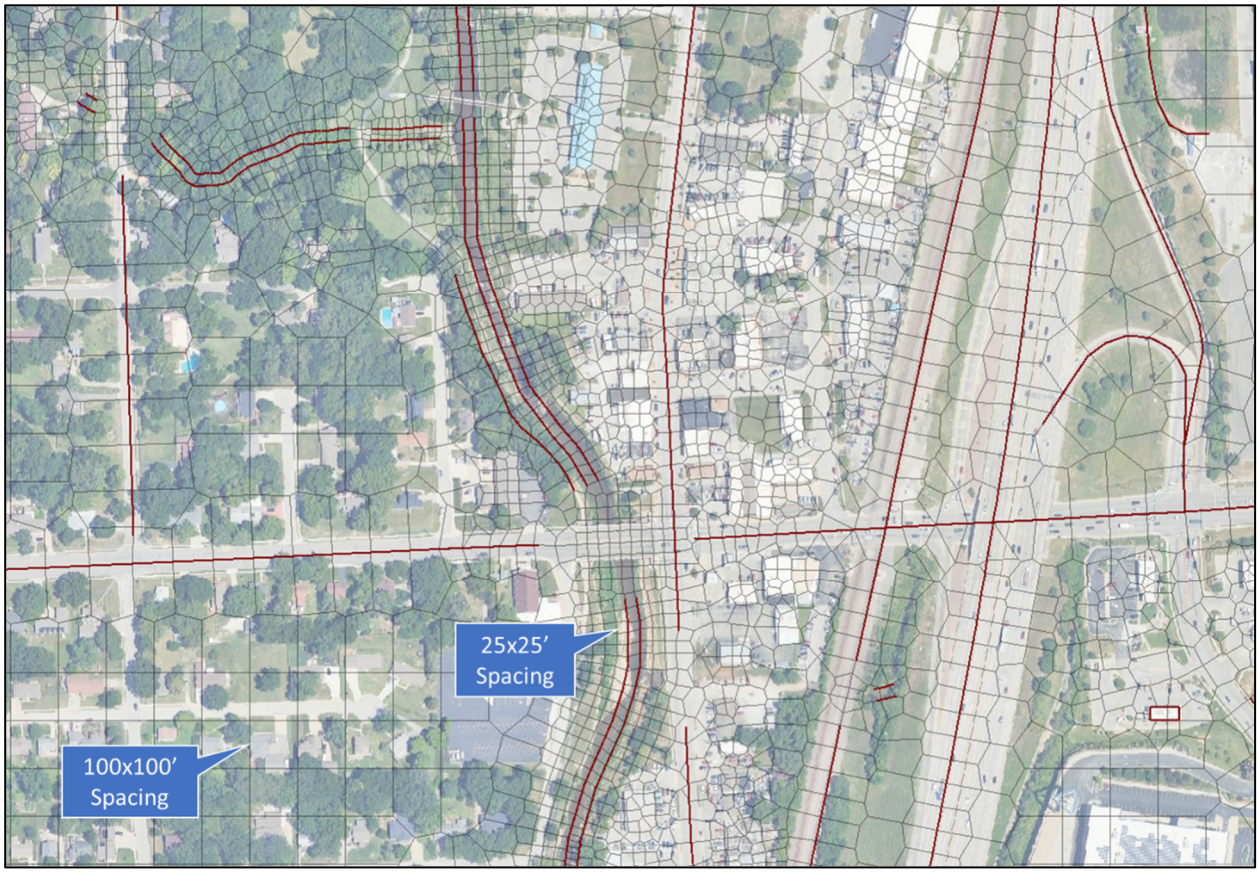
Figure 4.1 shows the terrain and proposed flood protection alignment in pink. The terrain encompasses almost the entirety of the Turkey watershed.

Figure 4.1. Terrain used for Hydraulic Modeling.



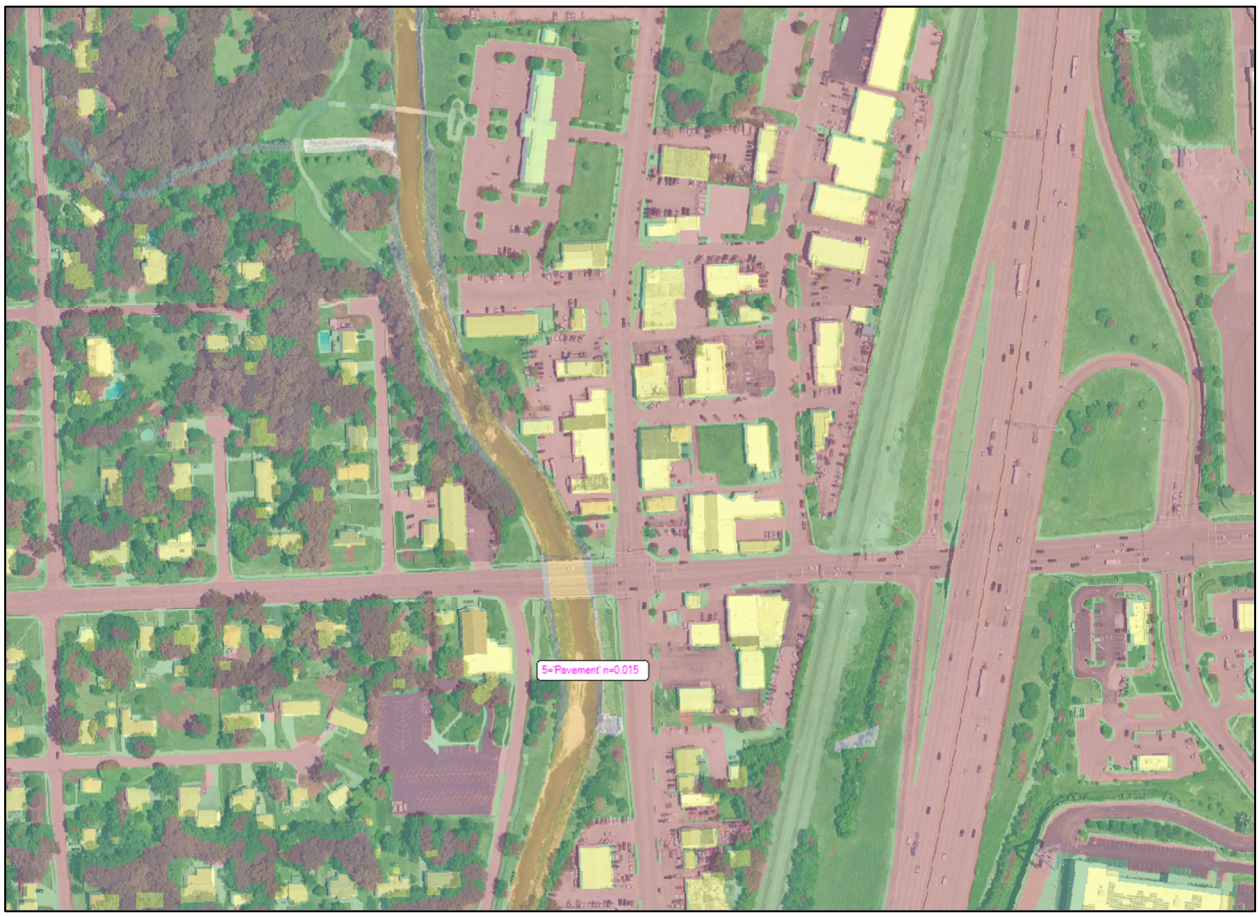
The HEC-RAS 2D mesh generally used cell sizes of 25x25 feet for the channel and 100x100 foot cell sizes for the floodplain. Breaklines were utilized to enforce high ground and better align cells to flow directions. Figure 4.2 provides an example of the 2D mesh.

Figure 4.2. Example of 2D Mesh in Project Area.



A custom land cover layer from the original Stantec model development was utilized for the design model. The layer acknowledges pavement and building footprints as well as channels. This is ideal given the smaller and heavily urbanized nature of the project area. The National Land Cover Database (NLCD) land cover layer was too coarse for the project area and was not used. Figure 4.3 provides an example of the land cover layer.

Figure 4.3. Example of Land Cover Layer.



4.2.1 Calibration/Validation

Stantec conducted calibration and validation of the 2D hydraulic model during original development, which was documented in their modeling report, attached in Appendix E.7. The model was calibrated with August 22, 2017, and May 28, 2020, events and the July 2017 event was used for validation. It should be noted that calibration and validation of the FEMA model was completed using gridded precipitation of these historic events. There is no observed gage flow to serve as model inflows nor as calibration points. USACE found general uncertainty in the efficacy of channel and floodplain calibration of this model due to the use of rain-on-grid in such an urban area and a lack of stormwater modeling which significantly impacts routing times and volume accumulation. For this reason and to account for uncertainty, Manning's n-values for the channel were increased from 0.025 to 0.035 to account for any potential for underestimation of stages during levee profile design. The channel has seen sediment deposition over the last decade, so these changes were deemed appropriate.

Additionally, Manning's n-values meant to represent buildings were initially set to 1.0 in the model. This is typically only appropriate if cells with a 1.0 roughness value are exactly encompassing the building footprint. Otherwise, the large 1.0 value significantly skews the roughness where flow should be able to actively convey. In these situations, the HEC-RAS

user's manual recommends setting the roughness values of buildings in the 2D mesh to 0.5. Since cells were not specifically configured to represent only the building footprints, the building roughness value was changed to 0.5. Cell alignments within the channel and around critical areas were improved.

The model cannot be calibrated in a non-rain-on-grid configuration due to the previously mentioned lack of observed flow data. This represents a major uncertainty in the hydraulics. HEC-RAS best practices were considered, and geometries were developed in such a way to lean towards conservatism given the lack of calibration data. As of the 50% design submittal, there are no remaining active flow gages downstream of the project area. While recent high water marks were collected for the July 2025 flood event, no gages along Turkey Creek recorded a peak flow estimate to correspond to the surveyed stages. Additionally, given recent findings (Appendix E.1.2) that Turkey Creek flooding seems to be primarily driven by the most intense 1-2 hours of any given storm, the 24-hour inflow hydrographs used for design are not applicable for comparison to observed storm data.

4.3 Levee Profile Design

The goal of the flood protection system is to protect against the 1% AEP design event with an assurance level of 85% and to meet the criteria set forth by FEMA to accredit the levee for the National Flood Insurance Program (NFIP). Criteria for accreditation can be found in FEMA 44 CFR 65.10.

Development of the levee profile is a multi-stage effort. Levee height is determined through risk-based analysis outlined in EM 1110-2-1619. Hydrologic Engineering Center Flood Damage Reduction Analysis (HEC-FDA) software is used to determine levee height with a required assurance level based on HEC-RAS model outputs. This includes the following sets of data for both the FWOP and with project conditions at each index location:

- Unsteady HDF plan files
- Frequency Functions (Flow Frequency Curve)
- Stage Transform Functions (Rating Curve)
- Lateral Structures (Levee Alignment Shapefile)

Each item is discussed in further detail in Appendix E.1 while Appendix E.3 contains the HEC-FDA input data. The following sections detail the adopted levee profile for 50% design and considerations for future levee profile design.

4.3.1 Adopted Levee Profile

After H&H inputs were created, an estimated levee height was entered at each index location. HEC-FDA performed a monte-carlo analysis, randomly sampling points within the uncertainty bounds of the flow frequency curve and stage-discharge rating curve. HEC-FDA then computed an assurance level based on the resulting expected 1% AEP water surface elevation and the freeboard from the estimated levee height. Levee height iteration was necessary to reach the 85% assurance level threshold at each index location.

The 85% assurance levee heights for each index location were pulled from the HEC-FDA outputs and assembled in tabular and graphical format to create the updated levee profile. It should be noted that the levee profile increased or decreased in some locations compared to the previous post-35% levee profile. To minimize redesign, the post-35% levee profile was kept

(also documented in Appendix E.3), only modifying it where the 50% HEC-FDA run showed increases in height. The table below provides elevations for the left and right bank systems. Generally, any notable increase in levee height from post-35% design was due to incorporation of superelevation. The post-35% design originally assumed the same levee elevations on both the left and right bank, disregarding superelevation impacts. A comparison of profiles is shown below in Figure 4.4.

Table 4.3. Adopted Levee Profile for 50% Design.

Left Bank*		Right Bank	
STA (feet)	**Elevation (feet)**	**STA (feet)**	**Elevation (feet)**
65+66 W	910.1	65+66 E	911.5
64+14 W	912.6	64+14 E	912.8
62+70 W	913.8	62+70 E	913.8

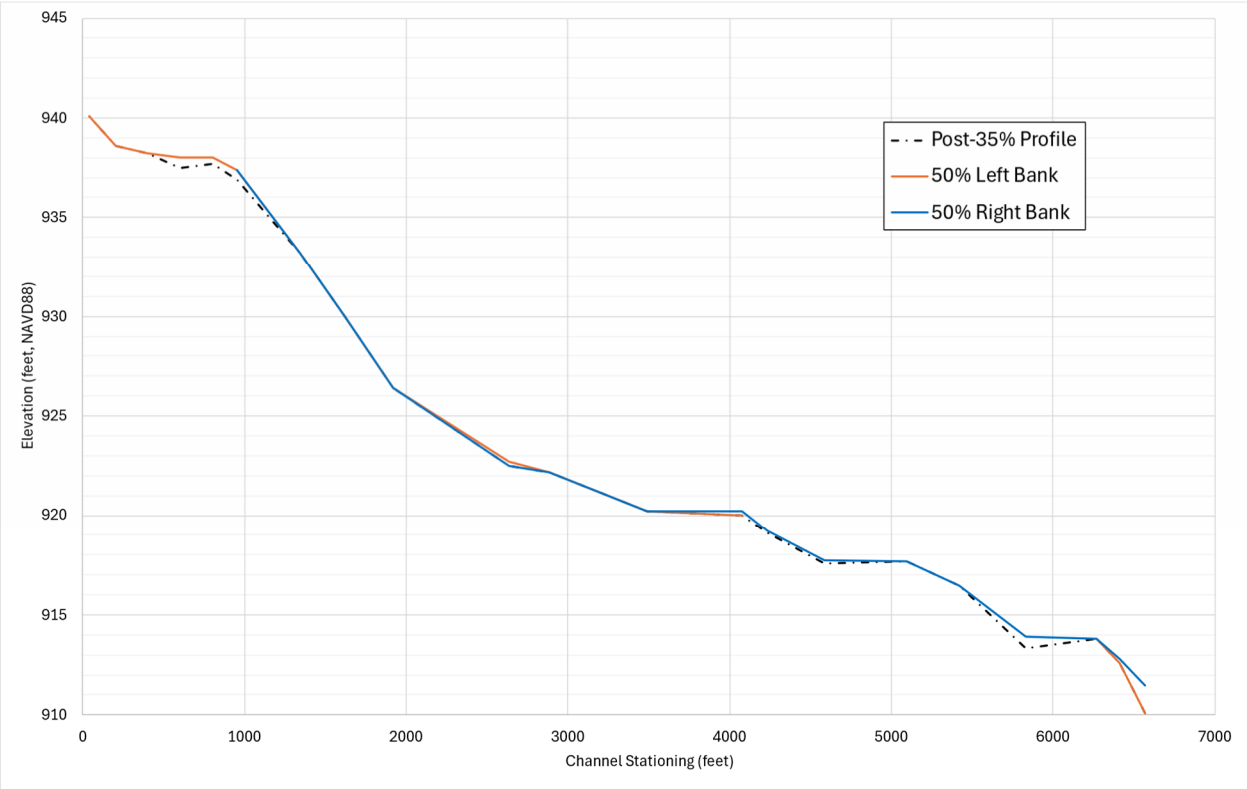
6+00	938.0		
4+00	938.2		

**Note: Left bank is not continuous, and grey boxes represent high ground with no levee/floodwall.*

Figure 4.4. Adopted 50% Levee Profile Comparison with Post-35% Profile.



4.3.2 Future Levee Profile Design

Given that the project is being paused at 50% design, future considerations for changes in levee heights should be documented. The post-35% design left bank included continuous flood protection from project channel station 0+00 to 40+76 (Johnson Drive bridge). The left bank design was then revised prior to 50% submittal to provide protection only to the businesses from channel stations 3+00 to 20+00 and around the church adjacent to Johnson Drive. This change necessitated re-running the assurance computations in HEC-FDA at locations where water surface elevations increased in order to maintain an assurance level of 85%. Index locations where levee height increases are necessary in future design iterations are shown in red in Table 4.4. Figure 4.5 *shows the changes in flood protection alignment from post-35% (blue centerline) to 50% design (red centerline). It should be noted that design changes to the left bank generally resulted in decreases in water surface profile for the 1% AEP event, with the average change in water surface profile along the project extents being -0.17 feet. A comparison of the 50% design levee profile with the potential future profile is shown in*

.

<u>Recommendation</u>

While a levee profile was computed to inform post-50% design, it is recommended that a full re-computation of the levee profile be completed in HEC-FDA should design resume in the future. Project area conditions or design guidance may have changed since the 50% design submittal. Additionally, consideration should be given to refinements of index locations. Additional index locations and/or adjustments to spacing may be necessary to best represent superelevation throughout the system.

Figure 4.5. Changes in Flood Protection Alignment from Post-35% (red) to 50% Design (blue).

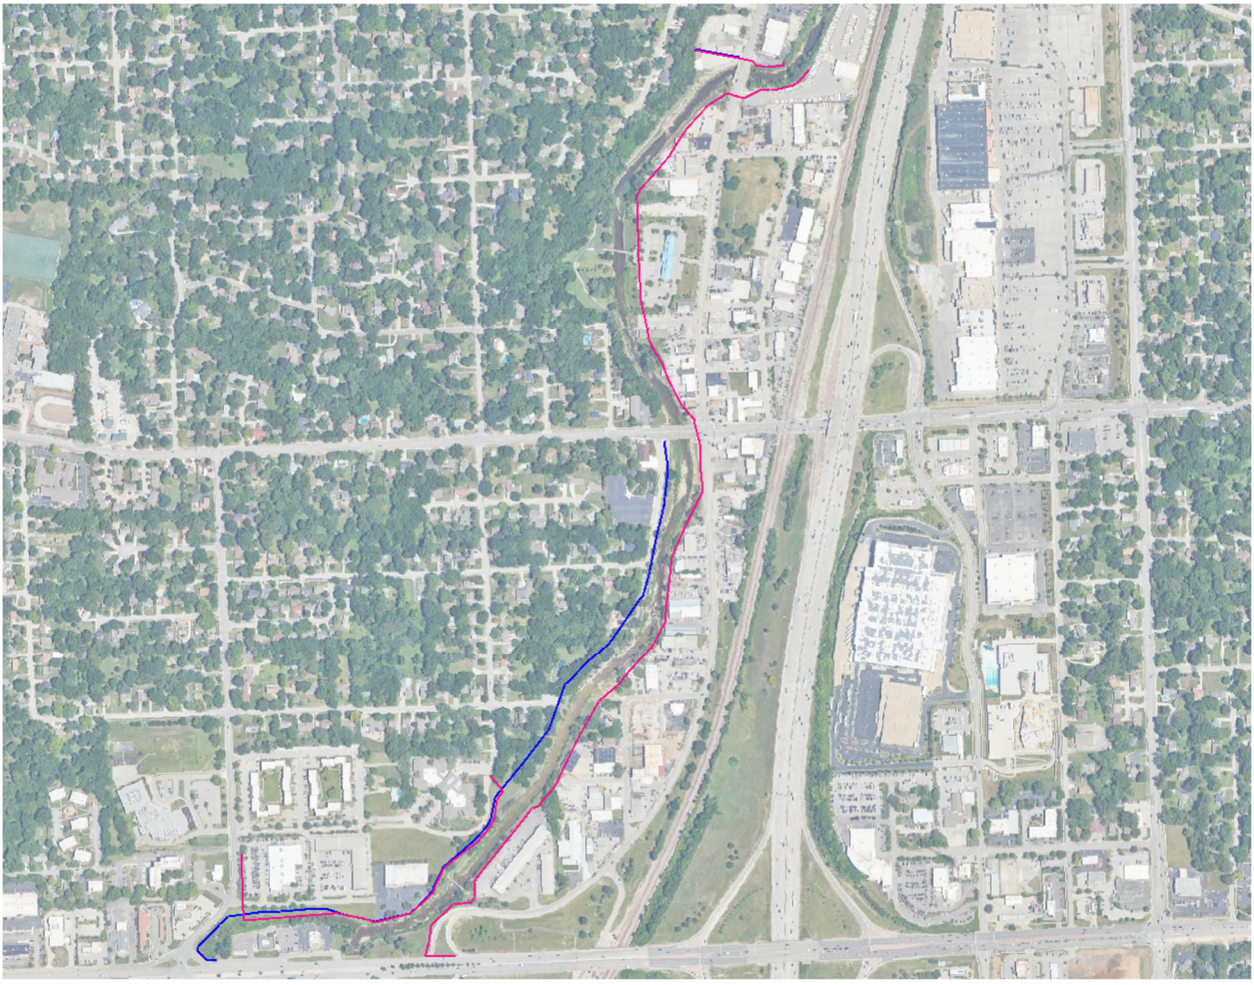


Table 4.4. Future Levee Profile – Increases shown in red, potential decreases not yet evaluated.

4+00	938.2		

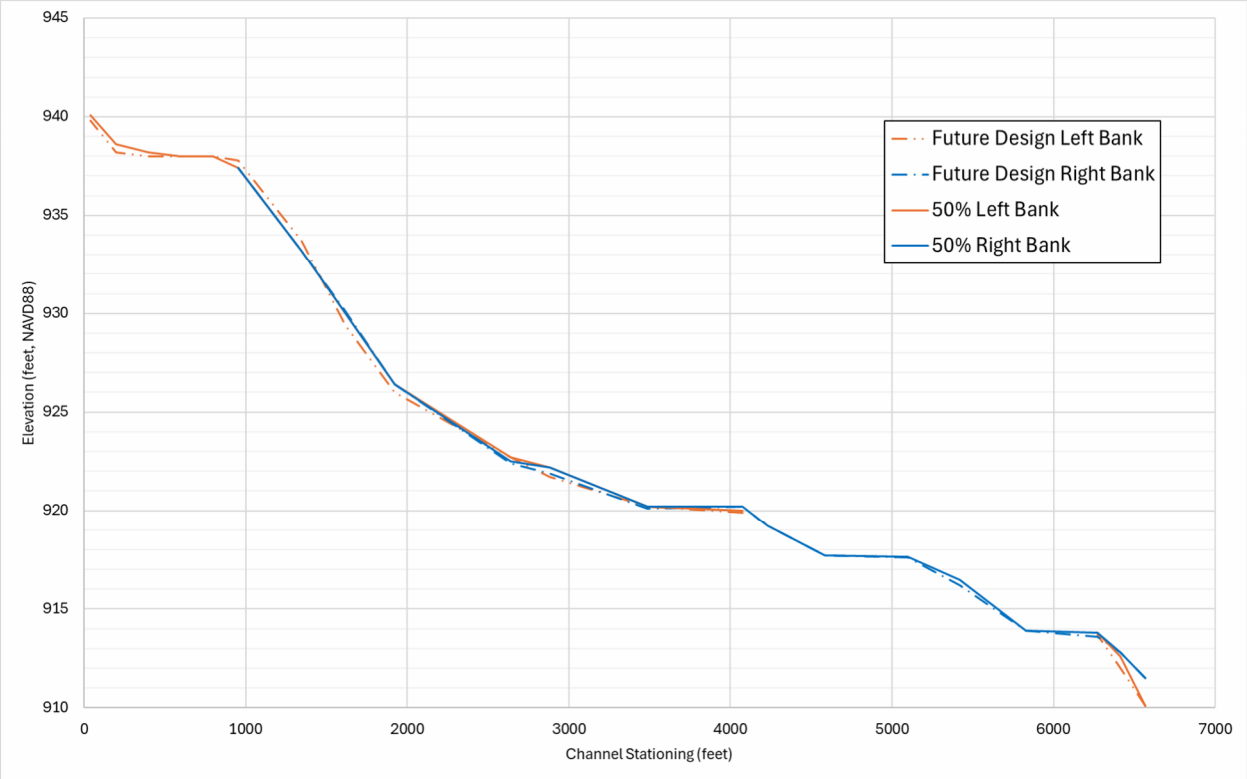

Figure 4.6. 50% vs Future Design Comparison of Levee Profiles.

4.3.2.1 Managed Overtopping

A designated overtopping location was initially considered to follow criteria set out by Engineering and Construction Bulletin (ECB) 2019-8. The guidance generally recommends implementing levee superiority, which means to select a reach of the levee to overtop first where risks to life safety or property are least prevalent. But given the highly urbanized nature of the proposed flood protection system, all locations behind the flood protection system would likely result in immediate flood inundation of private or commercial property. Consideration was given to the location of the detention pond discussed later in Section 5. But any event large enough to result in overtopping of the levee would also result in completely filling the detention pond under gravity denied conditions and would result in overtopping flow spreading out around downtown Merriam.

With this information in mind, it was decided to leave the levee profile as is with the 85% assurance profile which would result in balanced overtopping. Future consideration should be given to implementing a designated overtopping location if the project is resumed and the City of Merriam has a master plan for the redevelopment of the downtown area that might allow a safe and low consequence overtopping location.

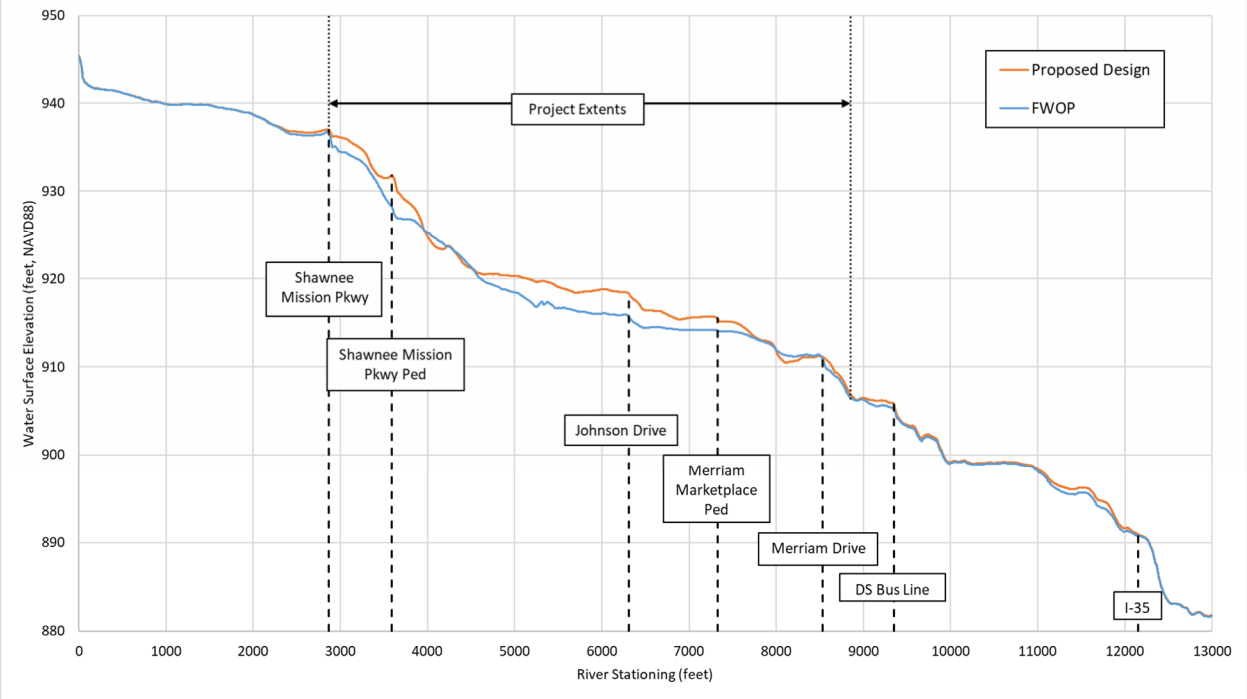
4.4 Comparison of Levee Design to FWOP

The following sections provide a comparison of hydraulic conditions between the 50% design results and the FWOP results. This includes water surface profile for the 1% AEP design event, channel velocities, and water surface elevations. Flow and stage hydrographs are provided at each bridge location in Appendix E.6.

4.4.1 Channel Profile

The hydraulic model was used to evaluate the water surface profile changes from Future Without Project (FWOP) conditions along the project extents at various project features discussed in Section 2. Figure 4.7 compares water surface profiles between FWOP conditions and proposed design. As expected, the water surface profile generally increased within the project area, between Shawnee Mission Parkway and Merriam Drive. The average increase in water surface elevation for this stretch is approximately 1.24 feet with a maximum increase of 3.7 feet on the upstream face of Shawnee Mission Parkway Pedestrian Bridge.

Figure 4.7. Water Surface Profile Comparison between FWOP and Proposed Design.



4.4.2 Channel Velocities

Channel velocities were evaluated within the project extents for the FWOP and 50% design conditions for the 1% AEP design event. Maximum channel velocities for both scenarios generally range from 7-19 ft/s along the project length. Velocities were most extreme near the pedestrian bridge just downstream of Shawnee Mission Parkway, peaking at 18.5ft/s (Channel STA 14+30) for FWOP. Channel velocity at bridges for the 50% design decreased when compared to FWOP as seen in Table 4.5.

Table 4.5. Peak Channel Velocities at Bridges.

Bridge	Location	FWOP Velocity (feet/sec)	50% Design Velocity (feet/sec)
Shawnee Mission Parkway Bridge	Upstream	7.9	7.2
	Downstream	9.4	7.1
Shawnee Mission Parkway Pedestrian Bridge	Upstream	18.4	16.3
	Downstream	18.5	15.9
Johnson Drive Bridge	Upstream	9.9	8.8
	Downstream	9.7	9.2
Merriam Marketplace Bridge	Upstream	8.8	8.3
	Downstream	10.1	9.3
Merriam Drive Bridge	Upstream	11.1	10.9

	Downstream	12.2	10.0

The 50% design velocities increased relative to FWOP most notably in narrow straightaways where flow is fully constrained to the channel and no longer allowed to spread into the floodplain. Figure 4.8 provides a velocity profile plot. Spikes above FWOP are located at channel stations 18+70, 46+80, 58+90, and 66+80. Figure 4.9 and Figure 4.10 provide velocity grids for the FWOP and 50% design, respectively.

Figure 4.8. Channel Velocity Profile Plot for 1% AEP Event – FWOP vs. 50% Design.

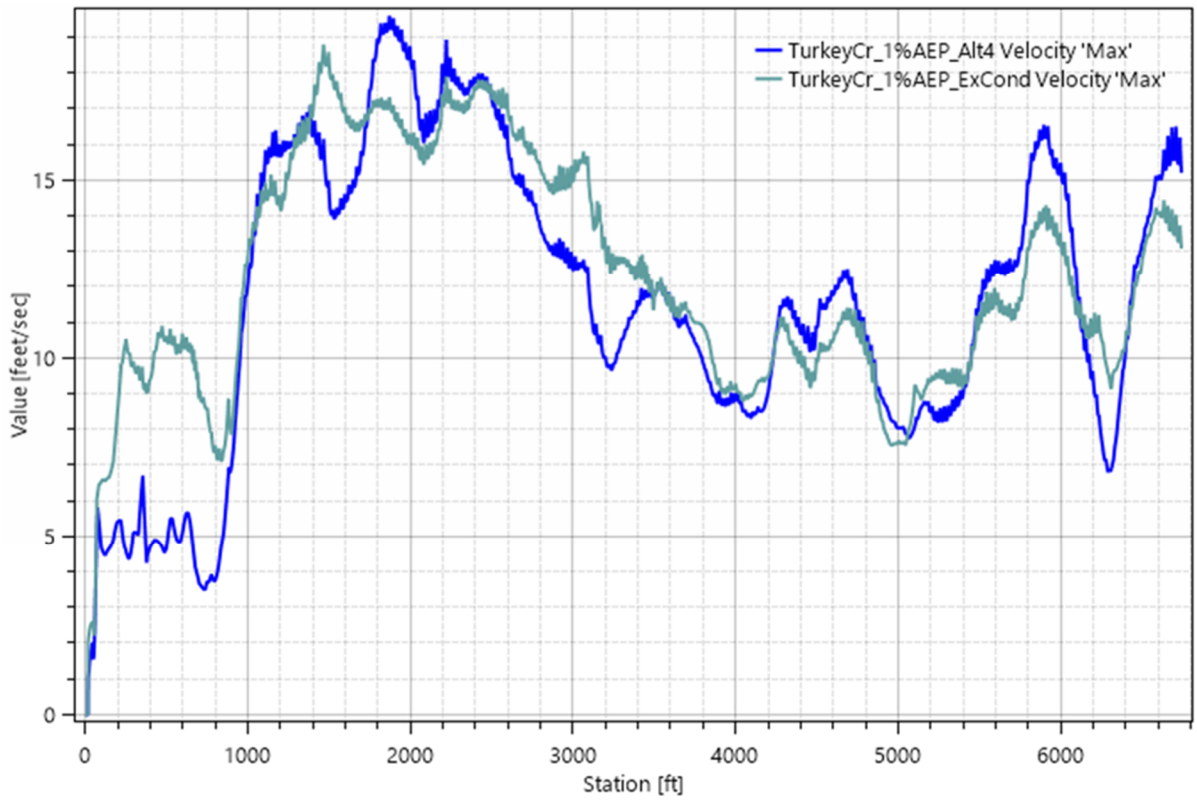


Figure 4.9. FWOP Peak Velocity for 1% AEP Event.

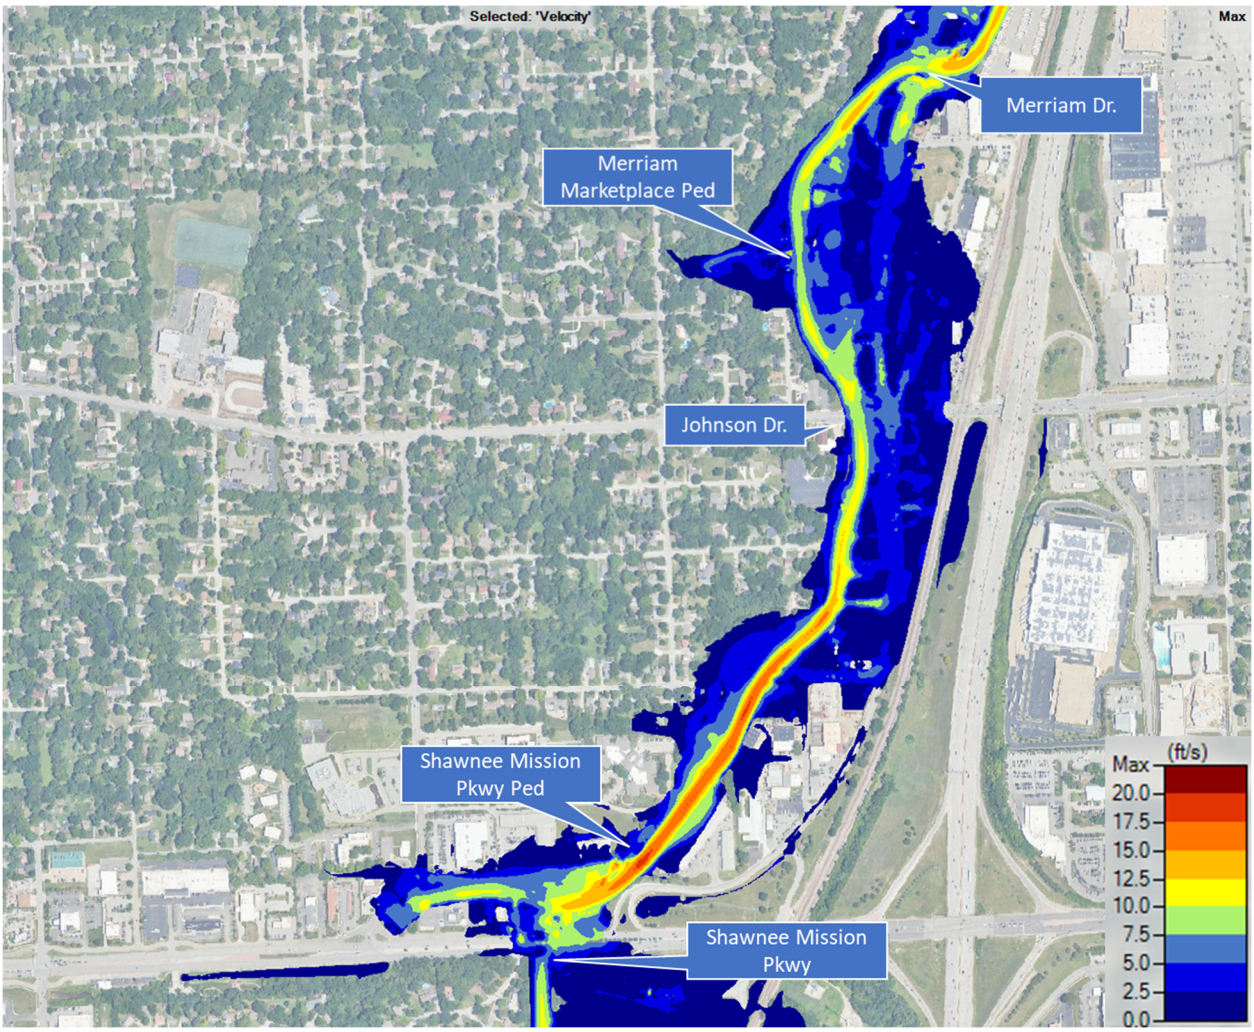

Figure 4.10. 50% Design Peak Velocity for 1% AEP Event.

4.4.3 Bridge Water Surface Elevations

Water surface elevations for the 1% AEP event were taken at the upstream and downstream side of each bridge to better inform the suitability of the existing bridges and inform potential bridge raises and/or replacements. Elevations were also taken from the 2D model for comparison in .

Johnson Drive and Merriam Drive bridges both have proposed replacements which allow increased flow conveyance. The increase in flow conveyance for the Merriam Drive bridge replacement design results in a decrease in water surface elevation on the upstream face. The other bridges still see an increase in water surface elevation from FWOP to the 50% design because of the flood protection system being in place and preventing floodplain conveyance. The upstream face of Shawnee Mission Parkway bridge has a much smaller increase because the bridge culvert is inlet controlled. Any increase in the water surface is because the 1% AEP event is already overtopping Shawnee Mission Parkway in the FWOP condition.

Table 4.6. Water Surface Elevations at Bridges.

Bridge	Location	2D Existing Conditions (feet)	2D 50% Design (feet)
Shawnee Mission Parkway Bridge	Upstream	936.51	936.89
	Downstream	935.14	936.24
Shawnee Mission Parkway Pedestrian Bridge	Upstream	927.96	931.62
	Downstream	926.86	929.92
Johnson Drive Bridge	Upstream	915.85	918.43
	Downstream	915.02	917.62
Merriam Marketplace Bridge	Upstream	914.16	915.64
	Downstream	913.99	915.1
Merriam Drive Bridge	Upstream	911.29	910.95
	Downstream	909.66	910.64
DS Bus Line Bridge	Upstream	905.2	905.73
	Downstream	903.71	903.84

4.4.4 Duration Analysis

A duration analysis was conducted for both the 1% AEP event and an incipient overtopping event to determine the duration of river stage above certain thresholds. These thresholds include channel capacity, levee toe, 1 foot of freeboard, and top of levee. It should be noted that the overtopping event provided an overtopping depth of 0.1 feet to determine the location of incipient overtopping. The location of incipient overtopping is on the upstream side of the Merriam Marketplace pedestrian bridge. The Merriam Marketplace is a open air pavilion with a parking lot surrounding it. This immediate area present a low risk to life safety and property, though any overtopping flow is likely to rapidly spread out and inundate downtown Merriam. Figure 4.11 provides a visual of the two event hydrographs and stage thresholds at the pedestrian bridge.

Table 4.7 summarizes the durations above the previously mentioned thresholds for both the 1% AEP and overtopping events. The results illustrate the flashiness of Turkey Creek, even for events as severe as an overtopping scenario for the proposed levee profile. In that scenario, the levee is loaded for less than 7 hours in total and within one foot of the top of levee elevation for approximately 3 hours.

Figure 4.11. Upstream Side of Merriam Marketplace Pedestrian Bridge 1% Annual Exceedance Probability and Overtopping Hydrographs.

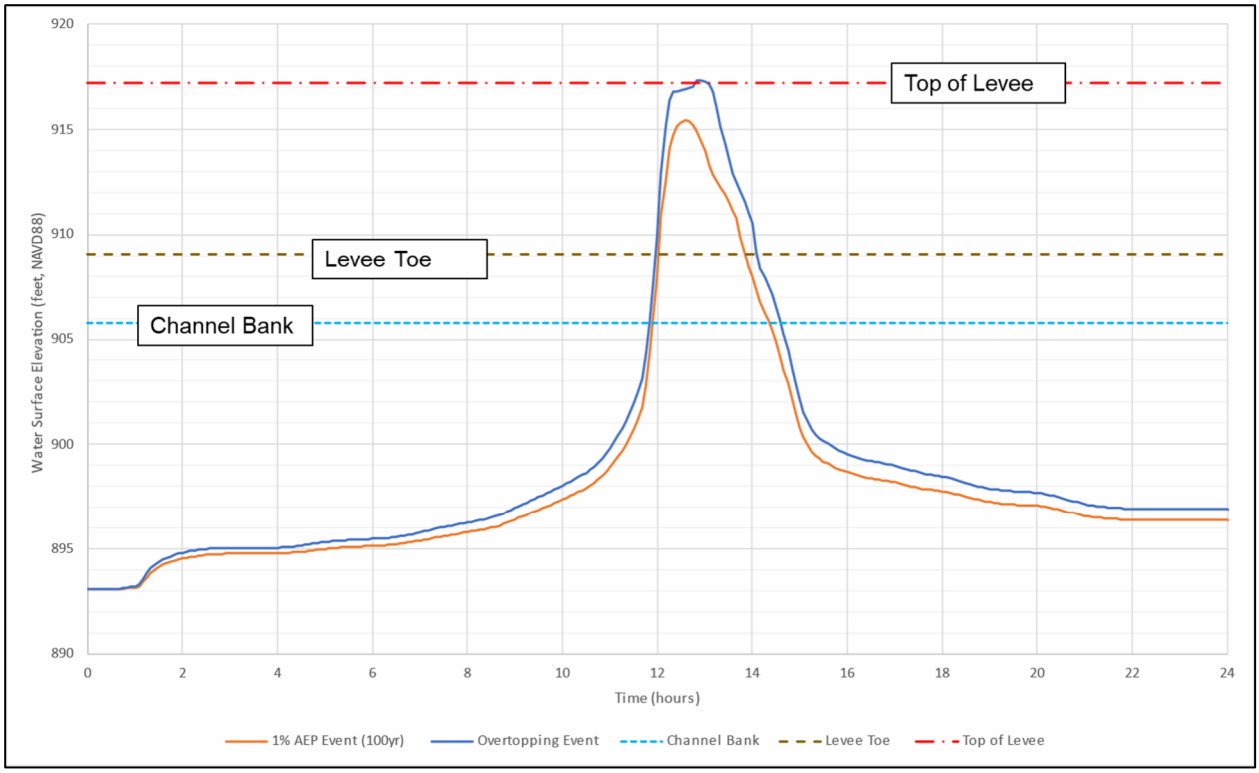

Table 4.7. Duration Analysis at Upstream Side of Merriam Marketplace Pedestrian Bridge.

Stage Threshold	Elevation (feet)	Duration Exceeded (hours) for 1% AEP Event	Duration Exceeded (hours) for Overtopping Event
Channel Bank	905.75	2.5	2.75
Levee Toe	909.05	1.75	2
1 foot of freeboard	916.22	0	1.25
Top of Levee	917.22	0	0.25

4.4.5 Stage Exceedance Analysis

An annual stage exceedance analysis was conducted using Statistical Software Package (HEC-SSP) to find the percent of time Turkey Creek exceeds a given stage (WSE) at the Turkey Creek at Johnson Drive Stormwatch river gage. Stage data is available back to 2001 at this gage location but data prior to 2014 is erratic with season-long shifts in normal flow stage and numerous erroneous gage readings. Therefore, stage data from 2014 onwards, plotted in Figure 4.12 and summarized in , was used for the analysis. The approximate levee toe stage at the right bank upstream side of Johnson Drive (location of Stormwatch gage) is shown, along with

the top of levee stage. According to the analysis, the levee toe would be loaded less than 0.1 percent annually at this location.

Figure 4.12. Annual Stage Exceedance Plot at Turkey Creek at Johnson Drive (Stormwatch TU04).

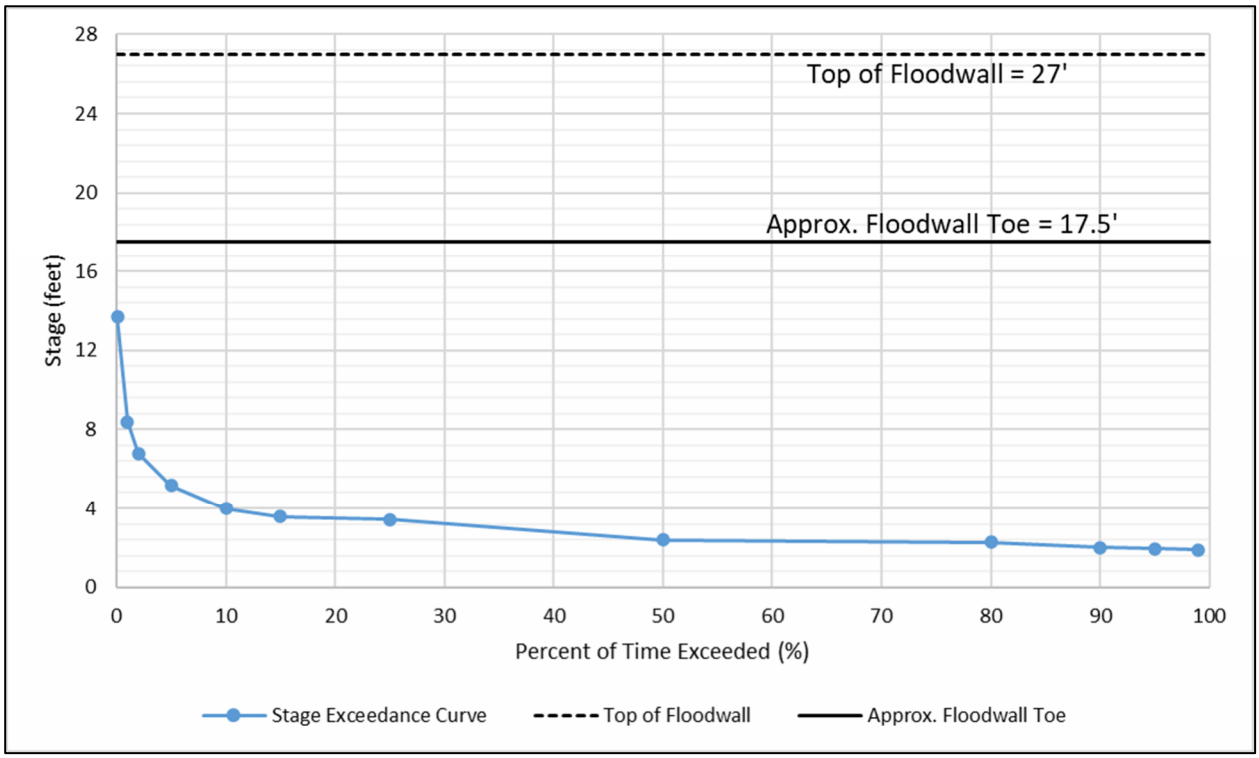

Table 4.8. Annual Stage Exceedance Summary at Turkey Creek at Johnson Drive (StormWatch TU04)

Percent of Time Exceeded	Stage (feet)	Water Surface Elevation (feet)
99.0	1.89	894.89
95.0	1.93	894.93
90.0	2.01	895.01
80.0	2.28	895.28
50.0	2.38	895.38
25.0	3.41	896.41
15.0	3.58	896.58
10.0	3.98	896.98
5.0	5.17	898.17
2.0	6.8	899.8

1.0	8.38	901.38
0.1	13.7	906.7

4.4.6 FEMA Flood Profile Comparison

This analysis is to be completed in a future design submittal as it is dependent on furthering of bridge design and finalization of levee configuration and alignment.

4.5 Riprap Sizing

Riprap sizing was determined by using the HEC-RAS hydraulic design tool which utilizes guidance outlined in EM 1110-2-1601. Maximum riprap diameter (D_{100}) is largely dependent on flow velocities and radius of curvature, as well as other factors. Required riprap sizes were determined for both the left and right banks to act as levee slope protection and toe protection for floodwalls. Riprap was sized at any location where notable changes in velocity occurred.

4.5.1 Parameters

The riprap sizing tool requires several input parameters based on the hydraulic results of the 1% AEP design event and the general geometry/configuration of the terrain and flood protection system. Table 4.9 below summarizes the parameters used for selecting riprap gradations and sizes. Radius of curvature and side slope angles were computed at each design cross-section location. EM 1110-2-1601 states the minimum factor of safety for riprap design is 1.1. But given that this is a life-safety project, a factor of safety of 1.5 was deemed more appropriate. Based on internal discussions and referencing other projects within the metro area, the typical stone unit weight can be sourced locally is 155 lb/ft^3. An angle of repose of 40 degrees was used which is stated as the typical value in EM 1110-2-1601.

Average channel velocity, hydraulic depth, and channel top width were all computed for both the upstream reference cross-section and each design cross-section. It should be noted that to incorporate higher confidence in maximum riprap diameter, the left or right overbank (depending on which is being evaluated) velocity was used instead of the average channel velocities. Given the higher fidelity of 2D modeling, spatially varied velocities across a cross section can be obtained as shown in Figure 4.13. Using this example, the velocity used in the riprap tool would be 12 ft/s for the right bank levee.

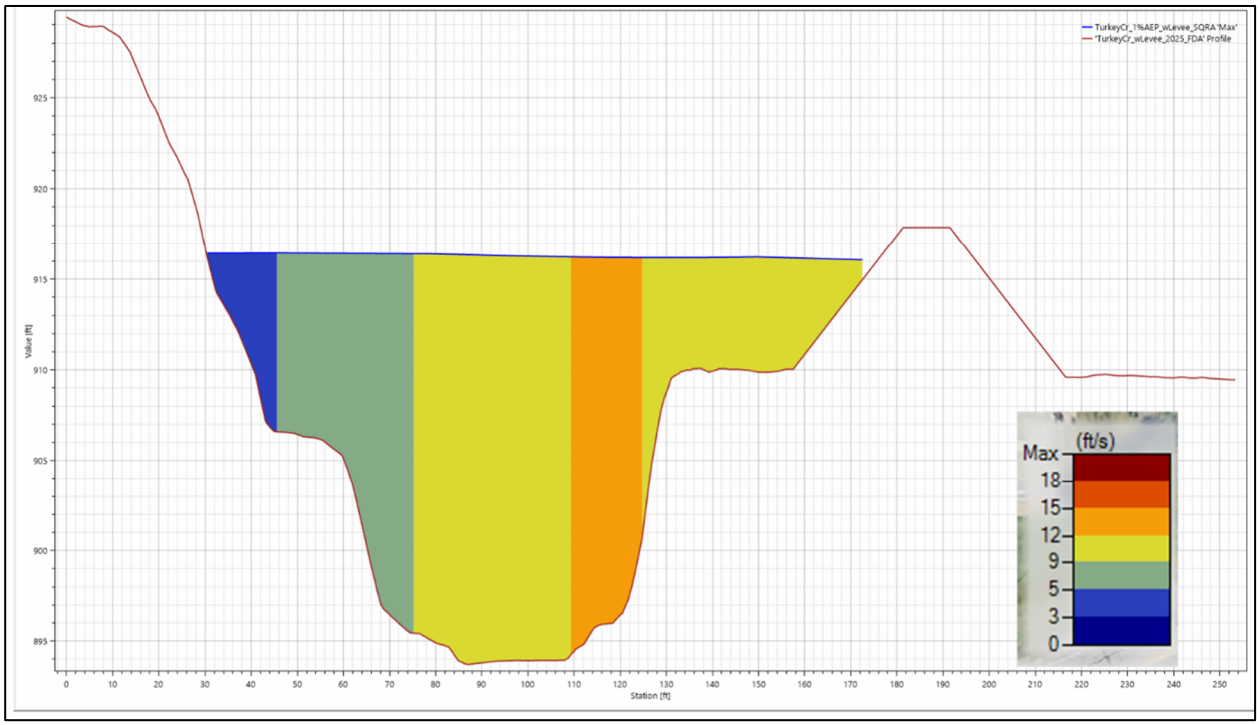
Riprap sizes can be computed using two methodologies in the HEC-RAS tool: The USACE method and the Isbash method. Default parameters were chosen for both, aside from channel alignment which was dependent on design cross-section location. Specific parameters for each design cross section are detailed in Appendix E.4.

Table 4.9. HEC-RAS Riprap Design Tool Parameters.

Input Data	
Parameter	**Value**
Radius of Curvature (ft)	*Varied*
Side Slope Angle (deg)	*Varied*
Safety Factor	1.5
Unit Weight (lb/ft^3)	155
Angle of Repose (deg)	40

Upstream Reference Cross Section	
Velocity Average (ft/s)	9.7
Hydraulic Depth (ft)	10.3
Width (ft)	80
Design Cross Section	
Velocity Average (ft/s)	*Varied*
Hydraulic Depth (ft)	*Varied*
Width (ft)	*Varied*
USACE Parameters	
Channel Type	Natural Channel
Rock Type	Angular Rock
Site Alignment	*Varied*
K1 Method	Graphical
Isbash Parameters	
Channel Alignment	*Varied*
Turbulence Value	1.2

Figure 4.13. Spatially Varied Velocities in Design Cross-Section.



4.5.2 Maximum Riprap Diameters

A total of six unique maximum riprap diameters were determined from the HEC-RAS tool and then condensed down to three to reduce design complexity. Table 4.10 and Table 4.11 provide the maximum riprap sizes for the left and right banks, respectively. The largest riprap required has a D_{100} of 42 inches. This is located downstream of the Merriam Drive bridge on the right bank which is a sharp outside bend. A 36-inch diameter was selected for this area due to the lack of local availability of 42-inch riprap. A D_{100} of 36 inches was deemed suitable as it retained a factor of safety of 1.3 which is still above the minimum factor of safety (1.1) specified in EM 1110-2-1601. Additionally, this section of the flood protection system is lower risk given the riprap is located at the downstream end of the project. Any floodwall failure at this location would result in backwater flooding which would act as a bathtub until river stages drop and water drains out of the interior through the breach. The bathtub effect occurs when backwater enters the downstream portion of a protection system and slowly fills rather than conveying through the leveed area. This presents less life safety risk than breaches that occur upstream and have hydraulic head to flow through the leveed area.

Numerous locations only required a D_{100} of 15 inches, but EM 1110-2-1601 specifies a minimum of ~18 inches (W_{100} of 80 lbs.) in urban areas to prevent theft and vandalism. So, all instances of 15-inch riprap were increased to 21 inches. 24- and 30-inch riprap was changed to 33-inch riprap to simplify design as previously mentioned.

Table 4.10. Maximum Riprap Sizing for Left Bank.

Approx. UTC STA		Approx. Left Bank STA		Length (ft)	Initial D100 (in)	Recommended D100 (in)
Start	End	Start	End			
0+00	9+00	13+00	22+38	938	21	21
9+00	14+00	22+38	26+50	412	33	33
15+25	19+00	28+20	31+60	340	15	21
21+00	25+00	34+00	37+60	360	15	21
33+00	36+00	45+40	48+45	305	15	21
63+00	65+75	78+40	80+76	236	24	33

Table 4.11. Maximum Riprap Sizing for Right Bank.

Approx. UTC STA		Approx. Right Bank STA		Length (ft)	Initial D100 (in)	Recommended D100 (in)
Start	End	Start	End			
15+25	19+00	6+80	10+47	367	15	21
19+00	26+00	10+47	17+60	713	15	21
30+00	33+00	21+40	24+75	335	30	33

53+00	57+00	44+80	48+12	412	21	21
57+00	60+00	48+12	51+30	318	33	33
60+00	64+00	51+30	54+60	320	21	21
64+00	65+75	54+60	57+78	318	42	36

4.5.3 Bridge Scour Analysis

A bridge scour analysis was conducted on the two pedestrian bridges within the study area. The Shawnee Mission Parkway pedestrian bridge and the Merriam Marketplace pedestrian bridge. Johnson Drive and Merriam Drive bridge designs are being contracted out and bridge scour analysis will be performed by the contractor.

The bridge scour analysis is to be conducted in accordance with the Federal Highway Administration (FHA) Hydrologic Engineering Circular No. 18. This document provides guidelines for evaluating scour at bridges. Cross-sectional channel info and hydraulic data was pulled from the HEC-RAS model for computing scour along bridge abutments only, given that neither pedestrian bridge had piers. Appendix E.5 contains the hydraulic input data used for the analysis. Section 9.6 of the DDR will contain the full bridge scour analysis in a future design submittal. Should riprap be required to mitigate any expected bridge abutment scour, the sizing will be documented in this section.

4.6 Channel Modifications

Modifications were made to the channel and overbanks along the tributary at the upstream portion of the project. After the decision was made to remove the flood protection from around the two existing businesses and instead buy them out The channel alignment would be shifted to the south and the left (north) bank would be built out to place a floodwall. This was done to avoid the need for utility relocations that run along W. 62nd Terrace. This provides minor additional storage and comes with the added benefit of creating a local borrow source. Figure 4.14 provides a visual of the benching, and Figure 4.15 shows a cross-section of new channel alignment and minor benching.

The realigned channel is to have a 55-foot bottom width which is generally slightly wider than the existing channel bottom width. The channel banks will have 3H:1V bank slopes for stability. The channel profile will be generally maintained to facilitate continued drainage from the upstream culverts and to still terminate at the downstream concrete encase utility crossing at the confluence with the Turkey Creek channel.

Figure 4.14. Tributary Benching

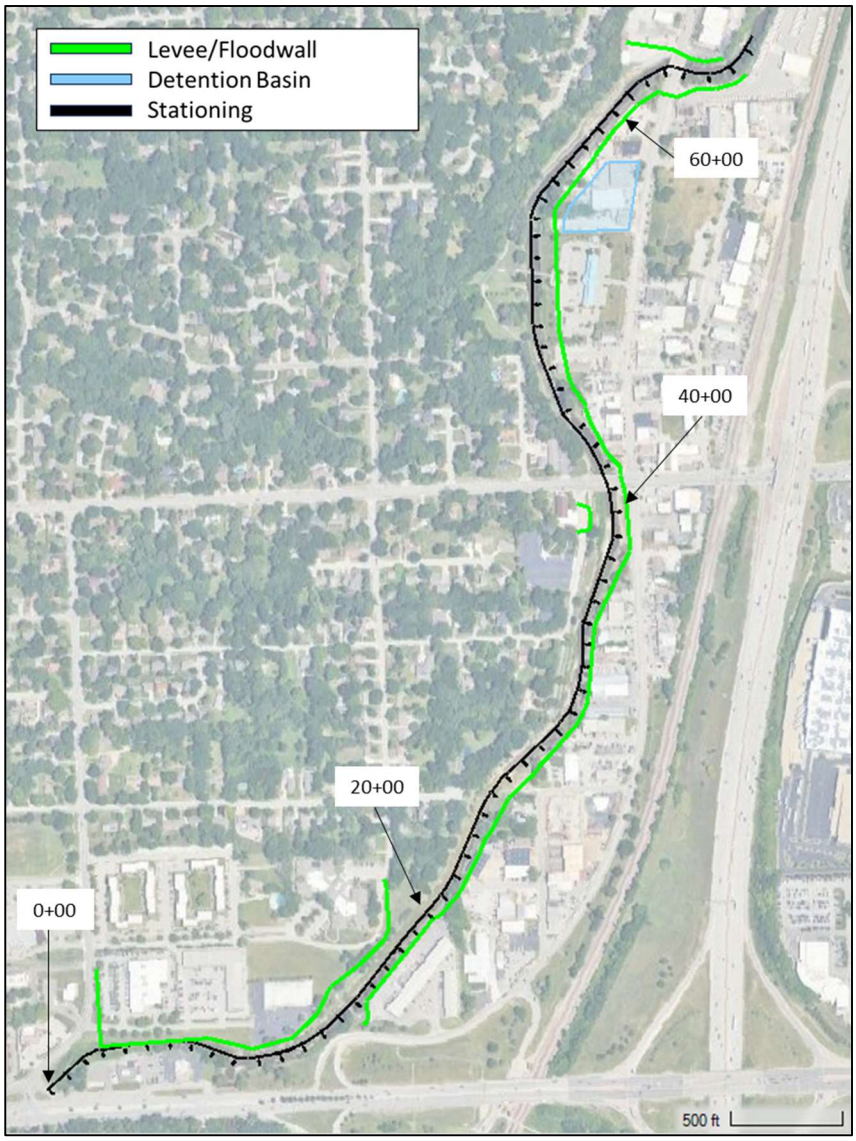
5.0 INTERIOR DRAINAGE

This project includes improvements to interior drainage infrastructure. The areas of specific improvements are provided below:

- Drainage Structures
    - Left Bank—Station (Sta.) 3+00 to 20+00, 39+00 to 40+50, and 62+00 to 66+00
    - Right Bank—Sta. 14+50 to 66+25
- Detention Basin—Sta. 54+00.

The proposed levee alignment and detention basin are displayed in Figure 5.1.

Figure 5.1. Project Features and Stationing



5.1 Design Methodology

This section addresses the general description of the design methodology. This section provides standards, criteria, and available data.

5.1.1 Frequency and Criteria

Engineering Manual (EM) 1110-2-1413, *Hydrologic Analysis of Interior Areas*, dated 24 August 2018, EM 1110-2-1415, *Hydrologic Frequency Analysis*, dated 5 March 1993, and EM 1110-2-2902, *Conduits Pipes and Culverts Associated with Dams and Levee Systems,* dated 31 December 2020 represent the applicable design criteria for the interior drainage analysis.

American Public Works Administration Specification Section 5600 (2011 Version), *Storm Drainage Systems & Facilities* (APWA), is the local design criteria for the Kansas City metropolitan area, including both Johnson County and the City of Merriam in Kansas. APWA states that property not reserved or designed for conveying storm water shall have a system to convey the 10-year (10% AEP) rainfall event when the total drainage area is two acres or more.

For modifications to existing storm drainage crossings under the proposed levee/floodwall, the proposed drainage crossings were sized to convey flows equal to or greater than the capacity of the existing system. The proposed drainage crossings were sized to minimize the induced impacts for a 1% AEP rainfall event where possible. These proposed drainage structures were also sized to a minimum of 24 inches as a part of inspection best practices.

Due to the scope and size of this project, the APWA criteria for detention basin sizing is not applicable. APWA requires the detention basin to be sized for the 1% AEP, 24-hour design storm for development projects. A development project is defined by APWA as, “Any activity, including subdivision, that alters the surface of the land to create additional impervious surfaces, including, but not limited to, pavement, buildings, and structures.” This is not applicable to this scope. The goal of the interior drainage is to focus on what best serves the site and has the least flood impact, while being cost effective. The detention basin storage will be determined by the 10% AEP, 24-hour precipitation event to match the current storm sewer infrastructure in place. The non-federal sponsor concurs with this assessment.

All elevations in this chapter are referenced to the North American Vertical Datum of 1988 (NAVD88) in feet. North American Datum (NAD) 1983 State Plane Coordinate System (SPCS) for Kansas North was used as the spatial datum.

5.1.2 Enclosed Pipe Systems

Design guidance for pipe velocities, depths of cover, and invert offsets were obtained from the APWA standard. The guidance for closed pipe systems was as follows:

- Velocity within the system shall be between 3 and 20 feet per second.
- Minimum depth of cover shall be 18 inches.
- Pipe crowns entering a drainage structure shall be at or above the crown of the pipe exiting from the structure and provide a minimum fall of the invert in the structure of 0.2 feet.

Manning’s n values were determined from the HEC-RAS Hydraulic Reference Manual – Table 6-1 Manning's "n" for Closed Conduits Flowing Partly Full as shown in Table 5.4.

The diameter and slope of new pipes was selected to meet flow and velocity targets for that span’s cumulative flow rate and to minimize diameter changes along the longitudinal run.

5.1.3 Construction of Drainage Structures

Current design criteria for Turkey Creek includes installation of outfall structures near the normal flow line of the creek with a flap gate. Storm system crossings of levees and floodwalls will not have double closures as required by EM 1110-2-2705. This is because the risk to life safety is negligible and the likelihood of a flap gate getting pinned fully open is low as identified in the Semi Quantitative Risk Assessment (SQRA). Even if a flap gate is pinned open, the backflow that gets through is not substantial. These crossings will not have the landside manholes and closures and will only have passive closure devices at the outfall to Turkey Creek as documented in the Design Guidance Deviation for Secondary Closure for Storm Drainage Pipes Memorandum. Life safety and backflow sensitivity testing are documented in the 2025 SQRA.

Existing storm water pipes through the levee or floodwall alignment that are not a part of the design are to be removed or abandoned and grout filled. Installation of a headwall and flap gates at the existing triple 7-foot by 7-foot reinforced concrete box (RCB) drainage structure at Sta. 38+60 is included as part of the drainage structure design.

These design criteria are maintained to ensure protection of the leveed area is passive, as Turkey Creek is extremely flashy, and the sponsor cannot ensure personnel will be on site in time to close gate wells at all times of the day. See Figure 5.2 for the intensity of historic precipitation events and Section 5.3 for more detailed information on historic events.

5.1.4 Data Available

Bridges, culverts, and channel cross-sections were taken in the field by Stockwell Engineers Inc. between May and July 2023. All structures along the study streams were surveyed and incorporated into the models as 2D connections.

LiDAR data was provided by Johnson County, Kansas, through the Automated Information Mapping System (AIMS) for Turkey Creek and Brush Creek (2-foot resolution). The LiDAR acquired from AIMS was collected in 2020. For the portion of the Turkey Creek watershed located in Wyandotte County, Kansas, supplemental LiDAR was downloaded from Kansas' Data Access & Support Center (DASC) at 1-meter resolution. The LiDAR acquired from DASC was collected in 2018. The DASC LiDAR was reprocessed to match the resolution of the Johnson County LiDAR and were mosaicked together. LiDAR was used to obtain ground elevations for areas outside the survey limits and to draw approximate drainage areas.

The City of Merriam, Kansas, provided a shapefile of existing stormwater pipes for the approximate storm sewer location for the city. AIMS was used to fill in any gaps in the existing pipe network.

The high-water mark collection results for the July 17th, 2025, precipitation event are stored in Appendix E.1.

Structural flooding elevations (Table 5.11) were aggregated between multiple sources. These included a survey from Stockwell Engineers Inc. which contained elevations for nine structures of interest. The rest of the flooding elevations were estimated from AIMS and the previously mentioned LiDAR.

5.1.5 Rainfall Depth Analysis

Johnson County, Kansas, funded Dr. Bruce McEnroe, a technical expert on the hydrology within Johnson County, to evaluate the appropriate precipitation and temporal distribution for the watershed studies within the county. The Rainfall for Flood Studies: Indian and Tomahawk Creeks Report (Appendix M.1), completed in November 2023, also evaluated the appropriate

rainfall distribution for the flood frequency watershed analysis. Based on Dr. McEnroe's evaluation, a 12-hour nested hyetograph with a 3-hour peak was determined as an appropriate temporal distribution for Johnson County, Kansas.

Johnson County concluded that a single rainfall depth derived from NOAA Atlas 14 be applied to all watershed studies in the county. Those depths were derived from KDOT's rainfall tables, which are averaged by county and summarized in Table 5.1. These annual maximum rainfall depths range from 0.03 inches higher for the 50% AEP event to 0.16 inches higher for the 0.2% AEP event when compared to Atlas 14 depths.

Table 5.1. 12-hour Duration Rainfall Depths for Johnson County, Kansas.

	Annual Exceedance Probability Event						
	50%	10%	4%	2%	1%	1%+*	0.2%
12-hour Rainfall Depth (inches)	3.17	4.74	5.82	6.71	7.65	8.56	10.04

*1%+ AEP is the high end of the 90 percent confidence interval for the 0.01 AEP event.

A hydrologic analysis for the Turkey Creek watershed was completed using HEC-1 in May 2005. These HEC-1 outputs provide 24-hour duration rainfall events. The HEC-1 output files provide the cumulative rainfall percentage and the total precipitation over the 24-hour period. Based on those provided inputs, rainfall depths can be determined as seen in Table 5.2.

Table 5.2. 24-hour Duration Rainfall Depths for Johnson County, Kansas

	Annual Exceedance Probability Event						
	50%	10%	4%	2%	1%	0.5%	0.2%
24-hour Rainfall Depth (inches)	3.67	5.52	6.76	7.76	8.8	9.9	11.4

The HEC-1 24-hour duration rainfall depths was used for this analysis. This was to better meet standards for the detention basin sizing and match the analysis in Part 04–Hydrology and Hydraulics.

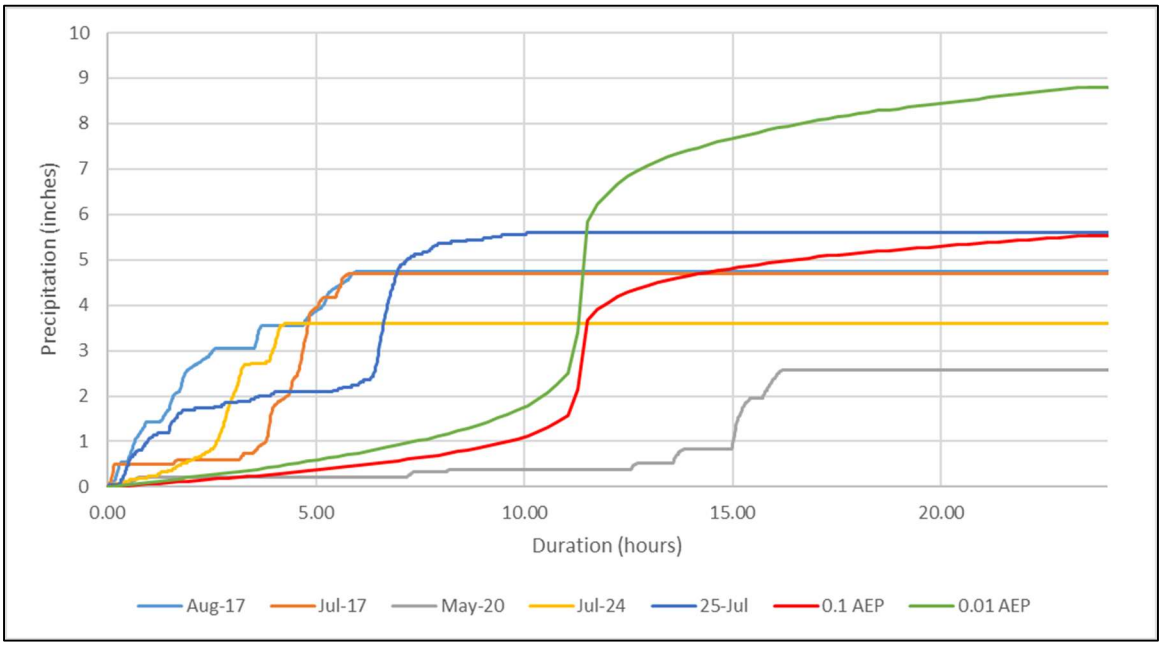
Real precipitation events were also included in the interior drainage hydraulic modelling. These were used to provide historic examples of how long it takes for the water to rise out of existing banks as well as more comparisons between existing and proposed conditions. These include events in July 2017, August 2017, May 2020, July 2024, and July 2025 and can be seen in Figure 5.2. These events cover a range of 2-to-50-year return periods as shown in Table 5.3. These events were chosen due to their precipitation intensity and their recency. The City of Overland Park's StormWatch gages were used to develop the precipitation input for these events, utilizing the StormWatch precipitation gages and incremental rainfall for periods of interest.

Table 5.3. Historic Storm Event Information

Storm Event	**Total Precipitation (in)**	**Precipitation Duration (hrs)**	**Return period (years)**

July 2017	4.7	5.8	10 to 25
August 2017	4.8	6.6	10 to 25
May 2020	2.6	3.7	2 to 5
July 2024	3.6	4.2	5 to 10
July 2025	5.6	9.8	25 to 50

Figure 5.2. Cumulative Precipitation for Theoretical and Real Precipitation Events – TU03 Gage.



5.2 Interior Drainage Hydraulic Modeling

This section addresses the general description of the existing and proposed conditions and their respective hydraulic modeling. Hydrologic Engineering Center River Analysis Software (HEC-RAS) version 6.7 beta 5 was used for this analysis.

The hydrologic calculations were developed directly in the HEC-RAS model using a rain-on-grid, 2D approach. For more information on hydrologic analysis, reference Appendix E.7.

The subbasin modeling was developed using the Hydrologic Engineering Center Hydrologic Modeling System (HEC-HMS) version 4.11. The HEC-HMS model included the complete watershed contributing to the upper portion of Turkey Creek. LiDAR data, referenced in section

5.1.4, provided the existing terrain of the watershed. Break points were placed in HEC-HMS to represent gravity drain locations. Using HEC-HMS, streams were identified and subbasins were initially delineated. Subbasins that flowed into the reach of interest were selected and exported to the HEC-RAS model. This model was used exclusively for subbasin delineation and was only interested in the surface interactions and did not account for subbasin delineation with respect to pipe connectivity between watersheds.

The Stantec Hydrologic Engineering Center River Analysis System (HEC-RAS) model was pulled into version 6.7 beta 5. The rain-on-grid 2D component used precipitation data to determine the flows and water surface elevations for the Turkey Creek watershed. Subbasin numbering corresponds to the drainage structure number. Subbasins were adjusted using HEC-RAS particle tracing and existing stormwater drainage. Figure 5.3 shows the subbasins within the entire Upper Turkey Creek watershed and Figure 5.4 show the subbasins within the project area. The Upper Turkey Creek watershed drains approximately 7,850 acres to the downstream end of the project.

Due to the flashy nature of Turkey Creek, the modeling strategy sought to keep the coincident timing of the interior drainage systems tethered to the stages in Turkey Creek. Therefore, Stantec's rain-on-grid, 2D model was selected as the base existing conditions model. The rain-on-grid in Stantec's model applies rainfall across the entire Upper Turkey Creek watershed (pink polygon in Figure 5.3). For theoretical annual exceedance probability events, one precipitation hyetograph is applied for the entire watershed. For historical events, a group of gage locations used the Thiessen polygon method to implement recorded precipitation hyetographs across the watershed. See Appendix M.2 for hyetograph data.

Stantec's model includes major bridges and culverts. Stantec's model does not include a modeled stormwater system. See Appendix E.7 for more information regarding Stantec's base model.

The hydraulic calculations were developed directly in the HEC-RAS model. The base of the hydraulic model was the HEC-RAS model provided by Stantec Inc. For more information on the base hydraulic model, reference Stantec's July 2024 Turkey Creek and Brush Creek 2D Watershed Hydrologic and Hydraulics Report. Further hydraulic developments were made in the Stantec Base model.

The bridge modeling methods in the interior design hydraulic model match the bridges described in Part 04 – Hydrology and Hydraulics.

Circular drainage structures were modelled as pipe networks with no negative flow flaps and other shapes were modeled as 2D connections featuring culverts, with no negative flow flaps and using the normal 2D Equation Domain, so weir coefficients are not impactful.

Figure 5.3 Upper Turkey Creek Watershed

Figure 5.4. Turkey Creek Interior Drainage Project Area

5.2.1 Calibration & Validation of Base Model

Stantec's rain-on-grid, 2D model was calibrated using 2 historic storm events in the watershed, August 22, 2017, and May 28, 2020. The City of Overland Park's StormWatch gages were used to develop the precipitation input for the calibration events, utilizing the StormWatch precipitation gages and incremental rainfall for periods of interest. These gages were also used to calibrate the model based on the recorded stages during the historic flood events throughout the watershed. See the locations used for calibration in Figure 5.5.

Figure 5.5. Stormwater Gage Locations for Calibration.

The final calibration parameters include Manning's n calibration regions along Turkey Creek to vary the roughness values between the deeper flow in the channel and the shallow flow in the uplands. The final abstraction ratio for the basin was set to 0.1. The base curve numbers were derived using the NRCS TR-55 method and not altered during calibration. Channel roughness along Turkey Creek ranged from 0.025 to 0.035 with the lower n values along the stretch of Turkey Creek along Johnson Drive and Antioch Road. No roughness modifications were made from the Stantec rain on grid model. The upland n values were set to represent shallow overland flow Manning's n values. Table 5.4 summarizes the calibrated Manning's n- values by land cover.

Table 5.4. Calibrated Manning's n-value by Land Cover.

Description	Base n-value	Calibrated Floodplain n-value	Calibrated Upland n-value
Trees	0.085	0.060	0.140
Natural Channel	0.035	0.035	0.035
Concrete Channel	0.015	0.015	0.015
Pavement	0.020	0.015	0.020
Grass	0.030	0.030	0.140
Buildings	1	1	1
Barren Land	0.025	0.025	0.045
Open Water	0.025	0.025	0.030

The final calibrated results from the August 2017 and May 2020 historical events are summarized in Table 5.5 and Table 5.6. The absolute average of the difference in WSE between the calibrated model and the observed WSE is 1.1 and 1.0 feet for the August 2017 and May 2020 events respectfully. The average of the difference in WSE between the calibrated model and the observed WSE is 0.95 and -0.75 feet for the August 2017 and May 2020 events respectfully.

Table 5.5. August 2017 Calibration Results.

Gage	Calibrated Model WSE Peak (ft)	Observed Peak WSE (ft)	Difference (ft)
TU2	954.5	953.2	1.3
TU3	937.9	937.5	0.4
TU4	907	904.5	2.5
TU6	884.4	883	1.4

Gage	Calibrated Model WSE Peak (ft)	Observed Peak WSE (ft)	Difference (ft)
TU7	859.8	860.3	-0.5
TU8	841.6	841	0.6
		Absolute Average	1.1
		Average	0.95

Table 5.6. May 2020 Calibration Results.

Gage	Calibrated Model WSE Peak (ft)	Observed Peak WSE (ft)	Difference (ft)
TU2	953.9	953.7	0.2
TU3	935.6	937.3	-1.7
TU4	904.8	904.2	0.6
TU6	882.6	882.7	-0.1
TU7	857.9	860	-2.1
TU8	839.5	840.9	-1.4
		Absolute Average	1.0
		Average	-0.75

To validate this calibration, high water marks were collected for the July 17th, 2025, precipitation event. See Appendix E.1 for documentation of the high-water mark collection. Validation results from the July 2025 historic event are summarized in Table 5.7. The absolute average of the difference in WSE between the calibrated model and the observed WSE is 0.8 feet, and the average is -0.37 feet. These values falls within the accepted ranges of the prior calibrated events, so no further calibration was required.

Table 5.7. July 2025 Validation Results.

		Average	-0.37

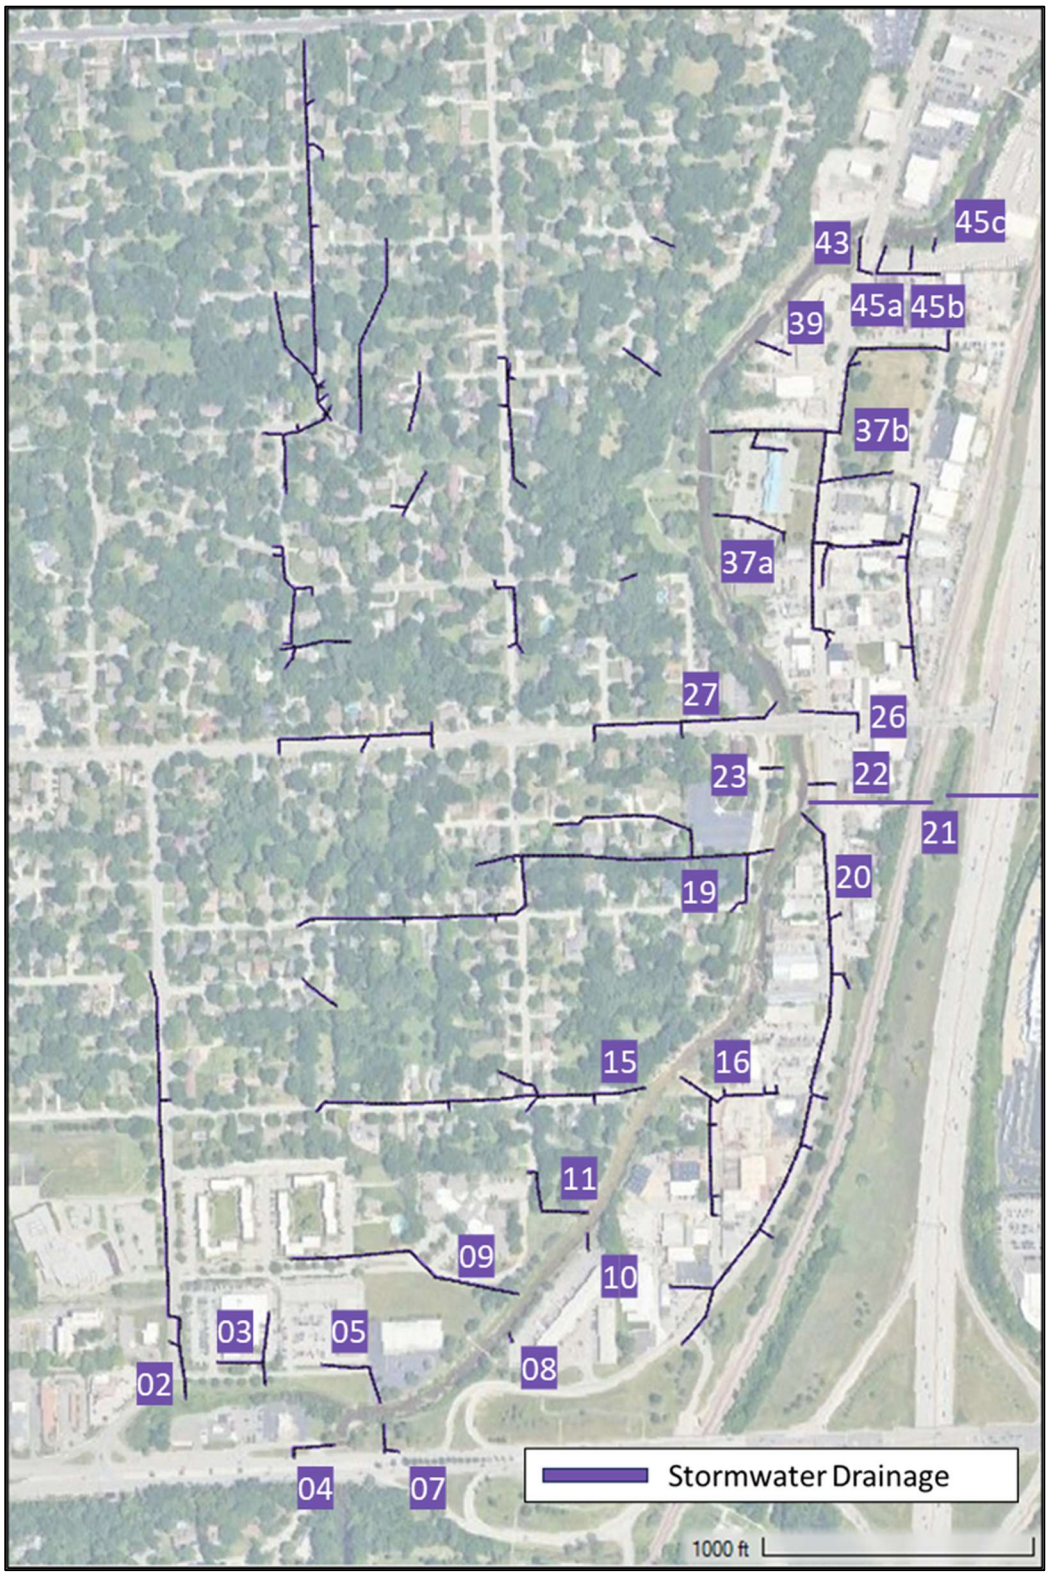
5.2.2 Existing Conditions Hydraulic Model

Stantec's base model provided the basis for the existing conditions geometry for the Turkey Creek watershed. No levee or floodwall currently exists in the Turkey Creek watershed. There is an existing depression with approximate dimensions of 100 feet by 300 feet, a maximum depth of 3 feet, and an approximate average depth of 2 feet on the right bank north of Merriam marketplace where the detention basin will be placed as part of the proposed design.

The existing conditions geometry includes the addition of the existing stormwater system within the project reach as shown in Figure 5.6. These existing structures are based on the previously mentioned shapefile of existing stormwater pipes, as well as AIMS data discussed in Section 5.1.4. See Appendix M.3 for full existing conditions pipe network data.

This geometry was used as an existing conditions baseline for hydraulic properties, including water surface elevation and depth.

Figure 5.6. Turkey Creek Existing Conditions Storm Pipe Network.

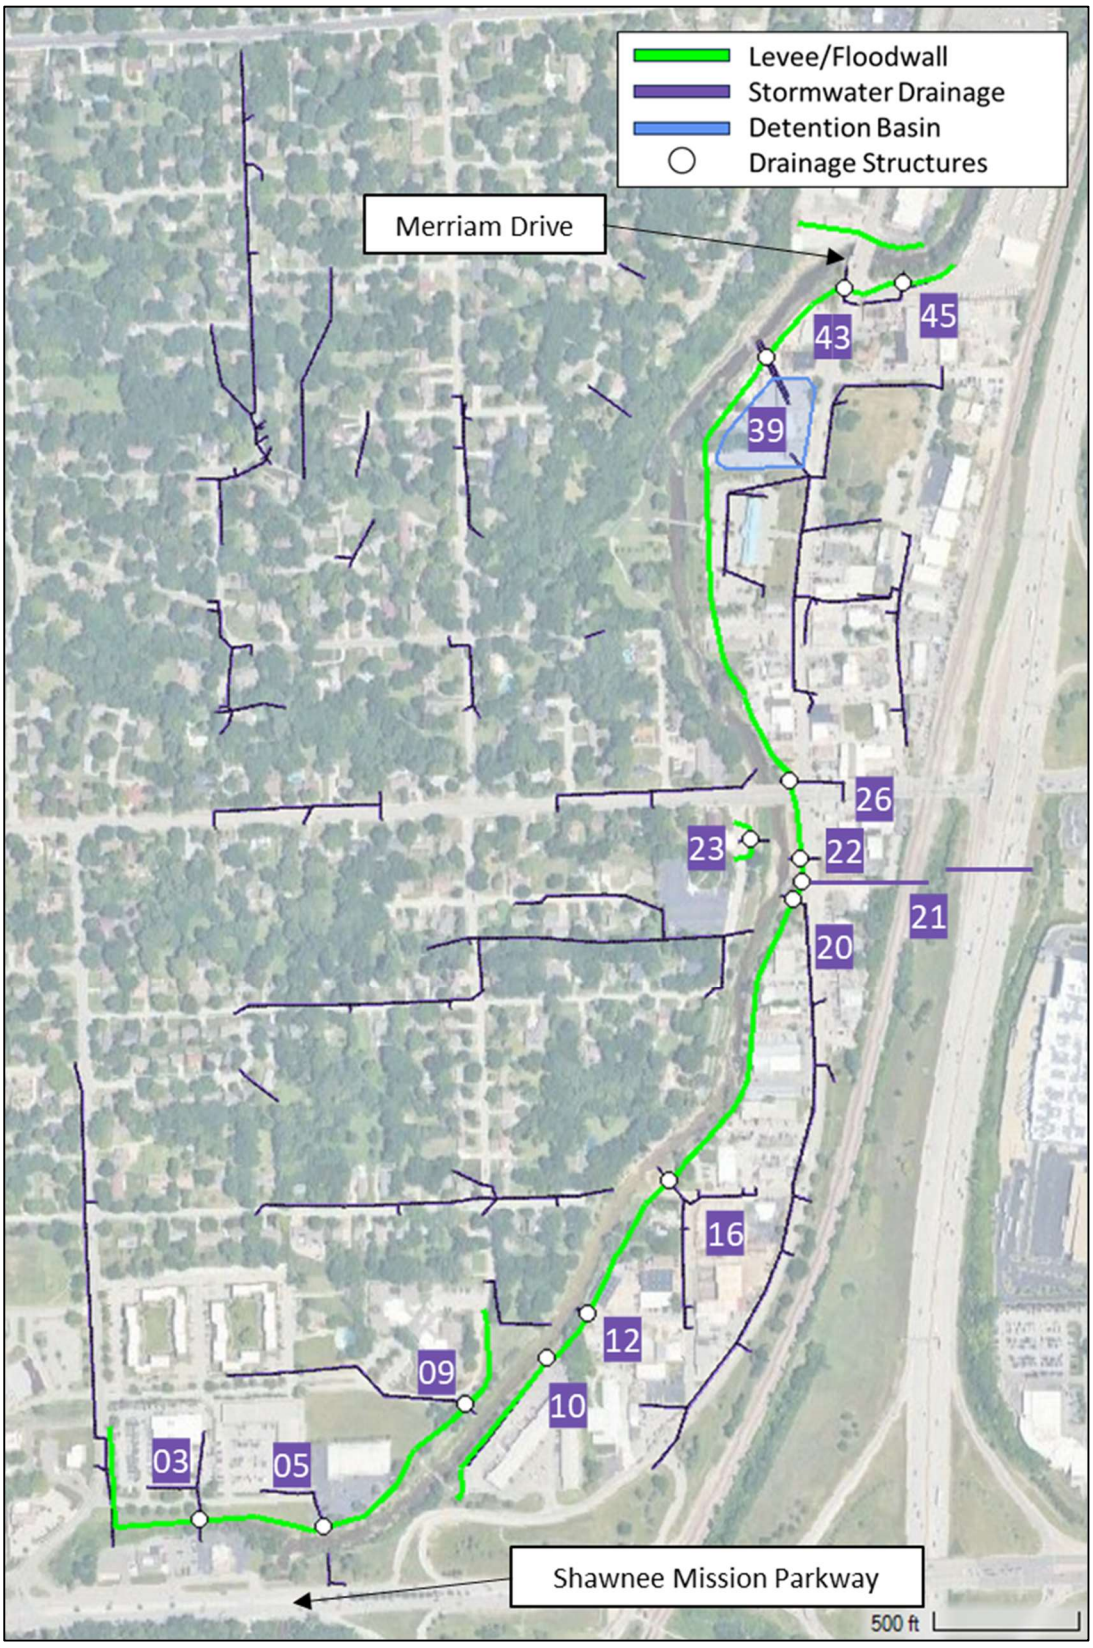


5.2.3 Proposed Conditions Hydraulic Model

The proposed work consists of construction of levee and floodwall sections, interior drainage structure additions or alterations, and a dry detention basin. This work will be completed along Turkey Creek in the City of Merriam, Kansas, from Shawnee Mission Parkway on the south (upstream) end to Merriam Drive just north of West 57th Street on the north (downstream) end.

The current recommended plan has identified a total of 14 locations where stormwater drainage lines would cross under the proposed levee or floodwall. Table 5.8 provides a summary of proposed storm drainage structures and Figure 5.7 provides locations of the drainage structures in the project area. See Appendix M.3 for full proposed conditions pipe network data.

Figure 5.7. Upper Turkey Creek Proposed Conditions Storm Pipe Network.



5.2.4 Interior Drainage Structure Design

The interior drainage structures consists of 24-inch to 60-inch RCP, as well as the existing triple 7-foot-by-7-foot box culverts, designed to drain using open-channel gravity flow. Table 5.8 contains information regarding the hydraulic model drainage system pipe design. All drainage structure pipes have a flow flap blocking all backflow from Turkey Creek into the levee interior. Pipe design was completed to meet requirements stated in Section 5.1.2 and to minimize induced impacts of the 1% AEP rainfall event on the interior area. Pipe design was limited to the conduits crossing under the levee or floodwall or connection of two drainage systems into one to reduce the number of conduits under the levee or floodwall. All structures meet the specified design criteria from section 5.1.2 and meet the goal to minimize induced impacts to the extent feasible. All conduits under the levee and floodwall alignment have a Manning's n value of 0.015 to represent reinforced concrete pipes and entrance and exit loss coefficients of 0.5 for square cut. System calculations showing pipe sizes, invert elevations, slopes, and maximum velocities are included in Appendix M.4

Table 5.8. Drainage Structure Pipe Design.

Structure Number	HEC-RAS Conduit Name	Outlet Pipe Diameter (feet)	Landside Invert Elevation (feet)	Riverside Invert Elevation (feet)	Length (feet)	Slope*
ST-03	ST-03 1	2	927.25	922.01	123.18	4.25%

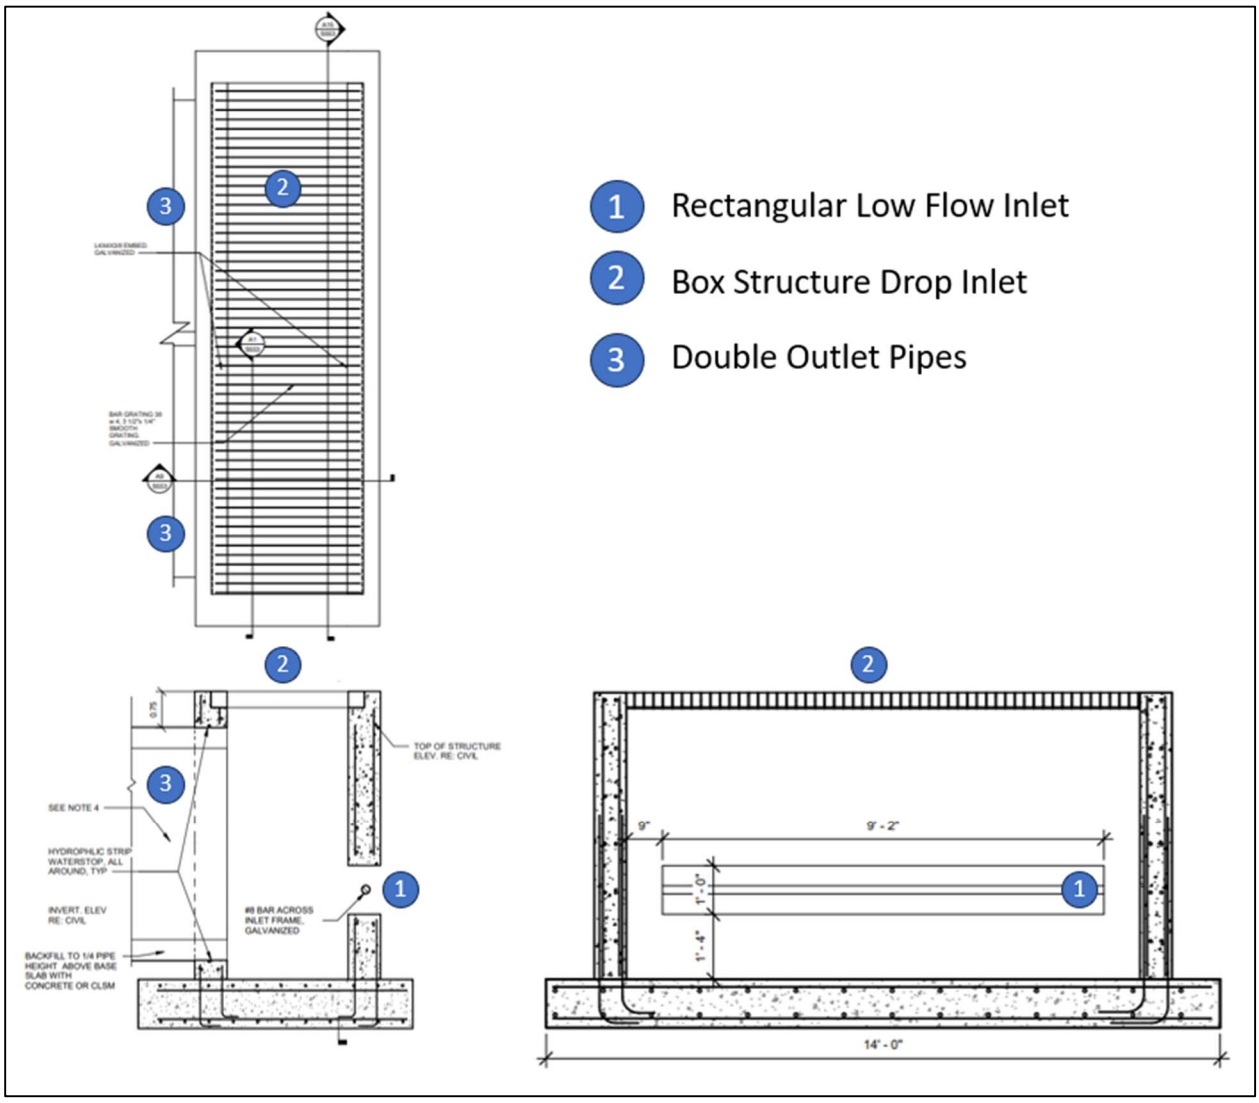
Structure Number	HEC-RAS Conduit Name	Outlet Pipe Diameter (feet)	Landside Invert Elevation (feet)	Riverside Invert Elevation (feet)	Length (feet)	Slope*
ST-43	ST-43 1	2	895	889.65	118.4	4.52%
ST-45	ST-45 1	2	893.77	890.79	61.34	4.86%

*Pipe lengths and slopes in this table reflect information from hydraulic modelling, not civil design. Hydraulic pipe lengths should be near the value provided by civil, slopes may vary due to differences in pipe length. Limitations in hydraulic modelling of pipe networks may also lead to some deviations from civil design values. These deviations are not expected to significantly impact results.

5.2.5 Detention Basin Proposed Design

An 11.0-acre-foot grassed detention basin will be constructed, with a footprint of approximately 72,300 square feet, an invert elevation of 893.75 feet, and a maximum depth of 12.25 feet. The detention basin drainage outlet structure (ST-39) is described as follows. A 12-foot X 5.5-foot box structure drop inlet at 897.75 feet with an open grate, a 1 foot X 9 foot rectangular low flow inlet at 893.75 feet, connected to two 48” diameter RCP outflow pipes with flap gates. See Figure 5.8 for structural drawings of the detention basin drainage outlet structure.

Figure 5.8. Detention Basin Drainage Outlet Structure.



This detention basin is proposed to collect stormwater runoff originating from locations landward of the levees and floodwall from the northern right bank area of the project. The structure is located north of Merriam Marketplace, shown in Figure 5.4.

This detention basin volume is based off of the ability to store the 10% AEP rainfall event below the invert elevation of the contributing storm water system. A 10% AEP rainfall event was selected for design instead of the 1% AEP rainfall event required in APWA due to detention basin size limitations and inapplicability of the site development definition. The change in design criteria was made with sponsor concurrence and is further explained in Section 5.1.1. This event was determined to have 5.52 inches of excess precipitation from the 2005 HEC-1 study as discussed in Section 5.1.5. To determine the footprint of the detention basin, a polygon was created with sides located 20 feet within the boundaries of the property lines and levee toe to provide the maximum footprint, per APWA Section 5608.2, and as shown in Figure 5.9. Side slopes of 3:1 (H:V) were implemented on the non-levee sides and a side slope of 5:1 was implemented on the levee side, per APWA 5600 Section 5608.5.A.4. A slope of 1% runs along the floor of the detention basin, leading to a low point in the northwestern corner at 893.75 feet,

where the outlet is located. The existing storm water system was altered to have one outfall into the detention basin on the southeast corner. This allowed for the highest possible outfall elevation, in turn providing the highest possible bottom of the basin. The hydraulic components can be seen in Figure 5.10. The detention basin was designed to store the 10% AEP event under gravity flow conditions, which lead to a storage capacity of 2.74 acre-feet of water below the storm water entrance invert (896.6 feet). The 10% AEP detention basin sizing was deemed acceptable by the sponsor.

Figure 5.9. Proposed Detention Basin Location.

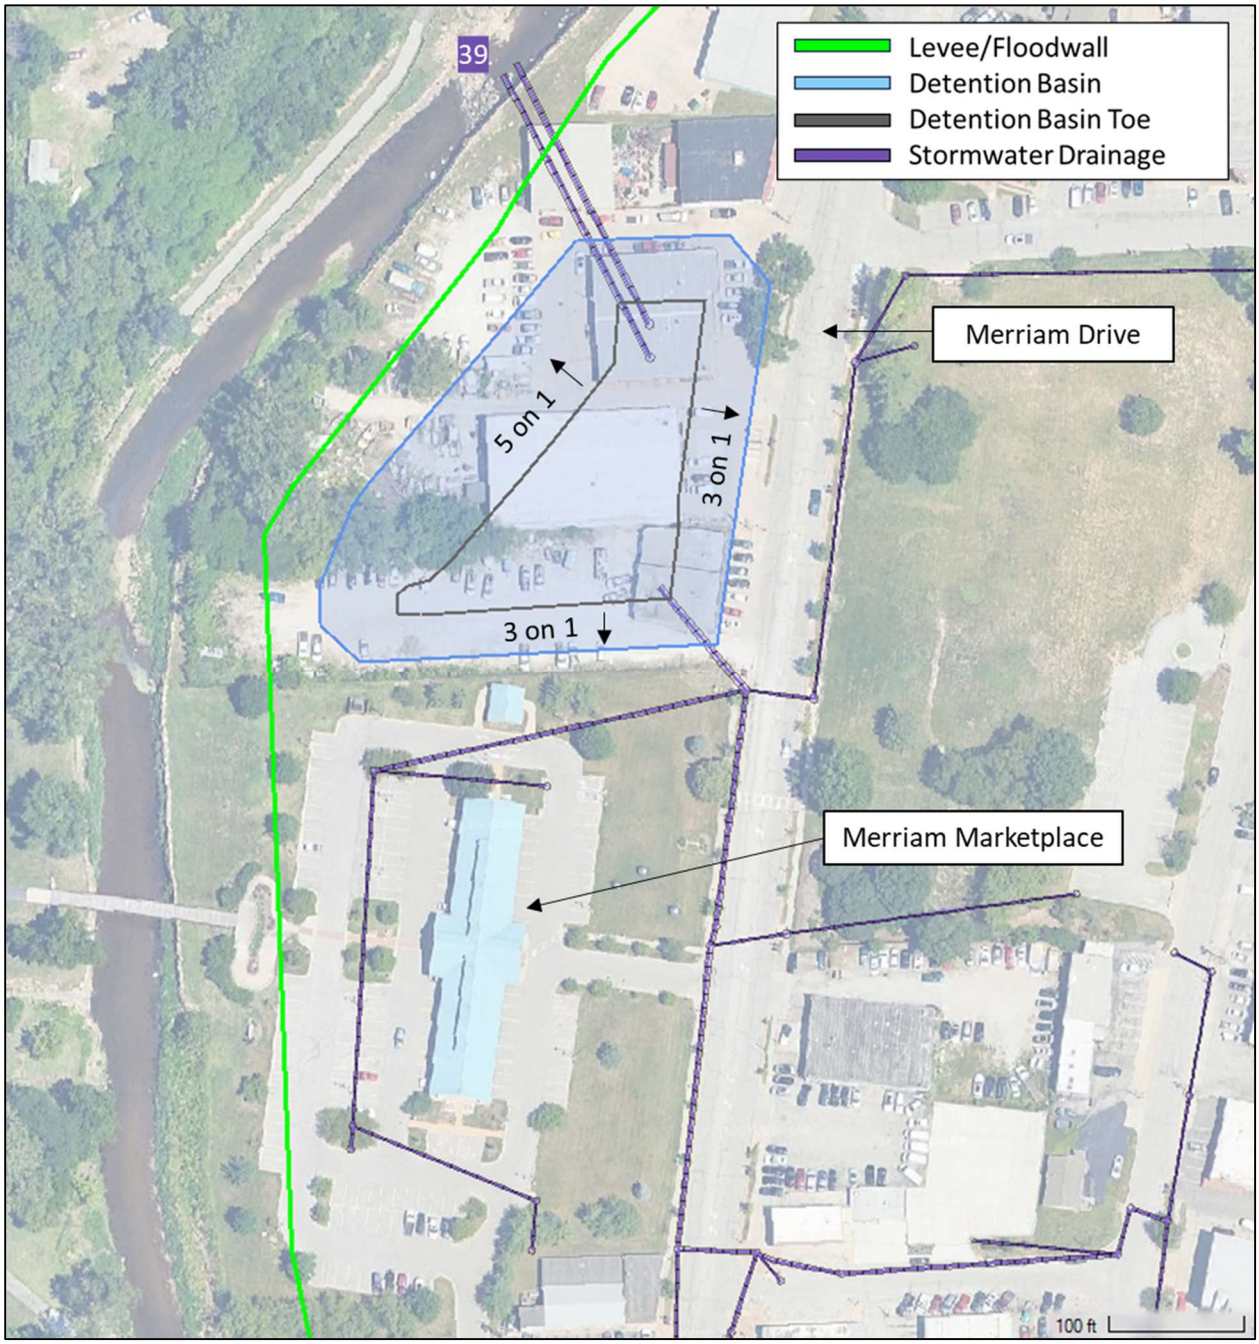


Figure 5.10. Detention Basin Implementation in the Hydraulic Model.

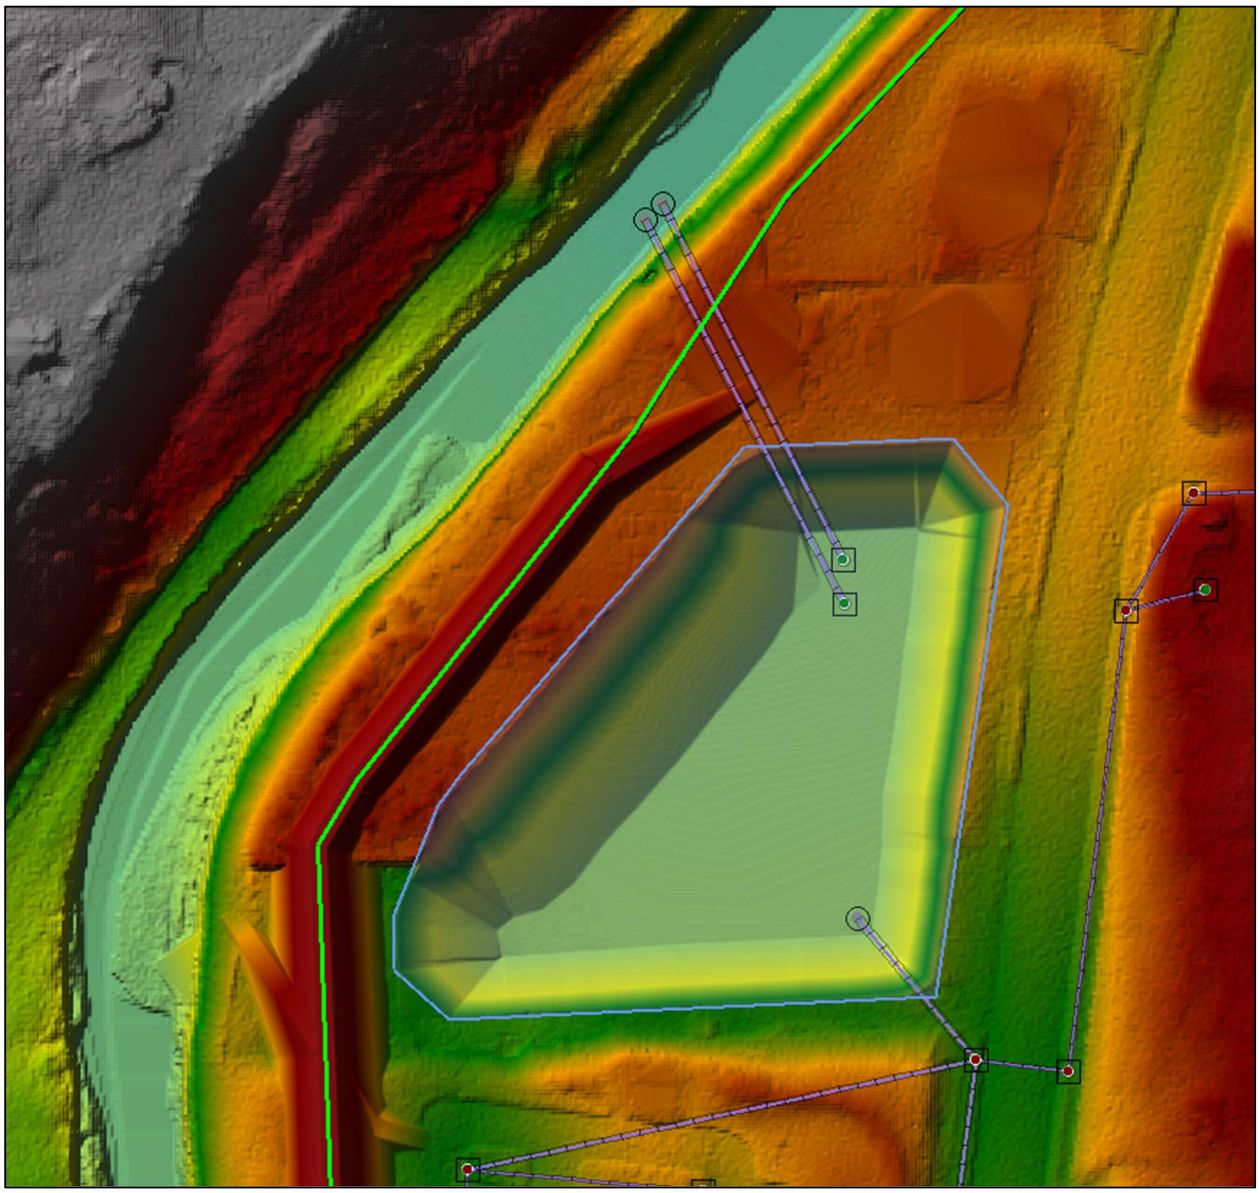

5.3 Coincident Frequency Analysis

A coincident frequency analysis was ruled out during the SQRA due to the small watershed size as documented in Section 4.4.2 of the SQRA. It was determined that since the contributing drainage area upstream of the project was aligned south to north and approximately 10.57 square miles, that the typical west to east storm pattern will hit both the contributing area and the interior area. Since the same system hits both Turkey Creek and the interior, it is assumed the same frequency event occurs on both the creek and the interior drainage.

5.4 Rate of Rise Analysis

A group of notable historic storm events with gridded precipitation was reviewed for rate of rise characteristics: July 26-28, 2017, August 21-23, 2017, May 27-29, 2020, July 01, 2024, and July 17, 2025. The historic storm events were used to determine realistic maximum hourly rate of rise (Table 5.9) and warning time (Table 5.10). Warning time is defined as the time from the first rainfall to the time when the channel WSE causes the drainage structure flap gates to close.

Table 5.9. Historic Storm Event Maximum Hourly Rate of Rise (ft/hr).

Storm Event	ST-03	ST-05	ST-09	ST-10	ST-12	ST-16	ST-20	ST-21	ST-22	ST-23	ST-26	ST-39	ST-43	ST-45
July 2017	10.0	9.0	10.2	8.2	7.4	9.6	11.5	11.6	11.5	11.5	11.8	12.8	12.3	11.0
August 2017	5.7	5.0	6.0	8.4	4.3	5.1	7.7	7.8	7.8	7.6	8.4	9.0	8.9	8.1
May 2020	3.0	3.8	4.5	7.4	4.3	3.4	6.1	6.1	6.1	6.2	6.7	6.2	5.8	5.2
July 2024	8.3	8.0	9.6	6.8	6.4	7.1	11.6	11.6	11.7	11.9	12.6	12.7	12.2	11.0
July 2025	14.2	12.9	14.4	9.3	10.4	13.0	17.5	17.5	17.4	17.4	18.0	19.4	18.7	16.9

EM 1110-2-2902, Conduits Pipes and Culverts Associated with Dams and Levee Systems lists the closure type requirements for different flood rise conditions. The flood rise condition for the project was considered fast since there was less than 12 hours of warning time as shown in Table 5.10. This requires the use of passive closure structures.

Table 5.10. Historic Storm Event Warning Time (hrs).

Storm Event	ST-05	ST-10	ST-12	ST-16	ST-20	ST-21	ST-22	ST-26	ST-39
July 2017	4.57	4.53	4.43	4.45	-	-	4.5	4.5	4.42
August 2017	-	-	-	-	-	-	-	-	3.85
May 2020	-	-	-	-	-	-	-	-	6.47
July 2024	-	-	-	-	-	-	-	-	0.7
July 2025	-	-	-	-	1.58	0.78	1.57	1.57	0.75

*Drainage structures not included in this table do not reach closure conditions, and in turn do not register a warning time across all historic events.

5.5 Analysis of Existing and Proposed Conditions with Theoretical Storm Events

Table 5.11 shows structural flooding and subbasin drainage area. Structural flooding is defined as the WSE required for the first building in the subbasin to be touched by water. These structural flooding elevations were determined using survey data where possible and a combination of AIMS and LiDAR data where survey data was not available, as referenced in Section 5.1.4. These structural flooding elevations were used to evaluate critical subbasins. The subbasin drainage areas can be seen in plan view in Figure 5.4. The drainage structure numbering system matches the subbasin numbering system throughout this report.

Table 5.11. Subbasin Properties.

Subbasin Number	Structural Flooding Elevations (feet)	Drainage Area (acres)
ST-03	936.0	3.8
ST-05	933.4	3.7
ST-09	932.4	16.3
ST-10	929.8	5.4
ST-12	923.0	2.2
ST-16	917.0	5.7
ST-20	912.0	22.9
ST-21	926.0	434.2
ST-22	912.0	2.2
ST-23	916.1	1.2
ST-26	910.0	1.3
ST-39	903.9	26.2
ST-43	909.5	1.4
ST-45	908.0	4.8

The two scenarios analyzed for the existing and proposed conditions for interior drainage are the 10% AEP, 24-hour rainfall event and 1% AEP, 24-hour rainfall event.

Two specific goals for the proposed design were to ensure the identified conduit size and location were sufficient to convey flow; and (where possible) to not induce increased water surface or structural flooding due to the presence of the levee alignment.

The design team attempted to reduce the peak WSE in all the subbasins so there were no areas with increases in peak WSE. However, due to rapid flap gate closure occurring due to the channel WSE being greater than the interior WSE, any feasible increase in pipe capacity could not solve the problem. An increase in detention capacity would be required to reduce the peak WSE. However, detention options were not feasible on a real estate or cost basis, apart from the location north of Merriam Marketplace. The design team settled on flowage easements to

mitigate the increase in peak WSE. See Section 5.7 for more information on the flowage easement areas.

The data tolerance threshold used for the analysis is 0.1 feet. This includes numbers that round to 0.1 feet, so any value greater than or equal to 0.05 feet meets the data tolerance threshold.

The 10% AEP theoretical event results in Table 5.12 show that five of the fourteen subbasins experience an increase in peak WSE from existing to proposed conditions. However, structural flooding is reduced from four subbasins in the existing conditions to two subbasins with the proposed conditions. See Figure 5.11 for WSE change mapping for the 10% AEP event.

The 1% AEP theoretical event results in Table 5.13 show that three of the fourteen subbasins experience an increase in peak WSE from existing to proposed conditions. However, structural flooding is reduced from nine subbasins in the existing conditions to seven subbasins with the proposed conditions. See Figure 5.12 for WSE change mapping for the 1% AEP event.

Table 5.12. 10% AEP Theoretical Event Results.

5.6 Induced Impacts Mapping

Interior areas were reviewed for induced impacts from peak WSE and duration. Induced impacts from an increase in peak WSE were mitigated where possible by increasing drainage structure capacity or providing detention volume. The remaining areas with increased peak WSE have been deemed either unfeasible or not cost effective to mitigate as part of design.

See Table 5.14 for acreage of induced impacts and Figure 5.13 for the locations of induced impacts in plan view. Induced impact areas were clipped to interior locations where the water surface elevation increases rounded to greater than or equal to 0.1 feet. 0.1 feet was selected because it accurately reflects hydraulic trends without introducing the oscillations at extremely shallow flow. The induced impact areas are comprised of areas of new inundation and increased water surface elevation. The 1% AEP rainfall event was used as the basis for determining the induced impacts. Additionally, impacts from permanent easements are considered in the area determination.

Interior areas with an increase in duration of inundation are captured in the “Duration of Proposed WSE > Existing WSE (hours)” row of Table 5.12 and Table 5.13. These interior areas were determined to provide a relative benefit since the peak inundation WSE is lower than without the project. This relative benefit may counter a potential takings claim.

Table 5.14. Induced Impact Areas.

	ST-09	ST-21a	ST-21b	ST-45	Total

6.0 SUBSURFACE CONDITIONS

This section discusses subsurface investigation and soils laboratory testing and presents subsurface conditions and engineering soil properties for design of the Upper Turkey Creek FRM Project.

6.1 Regional Geology and Geomorphology

This section discusses regional geology near the Upper Turkey Creek FRM Project.

6.1.1 Location

The Turkey Creek Flood Control Project is in the Osage Plains region of the central lowland physiographic region. The generally rolling to level upland has been eroded by Turkey Creek and associated drainageways to create vertical relief of more than 200 feet between the highlands and lowlands of the Turkey Creek channel. Bedrock is exposed in numerous places along the valley walls and in the creek bottom.

6.1.2 Soils

The soils in the Turkey Creek flood plain area are mostly alluvial deposits overlying eroded bedrock surface. The surficial soils generally are comprised of unclassified fill overlying lean clay with layers of clayey gravel found at depth near the bedrock surface. The native alluvial silts and clays belong to Onawa-Haynie Association. The hillside soils in the valley are derived from loess and residual soils of the Knox-Ladoga Association.

The native lean clay deposits (CL) are described as medium to stiff and very stiff consistency materials with liquid limits less than 50 percent and plasticity indices varying from about 13 to 29 percent. Natural moisture contents reported in the exploration data vary from 21 to 29 percent.

There are occasional layers of fat clay deposits within these natural deposits. The fat clays have liquid limits on the order of 52 percent.

Groundwater in the region is generally encountered a few feet above the bedrock surface and fluctuates with ground surface elevation. A relatively thin layer (approximately 4 feet) of clayey gravel immediately above the bedrock is a water bearing layer.

6.1.3 Fills during the Channelization of Turkey Creek

Some fills from the excavation were randomly placed in the study area. Fills from I-35 rock cuts were placed along the left bank and the construction of a low-level levee and railroad yard on the right bank resulted in fills of unclassified materials. The fills have been in place for many years and appear to have consolidated under their own weight.

Some evidence of dumped debris along the right bank and within the flood plain area exists. This dumped debris is generally unsuitable material for use in engineered fills.

6.1.4 Bedrock

Bedrock is exposed in numerous places along the valley walls and in the creek bottom. Bedrock consists of sedimentary bedrock of the Pennsylvanian Age. The rock units along the creek bottom and the valley walls are alternating shales and limestones of the Bronson and Linn subgroups of the Kansas City Group. The high hilltops outside the study area are part of the Zarah subgroup.

The valley walls are eroded into the formations of the Linn subgroup, which are predominantly shales with several limestones. From the top down, the rock units are the Iola Limestone Formation, the Chanute Shale Formation, the Drum Limestone Formation, and the Cherryvale

Formation. The Cherryvale Formation consists of the following members in descending order: Quivira Shale, Westerville Limestone, Wea Shale, Block Limestone, and Fontana Shale. Of particular note is the Westerville Limestone, which in the upper portion is highly variable in lithology, usually consisting of cross-bedded oolitic limestone but may contain varying amounts of shale. The lower 3 to 4 feet is consistently hard, dense limestone. Vertical faces of the Westerville Limestone in this area may not be stable over the long term and the unit may be water bearing.

The valley floor is cut into the formations of the Bronson Subgroup, which are predominately limestones with several shales. From the top down, the rock units are the Dennis Limestone Formation, the Galesburg Shale Formation, and the Swope Limestone Formation. The Dennis Formation consists of the Winterset Limestone Member and the Stark Shale Member. The Swope Limestone Formation consists of the Bethany Falls Limestone Member, the Hushpuckney Shale Member, and the Middle Creek Limestone Member. The upper several feet of the Bethany Falls Limestone consist of a nodular limestone in a shale matrix and is referred to as the *peanut zone*.

The intervening Galesburg Shale Formation consists of Canville limestone (usually absent) and the Galesburg Shale. Differentiating the Galesburg Shale from the overlying Stark Shale is sometimes difficult. The two shales are frequently grouped together as the Stark-Galesburg Shale even though they are from different formations. Review of KDOT profiles for I-35 in the project vicinity indicates a noticeable thickening of this unit to the north, with the appearance of the Canville limestone.

The present Turkey Creek alignment generally flows on or near the top of the bedrock surface. The exposed bedrock in the channel is either shale or Winterset Limestone in the upper reaches while Bethany Falls Limestone is present in the lower reaches near the tunnel entrance.

6.2 Historical Subsurface Investigations

Prior to the most recent subsurface investigation in 2023, several subsurface investigations were completed in the general area, such as for I-35 or for other reaches of Turkey Creek. Two soil borings completed in 2002 are the only borings performed in the current project area for which records have been located. The following subsurface investigations were conducted.

- Corps of Engineers Borings of 1959—Most of these borings were drilled to the top of bedrock or auger refusal. Boring locations and ground elevations are very approximate and were obtained by interpolating between contours of the most recent topographic maps.
- Corps of Engineers Borings of 1989 and 1994–95—These borings included coring of the bedrock. Boring locations and ground elevations were based on actual ground surveys. Limited laboratory tests on typical overburden soils were performed. Standard penetration tests were available for the overburden soils. Groundwater conditions were noted.
- Geologic exploration conducted for the I-35 Highway Project by the Kansas and Missouri Departments of Transportation—Included geologic profiles along the highway and subsurface information at various bridge crossings.
- Feasibility Study (Borings in 2002, Study published in 2015)—The Feasibility Study was conducted over a long time and a large area. As part of the Feasibility Study, an Integrated Environmental Assessment included investigation of 20 square miles of the Upper Turkey Creek watershed. Several pilot borings were conducted along Turkey Creek with the majority placed near the Kansas River located at U.S. 69 Highway and I-

35 and eastward. Two borings drilled in 2002 by USACE, labeled DC-4 and DC-5, were conducted in the current project area.

- These two soil borings revealed mostly silty clay fill and weathered shale to auger refusal on limestone at approximately 13 feet below ground surface. The subsurface investigation continued with rock coring to between 25.9 and 27.6 feet below ground surface.
- Various Terracon projects in the general vicinity.

6.3 2023 USACE Subsurface Investigation

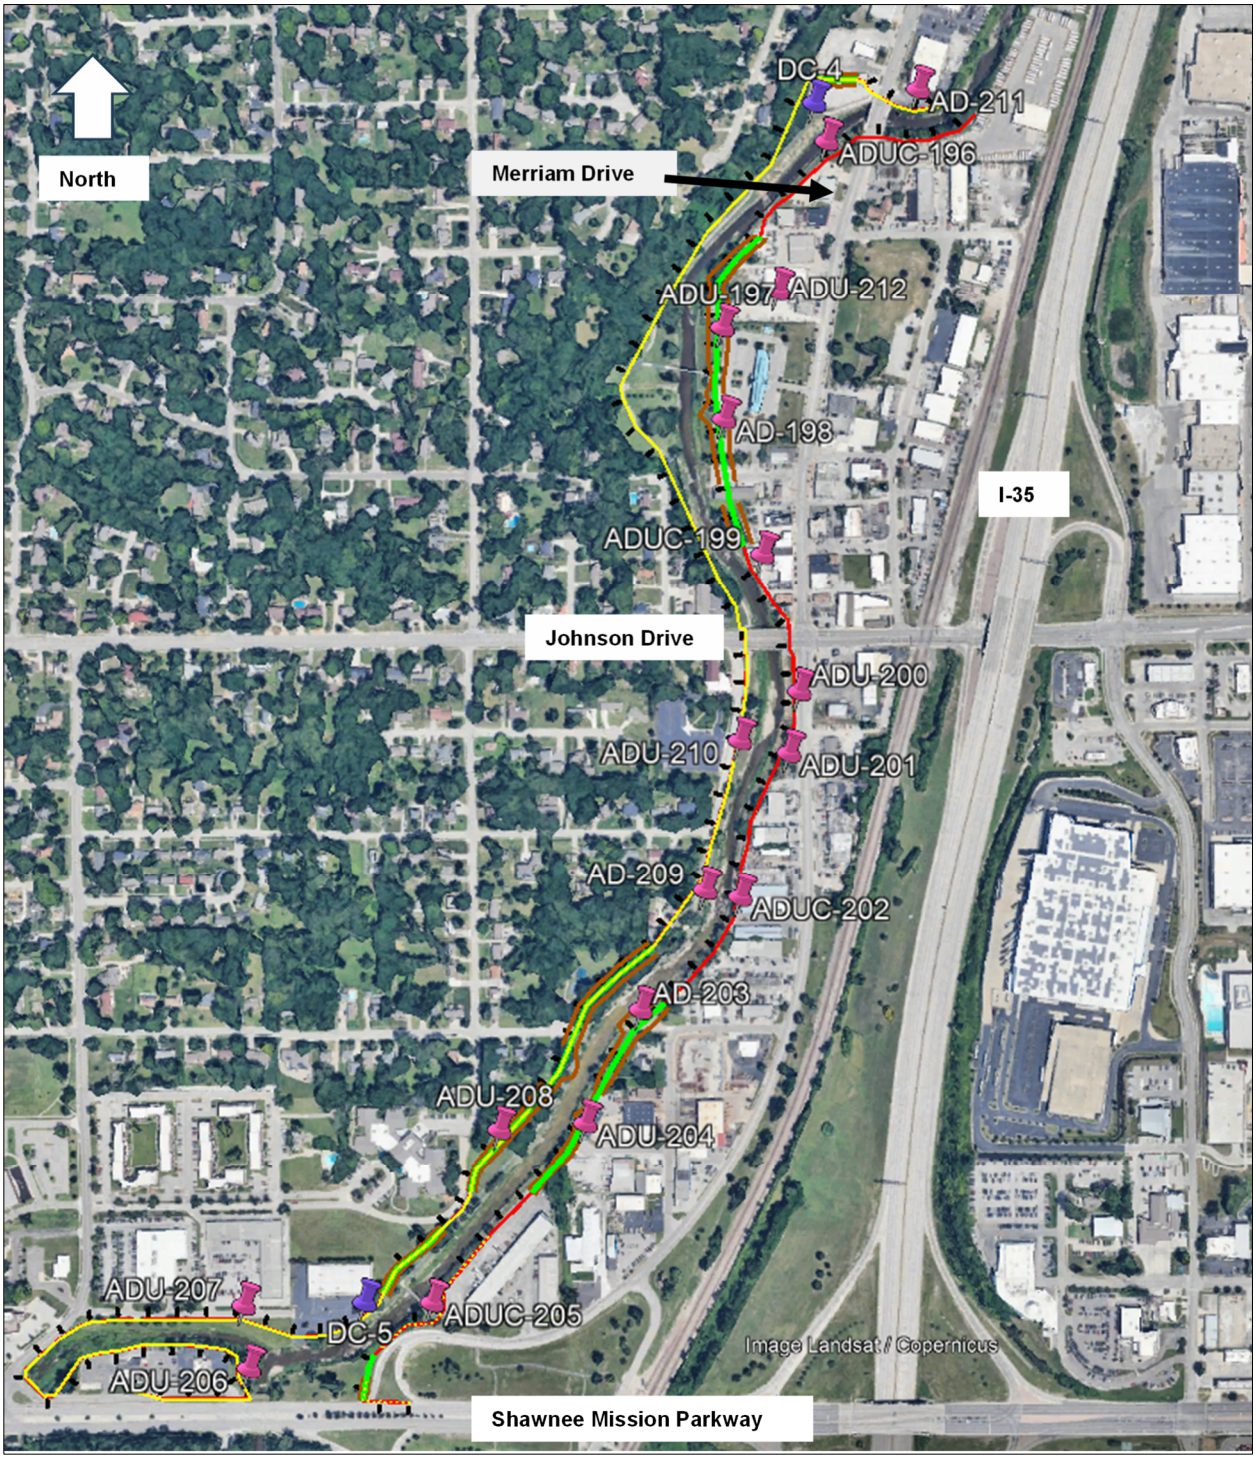
In 2023, USACE conducted a subsurface investigation to collect subsurface samples for the design and construction of the floodwall and levee system on Upper Turkey Creek. A total of 17 borings were conducted as part of this investigation. Boring logs are included in Appendix A. Split spoon samples were taken every 5 feet until refusal. Relatively undisturbed Shelby tube samples were taken at predetermined depths.

The target depth for all borings was in a range between 12.9- and 23-feet deep, which was based on historical borings in the area. While most soil samples met their target depth, some borings reached refusal between 6 and 8 feet in depth due to the shallow bedrock, resulting in crushed Shelby tubes.

Groundwater was encountered in 7 of the 17 borings and ranged from 10.3 to 21 feet below grade. In five of the seven borings where groundwater was encountered, it was found within 2.5 feet of bedrock. During this investigation, performed between January and March, the water level in Turkey Creek was seasonally low. Groundwater is expected to vary seasonally with precipitation and creek levels.

Figure 6.1 shows an overview map of boring locations on aerial photograph. Feasibility Study Borings DC-4 and DC-5 are shown in purple, while the 2023 borings are shown in pink. The levee alignment shown is approximate and for general reference only; the project plans should be referenced for the current proposed levee alignment. Boring locations are also shown on existing conditions plans and proposed features plans in the plan set.

Figure 6.1. Boring Locations.



6.3.1 Environmental Contamination

Environmental contamination (petroleum) was found within borings ADU-212 and ADU-201. Boring ADU-212 contamination was old and deteriorated contamination from a leaking underground storage tank (LUST) site that was closed by the Kansas Department of Health and Environment (KDHE). Random fill was also found in the borings and included large pieces of railroad ties. It is assumed that the former tank pit was backfilled with readily available materials at the time.

Boring ADU-201 soil contamination was not a known KDHE site. The source of the contamination is unknown. The current building was not constructed until the mid-1980s, but historical aerials show a possible former gas station in the 1940s-50s. The contaminated soil was contained, and a soil sample was submitted to Terracon for lab analysis of hydrocarbons and volatile organic compounds. Lab analysis revealed the soil was above default target levels and above residential levels for medium-range hydrocarbons but below non-residential standards. There are no residences nearby on this side of Turkey Creek, therefore non-residential standards would apply. The drummed soil was placed on site and was picked up by Safety Kleen®.

6.3.2 Drilling and Sampling Methods

Recent borings were completed with a Diedrich D-90 truck-mounted auger/rotary rig with hollow stem augers. In the historical and recent USACE investigations, both disturbed and undisturbed samples of the overburden soils were obtained at 3-to-5-foot intervals. Samplers used were 1 3/8-inch standard split spoon and 3-inch or 5-inch, thin-wall Shelby tubes. The bedrock was cored with an NX size core barrel. In-between core samples, the borings were advanced through the bedrock using rock bit drilling.

6.3.3 Disturbed Soil Samples Collection

Standard Penetration Testing (SPT) using a split-spoon sampler was performed in general accordance with ASTM D 1586 to obtain disturbed samples at predetermined depths. The split-spoon sampler was driven a maximum depth of 1.5 feet for each sample. A 140-pound safety hammer was dropped approximately 30 inches to advance the sampler. The number of blows for each six-inch increment was recorded on the boring logs. The blow count value, or SPT N-value, corresponds to the sum of blows for the last two six-inch increments. Each SPT was driven the full penetration depth or until refusal, whichever occurred first, with refusal defined as a blow count of 50 for less than 6 inches of sampler penetration. Material collected from the split-spoon sampler was transferred into labeled glass jars and tightly capped for storage and later transport to the soils laboratory for testing.

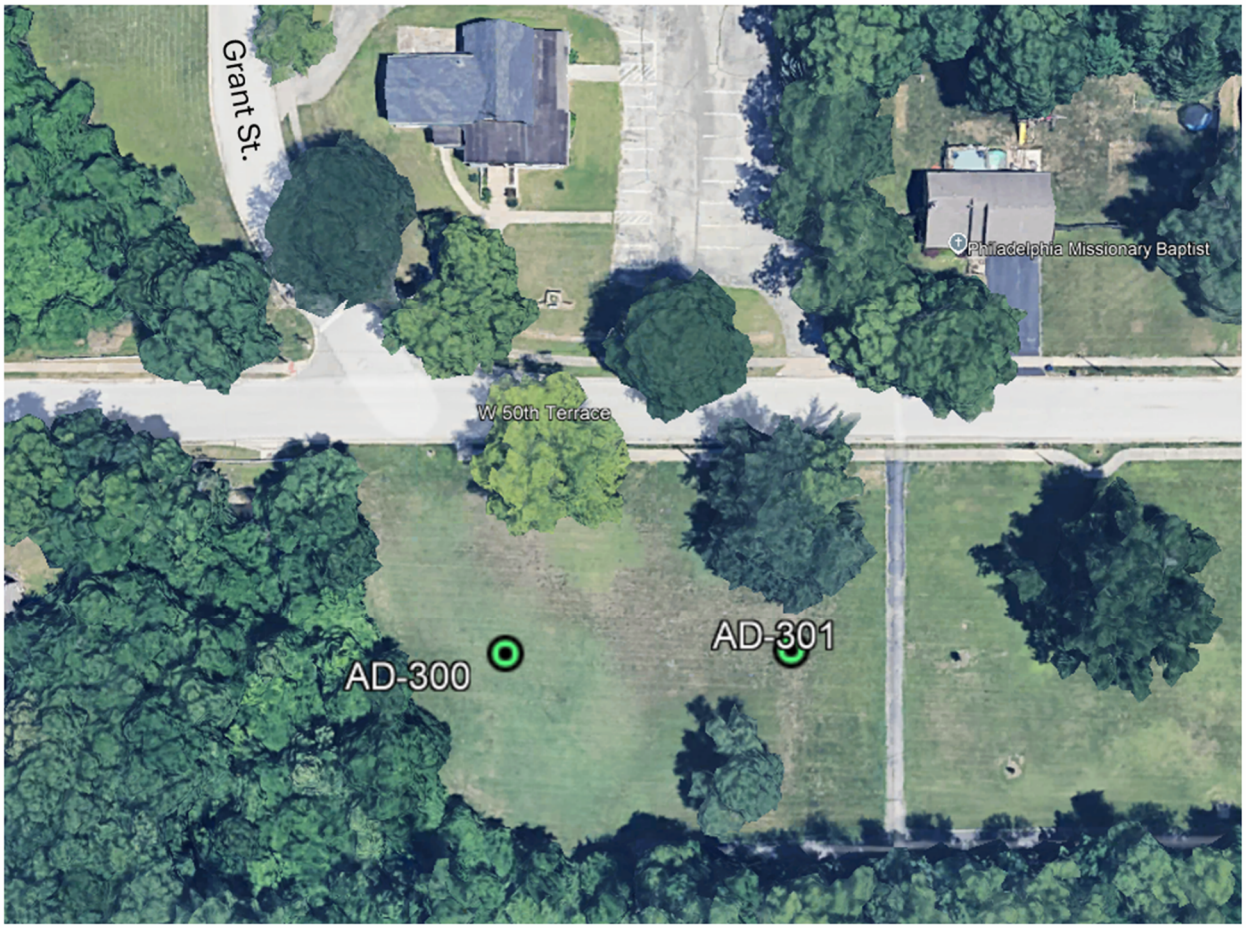
6.3.4 Undisturbed Soil Samples Collection

Relatively undisturbed samples were collected by pushing 3-inch or 5-inch outside diameter Shelby tubes in general accordance with ASTM D 1587. 3-inch Shelby tube samples were left in the tubes, with the open ends capped and taped, then sent to the lab for extruding and testing. 5-inch Shelby tube samples were extruded in the field and waxed for increased preservation.

6.4 2025 USACE Subsurface Investigation

Two additional soil borings (Borings AD-300 and AD-301) were drilled by USACE at a second proposed offsite borrow area, an open lawn area on the south side of W 50th Terrace and near Grant Street in Merriam, Kansas. This site appears to be relatively level and USACE is not aware of any current planned development at the site.

Figure 6.2. Boring Locations within 2nd Potential Borrow Area .



Borings extended to 15 feet below grade and encountered lean to fat clays and gravelly fill. Split spoon samples and bulk samples were taken for laboratory testing.

Laboratory testing was recently completed and is being incorporated into the final boring logs.

6.5 Future Subsurface Investigation

If the project is funded to continue, borings in proposed I-wall areas will be used to verify depth of bedrock to confirm if sheet piles can be driven to design depths without encountering bedrock, if predrilling through a small amount of rock will be required for sheet pile installation, or if T-walls need to be used in place of I-walls due to shallow bedrock. The I-wall area borings will be drilled to bedrock, expected at 10 to 25 feet below grade. It is proposed that approximately 10 borings be drilled in I-wall areas.

6.6 Historical Laboratory Testing

6.6.1 General

There is no record for historical laboratory testing on soil samples from the current project area. Laboratory tests were performed on soil samples from other reaches of Turkey Creek in the historical subsurface investigations by the USACE Missouri River Division Laboratory in Omaha, Nebraska. The tests generally included index tests and shear strength tests. The general results are summarized here for context.

6.6.2 Soil Classification Tests

Water content and Atterberg Limits tests were provided to classify soils and evaluate site stratigraphy. Based on the available data, the surficial soils are generally lean clays with liquid limits ranging from 32 to 49 percent and plasticity indices ranging from 13 to 29. The natural moisture content varied from about 21 to 30 percent.

6.7 Recent Laboratory Testing

6.7.1 General

Laboratory testing of soil samples collected from the borings along the levee alignment performed in 2023 was completed by Terracon and included Atterberg limits, sieve analysis, Unified Soil Classification System (USCS) classification, and moisture content. Additionally, Shelby tube density, consolidated-undrained (CU) and unconsolidated-undrained (UU) triaxial shear strength tests, and consolidation tests were performed on undisturbed soil samples extracted from Shelby tubes. Three rock cores were tested for compressive strength.

Laboratory testing of soil samples collected from the borings performed at the potential borrow site on the south side of W 50th Terrace near Grant Street in Merriam, Kansas was performed by the USACE St. Louis District. These tests included Atterberg limits, sieve analysis, USCS classification, and moisture content. In addition, bulk samples were tested for maximum dry density and optimum moisture content (standard Proctor). Remolded samples were created by compacting bulk samples to 95% of the maximum dry density, the compaction specified for levee embankment construction. CU triaxial shear strength testing was performed on remolded samples.

Appendix A contains the individual test data sheets and a summary table of these tests. Test results are also included on individual boring logs. Atterberg limit, sieve analysis, and USCS classification results were used to verify field soil classifications. Shelby tube density results were used to verify soil unit weights. Triaxial soil shear strength tests were used to establish soil strength parameters for global slope stability and for floodwall foundation design. Consolidation tests were used to estimate settlement of the in-situ soils due to levee construction.

Not all tests could be conducted as planned. Some of the Shelby tube samples had low recovery, were disturbed, or had substantial amounts of rock, making triaxial tests impossible. A second round of testing was attempted with additional Shelby tube samples to have more triaxial test results; however, these samples were also not usable.

6.7.2 Soil Classification Tests

Water content and Atterberg limits tests were provided to classify soils and evaluate site stratigraphy. Based on the available data, the surficial soils are generally lean clays with liquid limits ranging from 38 to 58 percent (only one sample over 50 percent) and plasticity indices ranging from 16 to 36 (only one sample over 28). The natural moisture content varied from about 21 to 30 percent.

Surficial soils at the borrow area on W 50th Terrace are generally lean clays with liquid limits ranging from 45 to 55 and plasticity indices ranging from 23 to 34. The natural moisture content varied from about 17 to 26 percent.

6.7.3 Unit Weight

Table 6.1 provides the unit weight of eight Shelby tube samples. The unit weight for the AD-198 sample appears significantly higher than expected, perhaps due to gravel in the sample.

Table 6.1. Soil Unit Weight.

Sample	Dry Unit Weight (per cubic foot [pcf])	Water Content (percent)	Moist Unit Weight (pcf)
ADU-197, 5 feet–7 feet	113.1	14.6	129.6
ADU-197, 10 feet–12 feet	95.8	26.0	120.7
AD-198, 10 feet–12 feet	124.2	28.9	160.1
ADUC-202, 5 feet–7 feet	96.6	23.2	119.0
ADU-204, 2 feet–4 feet	99.7	22.2	121.8
ADU-206, 5 feet–7 feet	103.1	18.1	121.8
ADU-207, 5 feet–7 feet	92.5	25.0	115.6
ADU-208, 1 foot–3 feet	94.3	25.4	118.3
Average (excluding ADU-197)	99.3	22.1	121.2

6.7.4 Consolidated-Undrained Triaxial Shear Strength

Table 6.2 provides CU shear strength test results on four samples along the levee alignment and Table 6.3 provides CU test results for two bulk samples from the borrow site on W 50th Terrace, remolded to 95 percent of the standard Proctor maximum dry density.

Table 6.2. Consolidated Undrained Test Results.

Sample	USCS	Liquid Limit	Effective Cohesion (psf)	Effective ϕ (degrees)	Total Cohesion (psf)	Total ϕ (degrees)
AD-198, 10 feet–12 feet	CL	38	0	37.4	0	23.9
ADUC-202, 5 feet–7 feet	CL	42	409.0	27.9	227.5	20.2
ADU-206, 5 feet–7 feet	CL	40	0	22.4	0	17.8
ADU-208, 1 foot–3 feet	CL	45	123.8	32.0	0	20.2
Average			133.2	29.9	56.9	20.5
Standard Deviation			192.9	6.3	113.8	2.5
Average minus one standard deviation			0*	23.6	0*	18.0

*negative value (see 6.9.2 and 6.9.4 for additional discussion)

Table 6.3. Consolidated Undrained Test Results – Borrow Site (Remolded).

Sample	USCS	Liquid Limit	Effective Cohesion (psf)	Effective ϕ (degrees)
AD-300, bulk	CL w sand	46	288.0	30.0
AD-301, bulk	CL	45	288.0	30.0

6.7.5 Unconsolidated-Undrained Triaxial Shear Strength

Table 6.4 provides UU triaxial shear strength test results on three samples. There was not enough usable sample for ADU-204 to run more than two tests.

Table 6.4. Unconsolidated-Undrained Test Results.

Sample	Confining Pressure (psi)	Cohesion (psf)	ϕ (degrees)
ADU-197, 10 feet–12 feet	7	1,237.0	0
	14	1,504.8	0
	28	2,494.1	0
	Average	1,745.3	0
ADU-204, 2 feet–4 feet	2.8	1,995.8	0
	10.4	2,766.2	0
	Average	2,381.0	0
ADU-207, 5 feet–7 feet	4.2	1,042.6	0
	9.7	1,478.9	0
	20.8	1,778.4	0
	Average	1,433.3	0
Average of Averages		1,853	0
Standard Deviation		483	0
Average minus one standard deviation		1,370	0

6.7.6 Consolidation Testing

Table 6.5 provides consolidation test results on five samples. The deeper sample had a smaller Overconsolidation Ratio (OCR) and larger compression index C_c, recompression index C_r, and initial void ratio e_o. The other four samples and the overall average were in a relatively close range. As C_c and C_r are in the numerator for calculation of consolidation settlement, it is conservative to add the standard deviation to the average. As e_o is in the denominator, it is conservative to subtract the standard deviation from the average.

Table 6.5. Consolidation Test Results.

Sample	USCS	Preconsolidation Pressure (tons-force per square foot [tsf])	Overburden (tsf)	OCR	C_c	C_r	e_o
ADU-197, 5 feet–7 feet	Gravelly CL	3.5	0.39	8.9	0.11	0.01	0.503
AD-198, 10 feet–12 feet	CL	3.2	0.88	3.6	0.23	0.03	0.876
ADU-204, 2 feet–4 feet	GC w sand	2.9	0.18	16.1	0.15	0.02	0.639
ADU-206, 5 feet–7 feet	CL w sand	4.1	0.37	11.1	0.16	0.03	0.667
ADU-208, 1 foot–3 feet	CL	2.3	0.12	19.2	0.11	0.01	0.791
Average					0.15	0.02	0.695
Average plus Std Deviation for C_c and C_r, Average minus Std. Deviation for e_o					0.20	0.03	0.57

6.7.7 Rock Core Compressive Strength

Table 6.6 provides rock core compressive strength test results for four samples.

Table 6.6. Rock Core Compressive Strength.

Sample	Elevation (feet)	Specimen Type	Compressive Strength (pounds per square inch [psi])
ADUC-196, 28.3 feet–28.7 feet	882.2–881.8	Shale	60
ADUC-202, 12.2 feet–12.6 feet	900.8–900.4	Limestone	12,560
ADUC-205, 15.1 feet–15.5 feet	913.7–913.3	Limestone	8,540
ADUC-205, 18.4 feet–18.8 feet	910.4–910.0	Shale	40

6.8 Subsurface Conditions

The levee site is generally comprised of undocumented fills underlain by alluvial lean clays. The alluvial soils also include silty lean clays, gravelly lean clays, and occasional clays with sand. Fat clay was only encountered in one sample. The lower portion of the alluvial lean clays, immediately above the bedrock surface, contains clayey gravel deposits. The clayey gravel is water bearing.

Fill soils contained occasional gravel and trace amounts of asphalt, brick, or concrete fragments but appeared to mainly be composed of lean clay. Petroleum odor was encountered at two locations, as noted in Section 6.3. Although the transition is difficult to pinpoint due to similar appearances where there is no obvious extraneous material, fill soils appear to extend approximately 5 to 10 feet below grade. Fill soils had medium stiff consistency on average in the soil borings performed for this investigation.

Natural alluvial soils also had medium stiff consistency on average.

Unlike most levee system locations in the Kansas City District, a continuous pervious zone of foundation sand in between the impervious blanket and bedrock was not encountered in the soil borings.

Subsurface rock was classified as weathered to competent shale and occasional limestone, which ranged from soft to moderately hard. Weathered shale was encountered at depths ranging from as shallow as 10.3 feet to as deep as 25 feet. Competent shale was encountered as shallow as 21.2 feet and as deep as 37 feet. Competent limestone was encountered as shallow as 8.7 feet and as deep as 13 feet. Soft limestone was only encountered in one boring location, at a depth of 18.5 feet.

6.9 Engineering Soil Property Development for Design

Design soil parameters used for underseepage and slope stability analyses are based on boring logs, laboratory testing, and typical properties based on soil classification.

6.9.1 Underseepage Design Soil Parameters

Table 6.7 shows design soil parameters for underseepage analysis.

Table 6.7. Underseepage Design Soil Parameters.

Property	Report Design Basis
Saturated Unit Weight of Impervious Blanket γ_{sat}	115 pcf
Permeability Ratio, Sand foundation material to impervious blanket (K_f/K_b)	400
Hydraulic Conductivity (k_{sat}) of Sand	0.003 feet/second

NWK typically uses saturated unit weight of 115 pcf for foundation materials. Shelby tube density tests show 115 pcf to be on the lower end of test results, but it is believed to be representative for the clayey fill and natural soils which do not contain gravel.

The permeability ratio of silty clay blanket material to a pervious substratum is given as 400 in the Kansas City District Underseepage Guidance.

Hydraulic conductivity values for sand are based on typical values for saturated soils (see Das, Geotechnical, p. 164). This value was used in feasibility analyses and design for the South Topeka Floodwall Modification Project. Assumed values were compared to permeability of pervious sand foundation for Missouri River Levee L-476, where 0.0026 feet/second (227 feet/day) was used (see DM No. 1 for 476-L, p. I-15).

6.9.2 Steady State Stability Design Soil Parameters

Effective (drained) soil strengths from CU testing were used for selecting steady state stability design soil parameters. Due to sampling difficulties, only four sets of tests were performed. The four resulting effective internal friction angles (22.4, 27.9, 32.0, and 37.4 degrees) were variable. Due to sample disturbance and gravel in samples, only two of the four test sets had reasonable stress-strain curves for all three samples tested at various normal stresses in each test set. These two test sets had effective results with internal friction angles and cohesion, 27.9 degrees and 409 psf for one and 32 degrees and 123 psf for the other.

As lab results were limited, the friction angle was also confirmed through correlations with Plasticity Index (PI) in UFC 3-220-10 (see Figures 8-13 through 8-15, Change 1, 11 March 2025). The fully softened friction angle derived from the correlations is taken to be equal to the normally consolidated peak value. Based on five consolidation test results on samples ranging from 1 to 12 feet below grade, the onsite soils are overconsolidated (overconsolidation ratios of 3.6 to 19.2). Normally consolidated strengths should be conservative for overconsolidated soils.

The average PI from 25 jar samples tested in 2023 (excluding four non-plastic samples) was 21.9. These correlations (in Figure 6.3, Figure 6.4, and Figure 6.5) show the average correlation for this PI results in a drained friction angle of 30 degrees and the average minus one standard deviation results in a drained friction angle of 28 degrees.

Figure 6.3. PI – Phi Correlation 1.

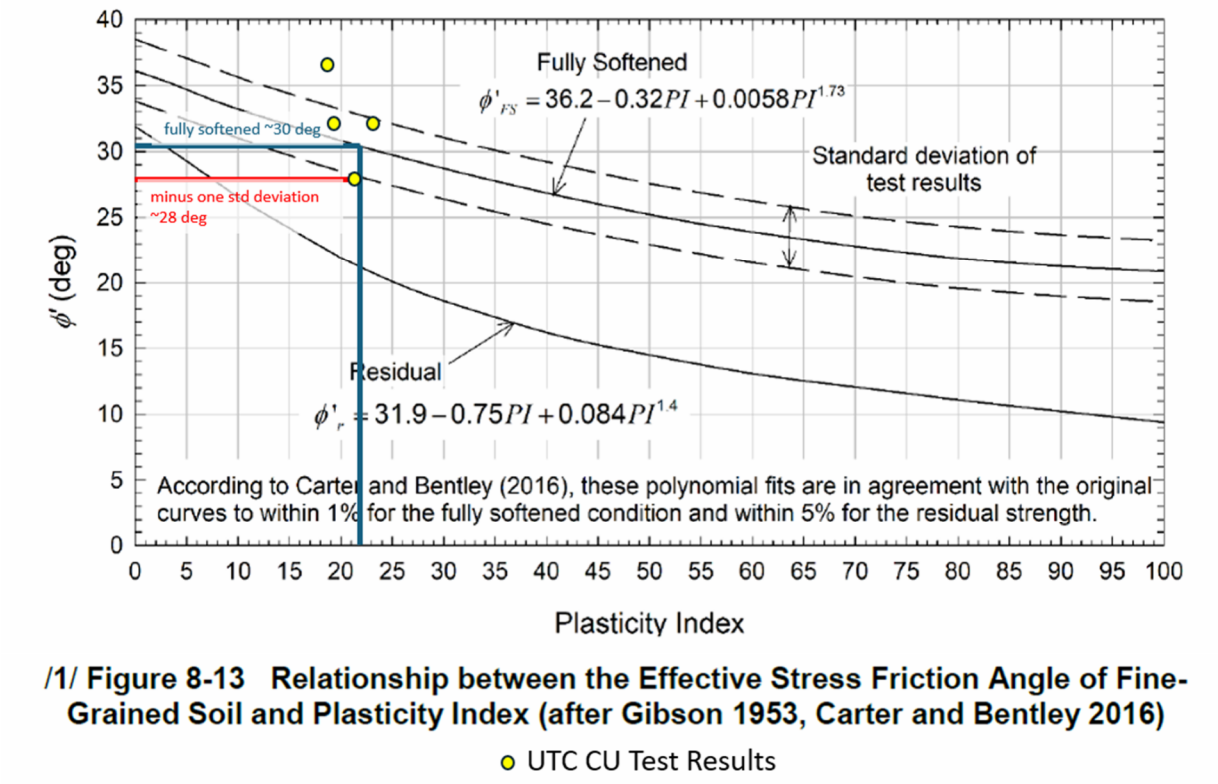


Figure 6.4. PI-Phi Correlation 2

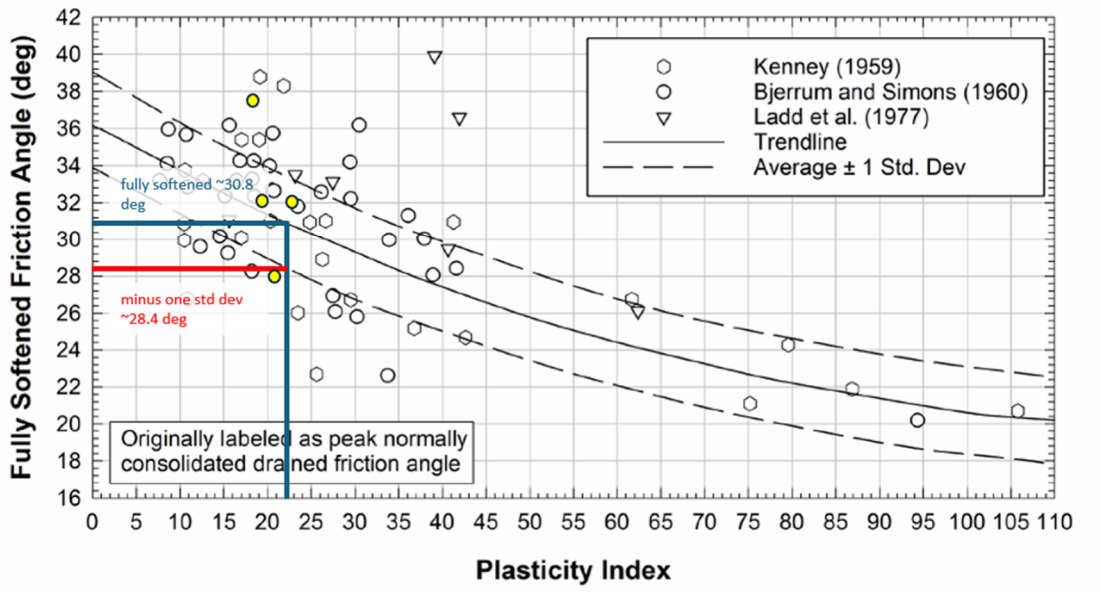

Figure 6.5. PI-Phi Correlation 3

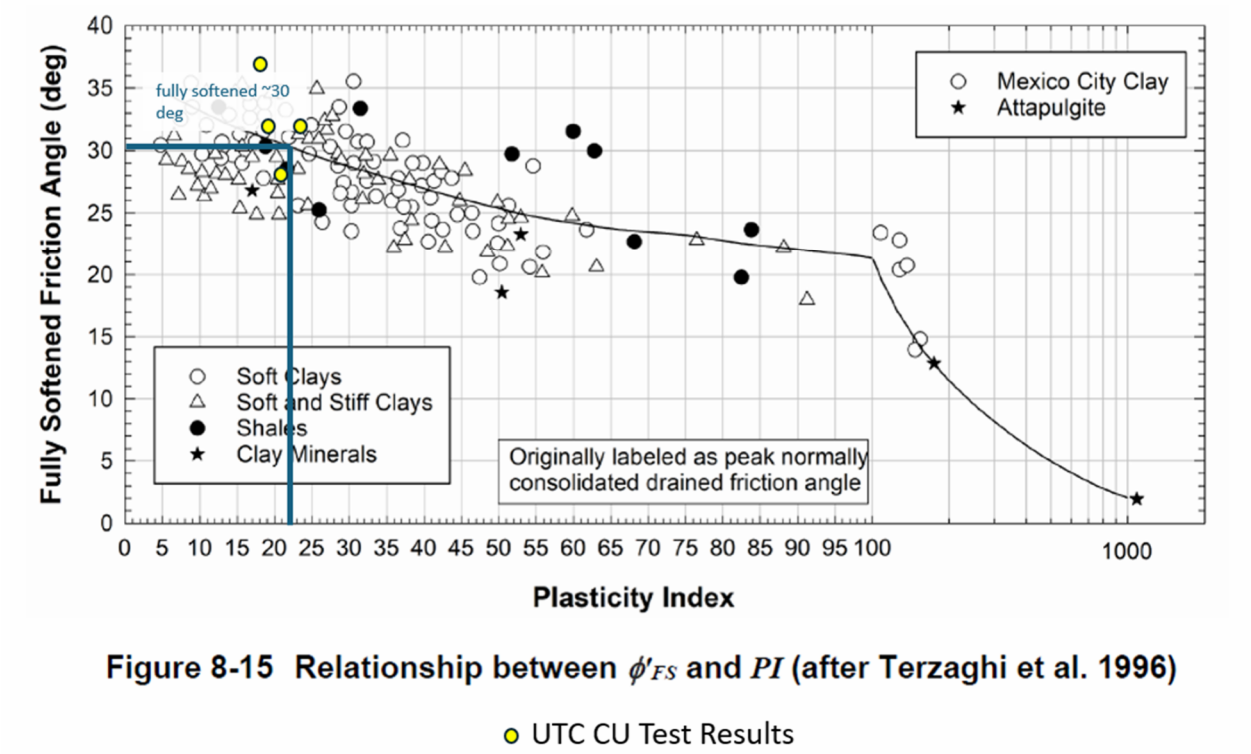

Figure 8-15 Relationship between ϕ'_{FS} and PI (after Terzaghi et al. 1996)

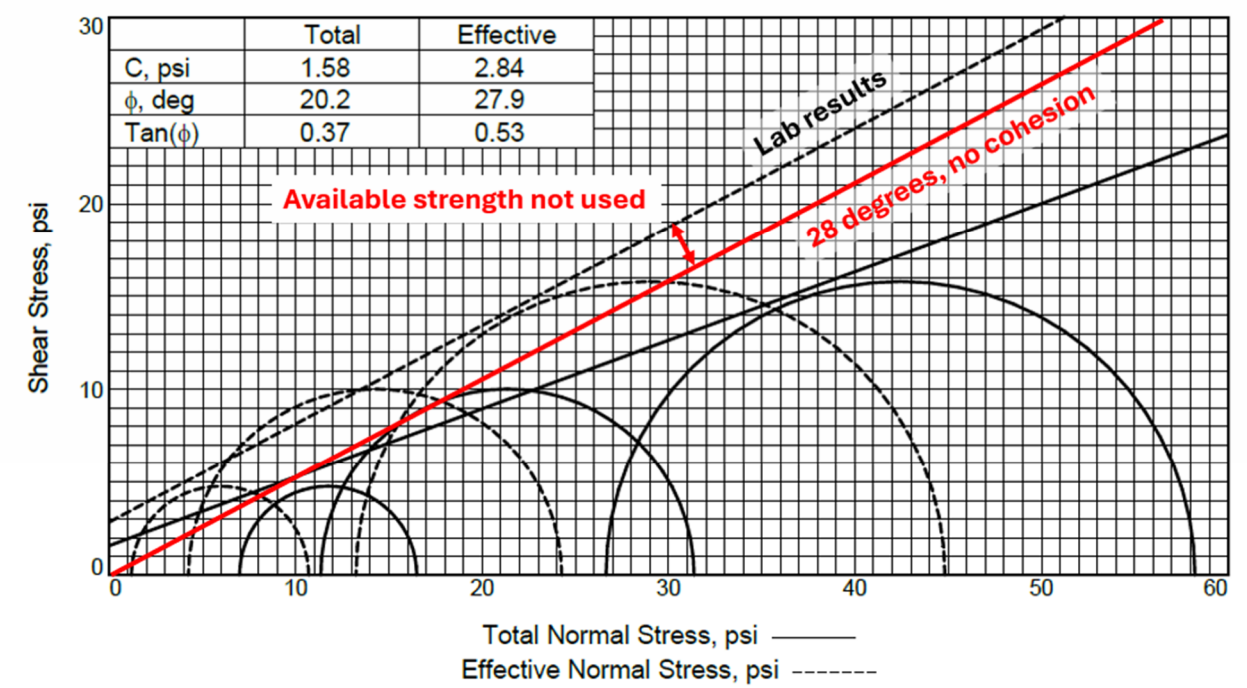
For drained strength parameters for structural stability calculations, I-wall rotational stability, drilled shaft calculations, and for the first stage of rapid drawdown, a drained friction angle of 28 degrees with no cohesion was conservatively used.

For steady state global slope stability calculations, using 28 degrees with no cohesion was resulting in unacceptable factors of safety for design. The Kansas City District typically does not use cohesion for drained strength parameters, but using an internal friction angle of 28 degrees with no cohesion does not allow the analysis to use all of the strength available from the test results. Using 28 degrees with no cohesion for steady state analyses was resulting in stability berms being required for a levee that is unlikely to see sustained loading. See

Figure ***6.6*** for the CU test result with the lower internal friction angle (from Boring ADU-202 from 5 to 7 feet below grade).

Figure 6.6. Lab Results vs No Cohesion Plot



The GeoStudio software used for slope stability analyses allows the use of a normal-shear strength function to define the drained shear strength. A curve was defined following the lab results at higher normal stresses and roughly following the curve of the first Mohr's circle back to a cohesion intercept of zero for lower stresses.

The normal-shear points were defined as shown and then adapted to a curvilinear function in GeoStudio (see Figure 6.7). This allowed for use of more of the strength from the laboratory test result while still using a cohesion intercept of zero.

Figure 6.7. Drained Strength Function

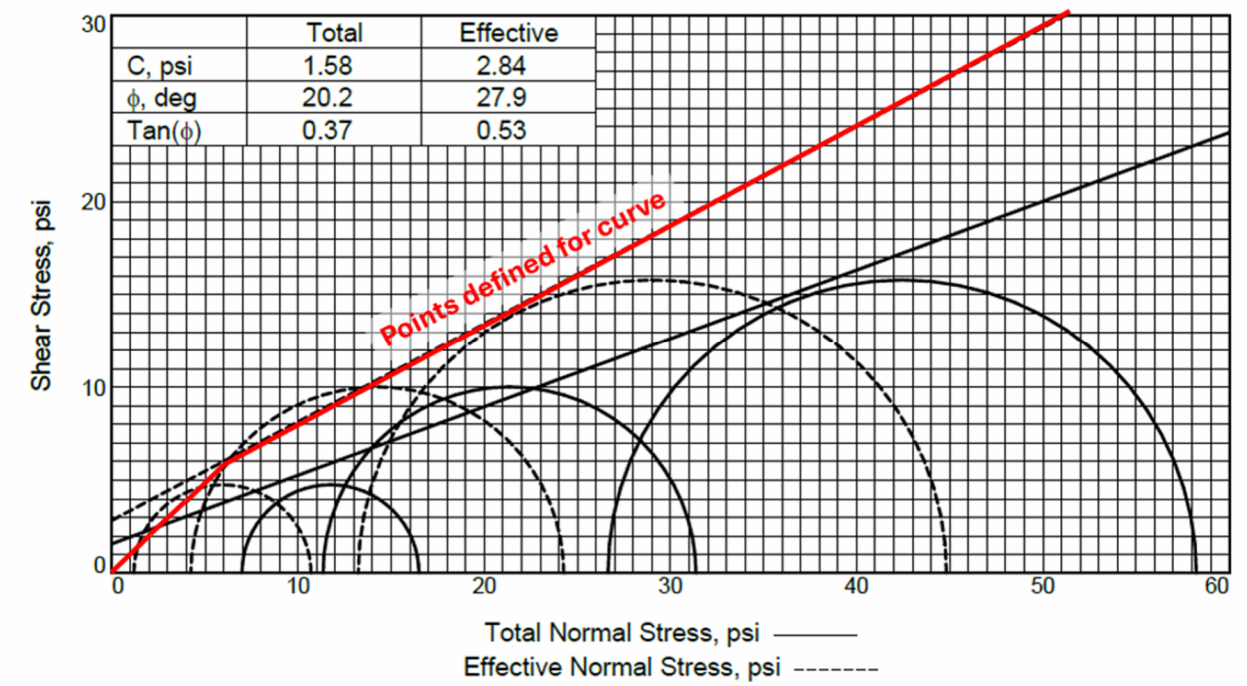


Figure 6.8. Curvilinear Strength Function.

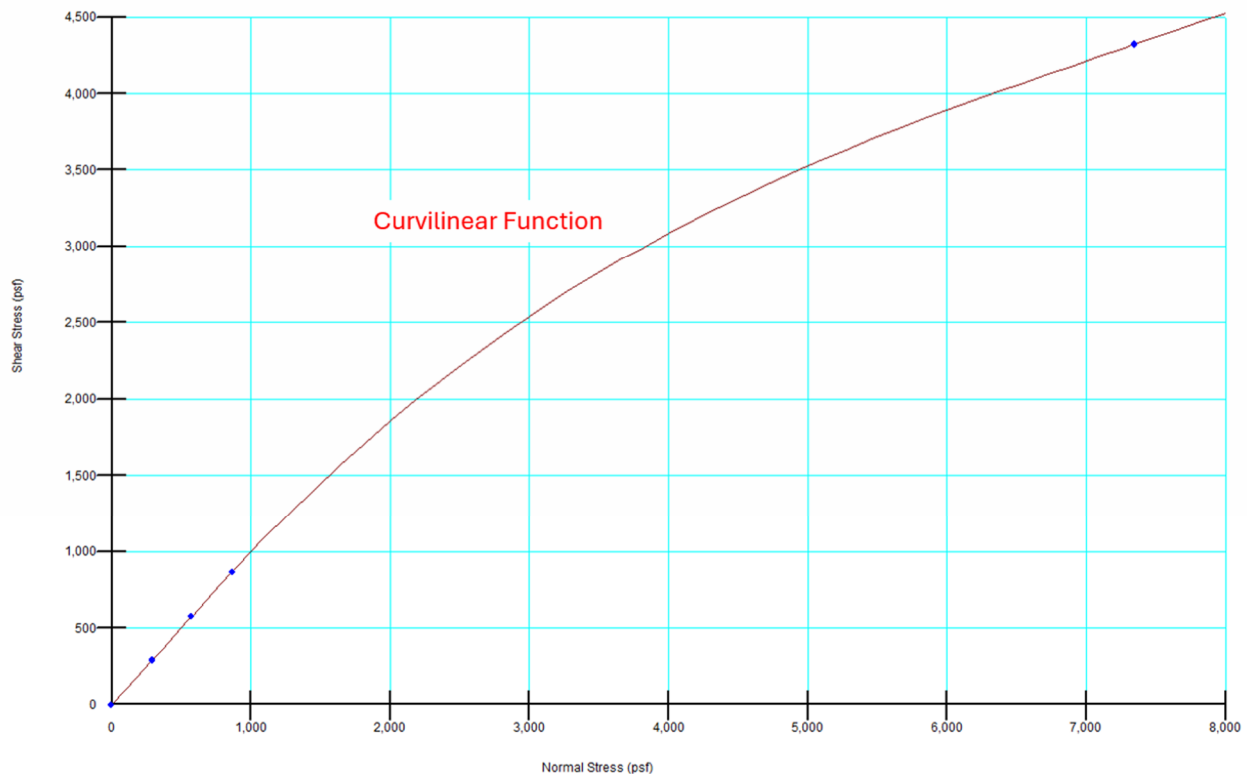

Soil properties for compacted fill in the embankment for steady state use the same curvilinear function as their strength is expected to be no worse than that of the in-situ materials.

Remolded CU triaxial shear strength tests were performed on bulk samples from the potential borrow site at W 50th Terrace. These samples were compacted to match the specified compaction for embankment materials (95 percent of the standard Proctor maximum dry density). Both bulk samples had an effective friction angle of 30 degrees. An effective friction angle of 28 degrees was selected for use for the embankment. It is unknown what borrow sources will be used, but the remolded CU tests show this friction angle is reasonable for the type of soil and the degree of compaction that would be used for the embankment.

Although a continuous pervious zone of foundation sand was not encountered in the soil borings, a pervious stratum has been included in underseepage and stability analyses, as described in Section 7.1.4. Properties are based on typical properties of foundation sands at other levee design projects such as the Argentine Levee Raise in Kansas City, Kansas.

The curvilinear function shown above was used for drained strengths of impervious fill and blanket for slope stability calculations in GeoStudio. For other applications, including drained bearing capacity, the strengths in Table 6.8 were used.

Table 6.8. Steady State/Drained Material Properties.

Material	Unit Weight (pcf)	Cohesion (pcf)	Phi (degrees)
Impervious Fill (Embankment)	120	0	28
Impervious Blanket	115	0	28
Pervious Stratum	115	0	31

6.9.3 End of Construction Stability/Undrained Bearing Capacity Design Soil Parameters

Soil strength properties for end of construction stability or undrained bearing capacity are based on the undrained soil strengths from UU testing (see Table 6.9). Due to sampling difficulties, only three sets of tests were performed. The average cohesion minus one standard deviation was 1,370 psf (see Table 6.4). Based on the limited number of tests, a cohesion of 1,000 psf was chosen for design for both the embankment and impervious blanket.

Table 6.9. End of Construction/Undrained Material Properties.

Material	Unit Weight (pcf)	Cohesion (pcf)	Phi (degrees)
Impervious Fill (Embankment)	120	1000	0
Impervious Blanket	115	1000	0
Pervious Stratum	115	0	31

6.9.4 Rapid Drawdown Stability Design Parameters

Table 6.11 shows soil strengths for rapid drawdown stability. The effective stress plots of the CU triaxial shear strength testing with pore pressure measurements were used for selection of drained shear strengths for in-situ soils for steady state analysis/first stage calculations (Basic

Strength on SLOPE/W). The total stress plots of the same test were used for selection of undrained shear strengths for second stage calculations (R Envelope on SLOPE/W). The average minus one standard deviation for R Envelope friction angle was 18 degrees (see Table 6.2). Only one of the four test results showed cohesion. As noted above, due to sample disturbance and gravel in samples, only two of the four test sets had reasonable stress-strain curves for all three samples tested at various normal stresses in each test set. One of these showed a cohesion of 227.5 psf.

The analysis method for rapid drawdown requires R Envelope cohesion to be more than the cohesion used for the first stage/steady state calculations. A cohesion value of a few hundred psf is typically used for the R Envelope for rapid drawdown at Kansas City District projects based on more extensive testing on similar materials, see Table 6.10. An R Envelope cohesion of 200 psf was selected for design.

Table 6.10. Rapid Drawdown Design Parameters – Nearby Projects.

Material	Unit Weight (pcf)	Basic Cohesion (pcf)	Basic Phi (degrees)	R Envelope Cohesion (pcf)	R Envelope Phi (degrees)
Argentine Impervious Fill (Embankment)	120	0	26	300	17
Argentine Impervious Blanket	115	0	26	300	17
Armourdale/CID MO CL Fill	120	0	32	150	22
Armourdale/CID MO Alluvial ML	110	0	29	850	18
Armourdale/CID MO Alluvial CL	115	0	31	300	20
Armourdale/CID MO Alluvial CH	120	0	23	600	11
Average				416	17.5

Table 6.11. Rapid Drawdown Material Properties.

Material	Unit Weight (pcf)	Basic Cohesion (pcf)	Basic Phi (degrees)	R Envelope Cohesion (pcf)	R Envelope Phi (degrees)
Impervious Fill (Embankment)	120	0	28	200	18
Impervious Blanket	115	0	28	200	18
Foundation Sand	115	0	31		

6.9.5 Settlement Parameters

The average values from consolidation testing with one standard deviation in the conservative direction were used for settlement calculations (see Table 6.12). See lab results in Table 6.5.

Table 6.12. Consolidation Parameters.

C_c	C_r	e_o
0.20	0.03	0.57

The design overconsolidation ratio (OCR) was varied by depth incorporating the consolidation testing results from this project and from similar alluvial clay soils at the Argentine, CID Missouri, and Armourdale levee raises nearby along the Kansas River (see Figure 6.9, test results in Table 6.13, and larger plot of the figure in Appendix B.5).

As the Upper Turkey Creek alluvial clay soils had similar behavior to the alluvial clay soils at the other projects at shallow depths, a power trendline was created for all of the test results to develop design OCR vs. Depth for shallow and deeper depths (see Table 6.13).

Figure 6.9. OCR vs Depth Trendline.

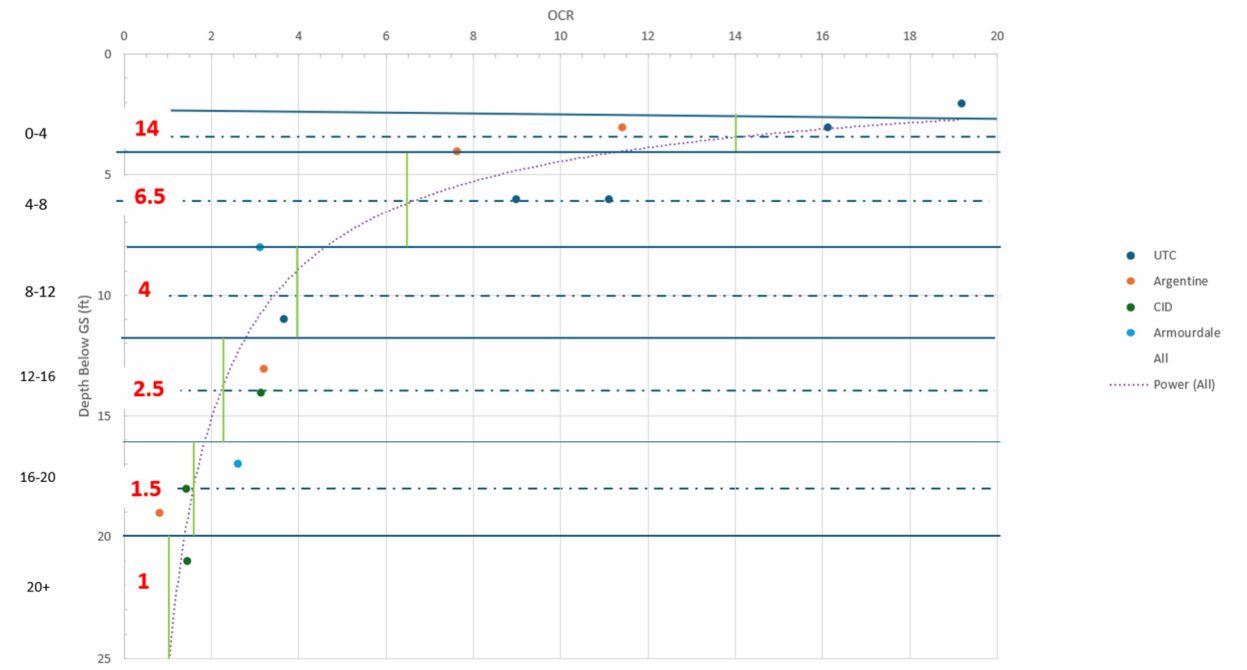

Table 6.13. Design OCR vs. Depth.

Depth below Grade (feet)	OCR
0-4	14
4-8	6.5
8-12	4
12-16	2.5
16-20	1.5
20+	1

6.9.6 Seismic Parameters

A soil seismic site class of D was used for initial assumptions for floodwall design. This corresponds to a shear wave velocity for medium dense sand or stiff clay in the top 100 feet. Depth of bedrock varied from 6.5 to 27.8 feet below grade, with an average depth of 14 feet and an average depth plus one standard deviation of 20 feet. The upper soils generally had medium stiff consistency. Based on shallow bedrock, using site class D with an average shear wave velocity corresponding to a stiff clay is satisfactory.

7.0. GEOTECHINCAL

Part 7 discusses levee embankment design and geotechnical aspects of floodwall design, including underseepage control, global slope stability, settlement, and slope protection. Local stability of floodwalls, such as sliding and overturning, and structural considerations for floodwalls are included in Part 9.

The levee system stationing used in this section refers to the August 2025 alignment provided by the Kansas City District Engineering Division, Geotechnical Branch, Civil Design Section (EDG-C). The levee alignment and stationing are constantly being adjusted during design. The river centerline stationing is also provided as an alternative means of designating locations in the levee system. This stationing is expected to remain consistent through the design project while levee stationing may continue to change.

In addition, the levee and floodwall cross sections analyzed for underseepage and slope stability are based on the August 2025 alignment. Portions of the left bank system have since been removed to improve interior drainage as part of Refinement 4. Other levee and floodwall top elevations and locations have had numerous small adjustments and will continue to be refined. The cross sections analyzed based on the August 2025 alignment are considered representative of the levee and floodwall heights, geometries, and soil conditions in the current design.

7.1. Underseepage

The following sections discuss underseepage criteria, design methodology, and recommended improvements.

7.1.1. Design Criteria

The underseepage requirements currently used in Pre-construction Engineering and Design (PED) work in the Kansas City District are contained in a memorandum dated 8 April 2015 with subject, “Missouri River Levee System (MRLS) R471-460 & L-455 Pre-Construction, Engineering, and Design (PED); NWK 2013 Underseepage Criteria; Revised per USACE-HQ Comments.” This memorandum was reviewed and approved by the Northwestern Division and USACE Headquarters for use in PED projects in the Kansas City District. The Northwestern Division also approved the memorandum for use as *Regional Criteria*, to be applied to design of underseepage berms for other projects in Northwestern Division districts until revisions to EM 1110-2-1913 are completed. Appendix B contains the full document.

Significant requirements in the memorandum include:

- Vertical Gradient Factor of Safety (FS) of 1.6 required at landside levee toe with water at the top of levee, as opposed to feasibility requirement of FS of 1.1 with water at top of levee and FS of 1.5 with water at design surface, three feet below top of levee
- Vertical Gradient FS of 1.0 required at berm toe as opposed to feasibility requirement of 1.1 beyond the berm toe
- Horizontal gradient ratio of 1.6 required at underseepage berm toe
- Generally recommended minimum berm width of 150 feet for new berms

Horizontal seepage gradient, or creep ratio, relates to the likelihood of sand boils at the levee or berm toe piping backwards to create a conduit beneath the levee. The critical horizontal gradient is considered to be 1/5 for fine sands and silts, typical of the Missouri River floodplain, as discussed in the referenced criteria. For earthen levees, the length of creep is defined as the distance from the effective seepage entrance to the first exit point for seepage; the landward toe

of the underseepage berm. This horizontal seepage gradient requirement is factored into the minimum required berm width. Table 7.1 summarizes the requirements.

Table 7.1. Underseepage Criteria.

Design Issue	Northwestern Division 2015 Criteria[1]
Levee Landside Toe Vertical Underseepage Gradient FS (for feature design)	$FS_{i\text{-}v}$>1.6, water at levee top
Underseepage Berm Toe Vertical Underseepage Gradient FS	$FS_{i\text{-}v}$>1.0, water at levee top
Underseepage Berm Toe Horizontal Underseepage Gradient[2] Ratio	$i_{h\text{-}c}/i_h$>1.6, water at levee top
Minimum Berm Thickness—Levee Toe	3 feet
Minimum Berm Thickness—Berm Crown[3]	1 foot
Berm Thickness Increase for Shrinkage and Consolidation	Adjust to account for settlement[4]
Berm Slope for Surface Drainage	Grade for positive drainage away from levee

[1]Requirements taken from Table 6 in referenced memorandum

[2]From referenced criteria: $i_h=H/(X1+L2+W)$

[3]Berm crown is the toe of the berm at the full required width. From this point (where the berm is 1-foot thick) the berm should slope down at a 1V:3H slope to existing grade.

[4]In practice, a 25 percent increase is used if no consolidation data is available.

The above criteria are generally applied to design of new levees or proposed levee modifications. Although the criteria were developed for Missouri River, the floodplain materials along Upper Turkey Creek are similar and the criteria may also be applied there.

7.1.2. Analysis Method

The general procedure outlined in EM 1110-2-1913, *Design and Construction of Levees – Appendix B.4,* (2000) was to calculate the FS for vertical underseepage gradient for the natural blanket and the excess head at the landside levee or floodwall toe. The design water surface for underseepage analysis is the top of levee or top of floodwall elevation. The excess head at the landside toe is assumed to be acting at the bottom of the blanket.

Variations from the manuals follow:

- Established hydraulic conductivity ratios for the Missouri River drainage basin (of which Upper Turkey Creek through the Kansas River is a tributary) relating to different blanket material types were used for underseepage calculations instead of horizontal and vertical hydraulic conductivity values for the pervious zone and impervious blanket zone material types, respectively. The hydraulic conductivity ratios were selected based on values from the Kansas City District Underseepage Guidance and the 2015 Regional Underseepage Criteria (see Appendix B). These values have long been established as appropriate for the floodplains within the Kansas City District. These values were developed from the 1962 Missouri River Division Conference in Omaha, Nebraska, based on experience with the Missouri River during the 1952 flood.

- The analysis assumes an infinite landside blanket unless a known exit point or seepage block is present.
- Rigorous blanket thickness transformation was generally not performed except to discount silty sand and coarser material below the blanket silts and clays. Sand lenses above the bottom of the blanket are included in the blanket thickness if they appear to be isolated from the lower pervious zones.
- If an underseepage berm is present or being designed, only half of the berm width is included in the L2 term when calculating FSi at the toe of the berm. This generally adds a small amount of conservatism to the calculations.

While underseepage berm requirements are provided here for reference, note that no underseepage berms are proposed for this project.

7.1.3. Design Assumptions

The design top of levee or floodwall is based on the profile provided by EDG-C.

The design water loading is to the top of levee or floodwall. While Upper Turkey Creek is not expected to remain at top of levee elevations for prolonged periods, this design was performed to bracket that worst case scenario.

Ground surface elevations are based on topographic survey by others provided by EDG-C. Elevations are based on the NAVD 88 vertical datum.

The subsurface profile is based on two historical soil borings (from 2002) and 17 recent soil borings (from 2023) performed within the project area.

The levee was divided into representative reaches for analysis based mainly on top of bedrock elevation (see Figure 7.1). Soil stratigraphy and site geometry, including distance from the levee system alignment to the creek, were relatively consistent throughout the system while depth to bedrock increased from upstream to downstream (south to north). In general, the cross section with the tallest levee or floodwall was analyzed within a particular reach. Bottom of blanket elevations and top of bedrock elevations for design cross sections are based on the nearest borings or interpolated between borings (see subsurface characterization in the Boring Profile in Appendix B.1).

Figure 7.1 Levee Design Reaches.

Table 7.2 provides the approximate reach boundaries with river centerline stationing.

Table 7.2 Levee Design Reaches.

Reach	UTC Centerline Stationing
1	0+00 to 17+60
2	17+60 to 29+50
3	29+50 to 38+60
4	38+60 to 57+80
5	57+80 to 66+00

The landside ground elevation was taken as the elevation at the landside levee toe or floodwall location. In general, the topography is relatively flat at the system alignment and then slopes up landward of the levee, especially on the left bank (west side of Turkey Creek). The riverside elevation is taken at the riverside levee toe or floodwall location and is generally the same as the landside ground elevation. The topography then slopes down to the creek bank.

The riverside seepage length (L1) was taken as the distance from the riverside levee toe or floodwall location to the creek bank. The soil borings did not show a consistent pervious layer between the impervious blanket and bedrock, so the seepage entrance was taken as the creek bank rather than a bottom of blanket elevation along the riverside slope.

The levee seepage length (L2) was taken as the levee width. A 10-foot crest width and 1V:3H side slopes were assumed. For floodwalls, L2 was taken as the footing width. I-wall areas within T-wall areas were not analyzed separately for underseepage.

A permeability ratio of 400 was used for ratio of hydraulic conductivity of the foundation sand to hydraulic conductivity of the impervious blanket. This corresponds to a typical value for a silty lean clay material in the Kansas City District underseepage guidance.

The soil stratigraphy along the proposed levee system alignment is different from most Kansas City District projects in that a continuous pervious layer or foundation sand was not encountered between the impervious blanket and bedrock. Bedrock is also relatively shallow. The blanket theory spreadsheet used for underseepage calculations in the Kansas City District and used to calibrate the seepage model for slope stability calculations in GeoStudio is based on the presence of a pervious zone to transmit seepage where underseepage pressures can build up at the bottom of the impervious blanket. Although the soil borings did not show a continuous obvious pervious zone, it is unconservative to assume that seepage will not be transmitted and underseepage pressures will not build up at the bottom of the impervious blanket. It is assumed that seepage will flow through voids and joints in the bedrock or through pervious zones of the upper weathered rock or gravelly clay.

As this means of seepage is difficult to quantify and bedrock in the blanket theory spreadsheet represents a relatively impervious layer, a pervious blanket was created between the impervious blanket and bedrock in the spreadsheet and the sensitivity of the results was checked based on varying the thickness of that pervious layer (varying the top of bedrock elevation). The top of bedrock elevation was adjusted in 10-foot increments until the change in FS for vertical underseepage gradient was less than 0.05. This adjusted worst-case, top of bedrock elevation was used in the underseepage analysis to account for any seepage pressures that could build up at the bottom of the impervious blanket. This adjusted top of bedrock elevation was also used in the slope stability models.

The top of bedrock elevation was adjusted for both the levee sections and floodwall sections.

7.1.4. Blanket Theory Analysis and Recommendations

Table 7.3 shows underseepage analysis results for various reaches.

Table 7.3. Underseepage Analysis.

Station	Protection	Vert. Gradient Factor of Safety (1.6 required)
Left Bank		
Reach 1		
13+20/UTC 0+50	Tallest Floodwall	**0.63**
26+80/UTC 14+50	Tallest Levee	2.61

41+40/UTC 49+50	Tallest Levee	1.73
Reach 5		
52+60/UTC 61+60	Tallest Floodwall	2.02

Although the adjusted top of bedrock elevation for worst case seepage results in low factors of safety for vertical underseepage gradient in some areas, the duration of loading above the levee toe is approximately two hours for a 1% AEP event or an overtopping event (see Figure 4.8). For infrequent short duration loadings, the levee foundation soils are unlikely to develop backward erosion piping. In addition, the soil profile generally consisted of nonerodable clay soils to bedrock; continuous foundation sand layers that are needed to form a pipe were not observed in the borings performed for this investigation. Underseepage berms and relief wells are not recommended.

An inspection trench will be excavated along levee centerline for all levee reaches. For levees 6 feet or higher, the trench will be 6 feet deep. For shorter levees, the depth of the trench will be

equal to the levee height. The trench width should be approximately 6 feet to allow for compaction equipment.

The inspection trench will allow for detection of any continuous pervious zones, voids, or unacceptable fill material. The trench will be backfilled with the excavated material compacted in lifts. If unacceptable material is encountered, it will be replaced with impervious fill to ensure there are no continuous seepage paths.

An inspection trench is not recommended for floodwall areas. Construction of the floodwall footing and key will require excavation to similar depths, allowing for inspection of the upper soils.

7.1.5. Floodwall Toe Drain

A toe drain will provide a filtered exit to prevent internal erosion of the floodwall subgrade soils from a concentrated leak at the footing-soil interface. The floodwall toe drain will consist of a 15-inch diameter perforated pipe wrapped in geotextile with coarse and fine aggregate. The drain will be routed to discharge through drainage structures or through standpipes at the ground surface. The toe drain will be used in T-wall areas but not in I-wall areas.

7.1.6. Internal Erosion in I-Wall Areas

Internal erosion in I-wall areas was evaluated by considering line of creep seepage along the sheet pile. This method evaluates whether the seepage path is long enough that internal erosion in that material would be unlikely to progress from the ground surface at the landside toe of the I-wall back to the ground surface at the riverside toe or to a vertical crack on the riverside of the tip of the sheet pile. A spreadsheet was used to determine Lane's weighted creep ratio for both the case with no crack and case with vertical crack on the waterside. Results are provided in Appendix B.

Best Practices in Dam and Levee Safety Risk Analysis states "To assess the likelihood of progression of backward erosion piping, the creep ratio for the reservoir level under consideration is compared to the minimum (or safe) creep ratio for the piping material. Progression of backward erosion would be expected if the creep ratio is less than the minimum creep ratio" (see page D-6-E-5, Version 4.1, USACE, July 2019).

The design sheet pile depths for rotational stability satisfied the critical creep ratio for a medium clay, which represents the known in-situ soil conditions.

7.2. Slope Stability

Section 7.2 discusses slope stability criteria, design methodology, and recommended improvements.

7.2.1. Design Criteria

Slope stability criteria are contained in EM 1110-2-1913, April 2000, and EM 1110-2-1902, October 2003. The design water surface is assumed to be the top of levee or floodwall for steady seepage analysis. The water surface is also assumed to be at the top of the levee or floodwall for end of construction analysis and for the first stage of rapid drawdown. Per the referenced engineer manuals, the factors of safety and shear strength parameters shown in Table 7.4 are required.

Table 7.4. Slope Stability Criteria.

Criteria	End of Construction	Long-Term Steady Seepage	Rapid Drawdown
Required FS for New/Improved Levees	1.3	1.4	1.0–1.2
Shear Strength Free draining soils	Use drained strength	Use drained strength	Use drained strength
Shear Strength Low permeability soils	Use undrained strength	Use drained strength	1st stage: drained 2nd stage: undrained 3rd stage: the lower of the two

The end of construction case represents undrained conditions for impervious embankment and foundation soils; excess pore water pressure is present because the soil has not had time to drain since being loaded.

Steady seepage case occurs when the water remains at or near full flood stage long enough so that the embankment becomes fully saturated, and a condition of steady seepage occurs.

Rapid drawdown represents the condition when a prolonged flood stage saturates at least the major part of the upstream embankment and then falls faster than the soil can drain. This causes excess pore pressure to develop, which may result in the riverside slope becoming unstable.

Earthquake loadings are not normally considered in levee stability analysis because of the low probability of earthquakes coinciding with periods of high water (see Section 6-5d, EM 1110-2-1913 [2000]).

Upper Turkey Creek is a flashy stream, which historically has rarely had water outside the channel for prolonged periods of time. Larger historical events such as the 1998 flood, however, demonstrate that more significant flooding is possible. For this design, it was assumed for the worst-case scenario that water could remain at the top of levee or floodwall long enough for steady seepage conditions to develop.

7.2.2. Method of Analysis

Slope stability of the levee embankment and floodwall reaches was evaluated for selected representative cross sections from those used in underseepage calculations. Those cross sections were then applied to similar reaches elsewhere in the levee system. Slope stability was analyzed using Seequent's GeoStudio SLOPE/W program using Spencer's method.

Cross sections were developed based on levee alignments and surveyed site topography provided by EDG-C. Landside and riverside levee slopes of 1V:3H were used for design.

A levee crest width of 10 feet was used for design. It is understood that the City of Merriam, Kansas, may desire to have larger crest widths in certain areas to allow for more room on the trail for bicyclists and pedestrians. Sensitivity analyses showed that larger crest widths do not have negative impacts on slope stability.

Seepage analysis was performed on GeoStudio's SEEP/W program to provide pore water pressure conditions for use in the stability analysis in SLOPE/W. In general, a water total head boundary condition equal to the top of the levee or floodwall elevation was applied to the

riverward slope and riverward edge of the model and a water total head equal to the landside ground surface elevation was applied to the landward edge of the model. In some cross sections where the landward ground surface slopes up significantly, even exceeding the top of levee elevation, the ground surface elevation at the landside levee toe was used for the water total head boundary condition at the landward edge of the model.

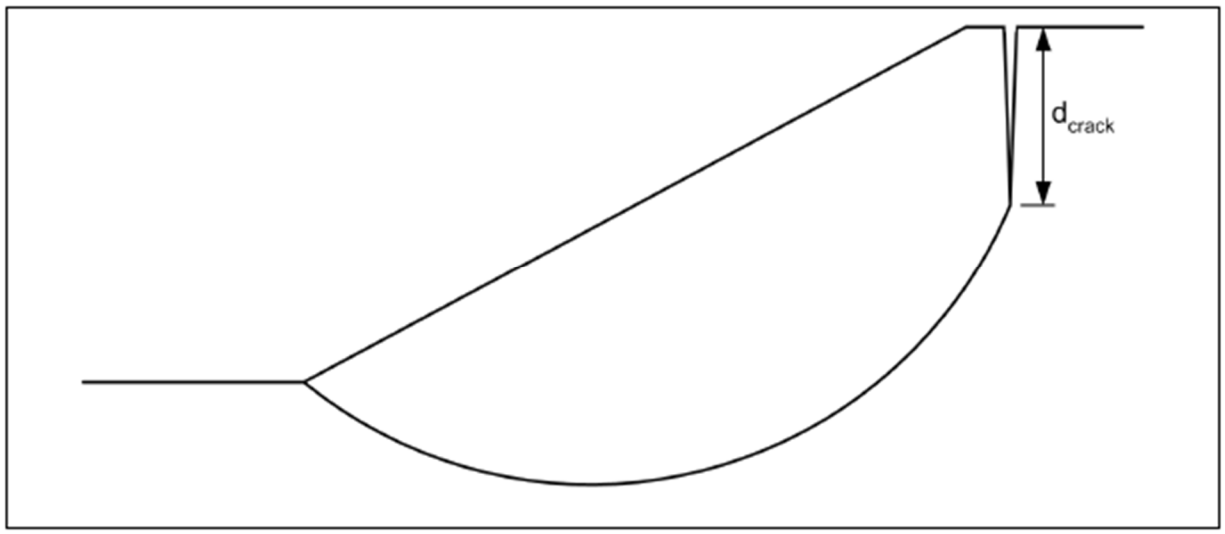
A potential seepage face boundary condition with water rate equal to 0 cfs was applied to the landside levee slope and landside ground surface and a no-flow boundary was placed at top of bedrock elevation with water rate equal to 0 cfs. The riverward extent of the model was taken as halfway into Upper Turkey Creek (approximately 25 feet). The landward extent of the model was taken as 2,000 feet landward of levee centerline, at which point there appeared to be no influence on the calculation results.

Hydraulic conductivity of 0.003 feet/second was used for foundation sand. A permeability ratio of 400 was used in the underseepage blanket theory spreadsheet calculations. This equates to a hydraulic conductivity of 7.5×10^{-6} feet/second for blanket materials and impervious embankment fill, using 0.003 feet/second for sand. The hydraulic conductivity of the embankment fill and impervious blanket was varied until the water total head at the bottom of blanket at the levee toe in the SEEP/W model matched the blanket theory calculations.

Critical slip surfaces were determined for a global stability breach with slip surface entry for landside slope failures on the riverside slope and slip surface including the entire crest. Slip surfaces not including the entire crest are considered maintenance breaches, which could be repaired before leading to levee breach. Federal levees are monitored frequently during high water events by both the local levee sponsor and USACE. Small slope breaches on the landside slope have occurred on Kansas City District levees after large rain events or during high water events in the past and emergency repairs or permanent repairs have been made before the slide progressed significantly. Multiple slides would need to occur in succession, enlarging the breach surface from an initial landside slope breach, while the river level remained high, before levee breach could occur.

Vertical tension cracks were added near the upper end of slip surfaces to eliminate tensile stresses from analyses (see Figure 7.1 from Figure C-22 in EM 1110-2-1902). When soils at the crest of a slope have cohesion, as in the end of construction case where undrained strengths are used, the analysis method results in negative values for the normal and shear forces, implying that the soils have tensile strength. Because few soils have tensile strength that can be relied on for slope stability, tensile stresses were eliminated from the analyses by adding water-filled tension cracks. Crack depths were estimated based on the undrained soil strength and then adjusted to not be greater than the height of the embankment and to not result in lower factors of safety. Tension cracks were added to the end of construction analyses. As a function was used for drained strength in the steady state analyses and cohesion was used in the second stage R Envelope strengths for rapid drawdown, steady state and rapid drawdown cases were spot-checked for negative normal and shear forces in the slip surface slices by viewing column information in GeoStudio. No negative normal or shear forces were found, so tension cracks were not added to those analyses.

Figure 7.2 Vertical Tension Crack.

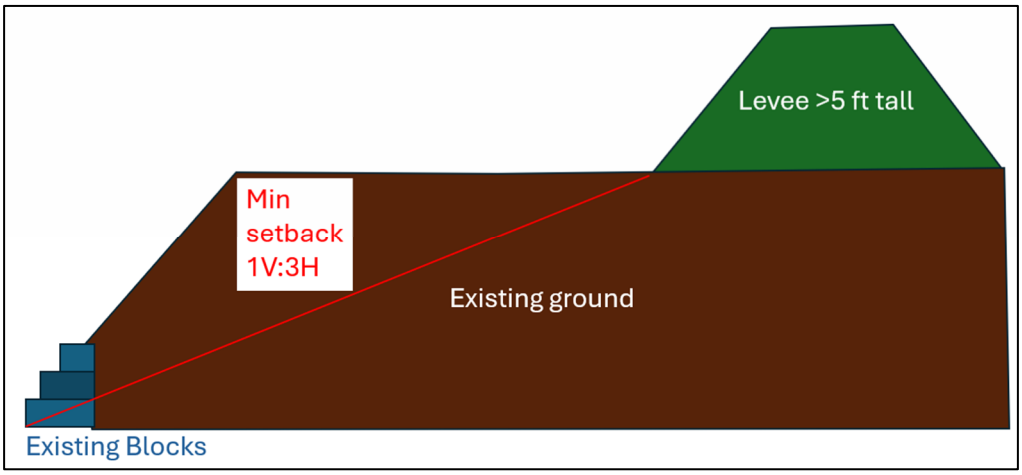


7.2.3. Analysis Results and Recommendations

Steady seepage, end of construction, and rapid drawdown stability were evaluated for representative levee and floodwall cross sections.

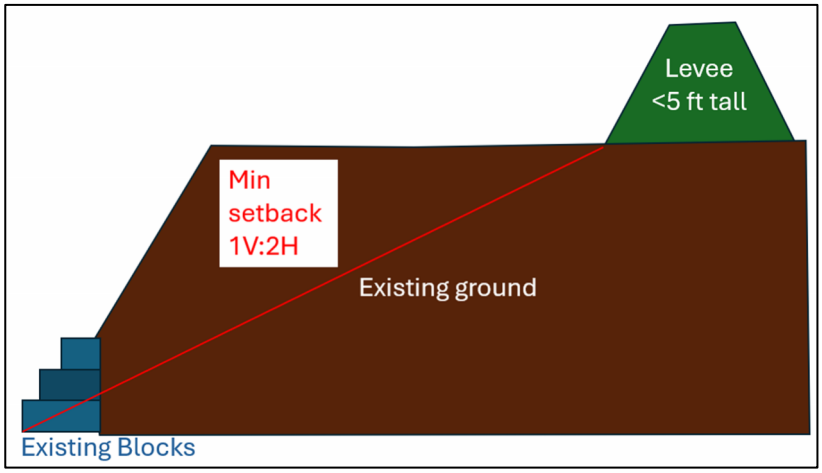
In general, the levee alignment was set so that a 1V:3H projected slope from the riverside levee toe would not intersect the face of the channel slope (limestone block wall or creek bank) above bottom of channel (**Error! Reference source not found.**).

Figure 7.3. General Levee Minimum Setback.



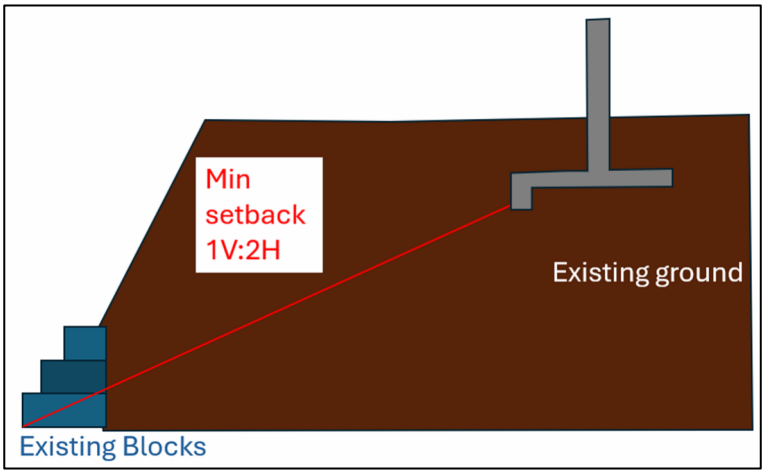
For levees less than or equal to 5 feet tall, the projected slope from the riverside levee toe to the face of the channel slope was allowed to be as steep as 1V:2H (Figure 7.4).

Figure 7.4. Minimum Setback for Levees Less than 5 feet Tall.



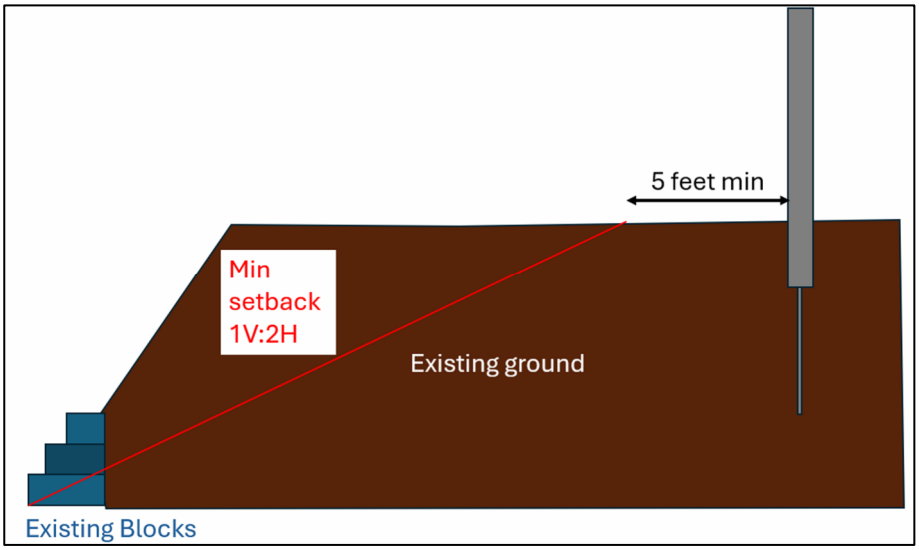
T-wall alignment was set so that a 1V:2H projected slope from the footing key would not intercept the face of the channel slope (Figure 7.5).

Figure 7.5. T-wall Minimum Setback.



I-wall alignments were set so that a 1V:2H projected slope starting at the ground surface 5 feet riverward of the I-wall would not intercept the face of the channel slope (Figure 7.6).

Figure 7.6. I-wall Minimum Setback.



The levee and floodwall setbacks provide acceptable factors of safety for steady state seepage, end of construction, and rapid drawdown. In addition, they provide a buffer in case of scour, failure of the limestone block channel wall, or failure of the channel slope. The analysis results show that multiple flood events with no repairs would be required for the levee or floodwall to have a global slope stability failure. The setback would need to be reduced to approximately 1V:1.5H or steeper slope from the face of the channel slope to the levee; then another flood would be required to produce a rapid drawdown situation. Even then, the failure would occur at a time of low water, reducing the risk of flood damage in the leveed area.

7.2.3.1. Steady State Seepage

Table 7.5 summarizes the reaches analyzed for steady state stability. All levee reaches analyzed met the minimum required factor of safety of 1.4 for a setback of 1V:3H. Some levee reaches also met the required factor of safety at reduced setbacks.

No realistic failure surface could be determined for the floodwall areas based on the soil properties, shallow bedrock, and no slope down on the landside. The failure surface intercepted shallow bedrock. A conservative landside slope was added to a cross section with deeper bedrock (RB R4 F 33+80/UTC 41+75), and a feasible failure surface was obtained with a high factor of safety (1.7). This confirms that the floodwall areas have acceptable factors of safety for global slope stability. The resisting forces on the landside with no slope down are too much for a credible failure surface to be generated. Block-specified failure surfaces were generated, as well as circular failure surfaces, and results were similar.

No realistic failure surface could be determined when steepening the slope from the floodwall footing to the creek bank to 1V:1.5H or 1V:1H.

A setback of 1V:2H was selected for design for floodwalls.

Table 7.5. Steady State Stability Results.

NS - no solution

7.2.3.2. End of Construction

Table 7.6 summarizes the reaches analyzed for end of construction (with water-filled tension cracks). All levee reaches met the minimum factor of safety of 1.3, including at the reduced setbacks.

No realistic failure surface could be determined for the floodwall area at R4 F 33+80/UTC 41+75 based on the soil properties, shallow bedrock, and no slope down on the landside, even with tension cracks. When introducing an artificial landward slope, stability results could be generated. For the other floodwall area, a failure surface was generated for the case with

tension crack. Block-specified failure surfaces were generated, as well as circular failure surfaces, and results were similar. Based on high factor of safety or error messages and lack of sensitivity to the slope in the other runs, floodwall stability runs with reduced slopes were not generated.

Table 7.6. End of Construction Stability Results.

7.2.3.3. Rapid Drawdown

Table 7.7 summarizes the reaches analyzed for rapid drawdown. The levee results show factors of safety near the 1.0 minimum when the setback is reduced to 1V:1.5H.

No realistic circular failure surface could be determined for floodwall areas based on the soil properties and shallow bedrock. Block-specified failure surfaces were generated, and factors of safety were satisfactory. Based on high factor of safety or error messages and lack of sensitivity to the slope in the other runs, floodwall stability runs with reduced slopes were not generated.

7.3. I-Wall Analysis

I-walls were considered as a cost-effective alternative to T-walls in areas where lower floodwall heights were sufficient and available right-of-way was limited between existing structures and the creek channel. The required penetration depth for rotational stability was the controlling factor and was used to determine where I-walls were feasible.

7.3.1. Rotational Stability

The USACE CASE program, CWALSHT, was used to analyze rotational stability for varying I-wall heights and establish the necessary sheet pile penetration depth. A maximum I-wall height of seven feet was determined per EM 1110-2-2502. Analyses were completed for wall heights from two to seven feet in half-foot increments. The analysis employed the same soil properties used in the T-wall and levee designs to maintain consistency. A bank slope of 1H:1.5V was used in all analyses to reflect the steepest bank slope existing along the alignment. Undrained and drained cases were considered. Early analysis indicated the drained case was the controlling case, as undrained conditions resulted in significantly shallower required penetration depths. An undrained example is included in Table 7.8 for comparison with the drained case for a 7-foot wall.

A sensitivity analysis was conducted to assess the influence of various input parameters. This included varying bedrock depths, evaluating scenarios with and without a pervious soil layer, and adjusting the distance between the wall and the streambank. Results indicated variations in bedrock depth influenced penetration depths the most. The model frequently encountered computational limitations when bedrock depth was reduced below a certain threshold. Removing the bedrock generally resulted in the most conservative penetration depths. Profile sensitivity was also examined by maintaining constant parameters while modifying the distance from the wall to the top of bank. This analysis concluded that the model was generally insensitive to these profile changes - doubling the distance from 10 to 20 feet reduced penetration depths by less than 0.5 foot on average.

Based on the comprehensive results of the CWALSHT analysis, a required sheet pile penetration depth was selected for each I-wall height, as summarized in Table 7.8.

Table 7.8. Required I-Wall Sheet Pile Penetration Depth for Varying Subsurface Conditions (ft).

I-Wall Height Above GS (ft)	No Pervious Layer		Pervious Layer at 15-20 ft BGS		No Bedrock (Continuous Clay Layer)		Selected Sheet Pile Penetration Depth
	Bedrock at 20 ft	Bedrock at 15 ft	Wall 10 ft from Bank	Wall 20 ft from Bank	Wall 10 ft from Bank	Wall 20 ft from Bank	
0.5	E	E	E	E	E	E	3
1.0	E	E	E	E	E	E	4
1.5	E	E	E	E	E	E	5
2	6.4	E	6.2	E	6.4	5.6	6
2.5	E	E	E	7.0	8.0	7.0	7
3	E	E	E	8.4	9.6	8.4	9
3.5	11.2	11.0	11.0	10.8	11.2	11.1	11
4	12.7	E	12.7	12.6	12.7	12.6	13
4.5	E	14.2	E	13.5	E	E	14
5	15.9	14.5	14.8	14.5	15.9	16.0	15
5.5	17.2	E	E	E	17.2	16.8	16
6	18.7	15.7	18.1	16.1	18.7	18.0	17
6.5	E	17.1	19.5	17.6	20.2	19.6	18
7	E (7.4)	18.0 (7.4)	E (E)	18.8 (E)	21.6 (7.4)	21.2 (5.1)	20

Note: "E" indicates the model encountered computational limitations and did not provide a solution. Undrained results for a 7-foot wall are in parentheses.

Wall heights below 2 feet produce errors in CWALSHT, used a linear projection (slope of 2) to select penetrations for 0.5, 1.0, and 1.5 ft wall heights.

7.3.2. Selection of I-Wall Ranges

Feasible I-wall ranges were determined based on the available penetration depths (existing ground surface to top of estimated bedrock). The flood protection alignment was provided by EDG-C and included the existing ground surface elevation, the proposed protection elevation, and type of protection (levee, floodwall, or none) for 20-foot segments. Bedrock depths were interpolated along the flood protection alignment based on available boring data, with separate interpolations performed for the left and right banks. Where borings were spaced more than approximately 1000 feet apart, the creek bed elevation was used to estimate bedrock depths. The height of protection above ground was determined from the provided survey data and rounded to the nearest 0.5 foot. The required penetration depth (per Table 7.8) was then assigned to each station based on the height of the protection (I-wall above-ground height). I-walls were recommended where the required penetration depth was equal to at least the

available penetration depth plus a one-foot buffer. Sections where available penetration was one to three feet less than the required penetration were identified as potentially I-wall suitable with the incorporation of grading, excavation, or a combination of the two. Floodwall sections with heights greater than seven feet were not considered. Recommended I-wall ranges are provided in Appendix B.

Critical sections within the floodwall ranges where I-walls were recommended were further analyzed to confirm required penetration depths were reasonable. Critical sections were selected based on wall heights and distances to the streambank—taller walls closer to the bank were prioritized. Separate CWALSHT analyses were completed for each critical section. The ground surface was modeled based on the lidar survey.

Additional sections were analyzed where I-walls were potentially suitable (as defined above). In these cases, the ground surface profile was modified to incorporate up to three feet of added fill at the base of the I-wall. Analysis of these reaches indicates that with the addition of fill, I-walls may be used. Further coordination with the Civil group would be needed to verify regrading is feasible in order to incorporate these I-wall reaches. Thus, I-walls are not shown in the current plans for these potentially suitable reaches.

Prior to I-wall construction, field verification of bedrock depths should be conducted.

7.4. Bearing Capacity for Floodwalls

Bearing capacity for floodwall footings was analyzed for both drained case using the design drained angle of internal friction of 28 degrees and for the undrained case using the design undrained cohesion of 1000 psf (see Appendix B.4), with the undrained case controlling. The floodwall footings were analyzed as continuous footings 7 to 20 feet wide with a spreadsheet using Terzaghi and Vesic methods. Length to width ratios for the floodwall footings exceed 5, a standard ratio for considering footings to be continuous. Floodwall segments generally run for several hundred feet; the shorter segments are for shorter walls with smaller footing widths. The design bearing capacity is 2000 psf.

7.5. Settlement

Section 7.5 discusses settlement criteria, design methodology, and recommendations.

7.5.1. Design Criteria

EM 1110-2-1913 states evaluation of the amount of post-construction settlement that can occur from consolidation of the embankment and foundation may be important if the settlement would result in loss of freeboard of the levee or damage to structures in the embankment.

The EM states many districts overbuild a levee or berm by a given percent to take into account anticipated settlement both of the foundation and within the levee or berm fill itself. The EM references overbuild of five to ten percent for semi-compacted fill, which is the anticipated degree of compaction for berms.

7.5.2. Consolidation Testing

Consolidation tests (ASTM D2435) were performed on undisturbed samples of foundation soils as part of the planned laboratory testing program. Average consolidation parameters with one standard deviation in the conservative direction were used for design, as discussed in Part 6. New compacted embankment soils were assumed to be relatively incompressible.

7.5.3. Levee and Floodwall Settlement

The maximum consolidation settlement of the clay subgrade soils due to construction of the new levee is expected to be around 3 inches. For predicted levee settlement of less than 6 inches, the Kansas City District does not typically recommend an overbuild.

The maximum consolidation settlement of the clay subgrade soils due to construction of the new floodwall is expected to be around 1 inch. Differential settlement between adjacent monoliths is expected to be less than ½ inch. Based on conversations with EDD-S about the concrete wall and flexibility of the water stop between monoliths, a maximum settlement of one inch is considered acceptable.

7.5.4. Pipe Settlement

Settlement of drainage structure pipes will be evaluated at a future submittal.

7.5.5. Recommendations

No overbuilds or mitigation are recommended for settlement.

7.6. Riverside Slope Protection

This section discusses riverside slope protection for the Upper Turkey Creek FRM Project.

7.6.1. Literature Review

Literature review to be completed for a future submittal.

Future Reference: K:\MissionProjects\civ\turkeycr\505229 Upper Turkey Creek CG\3.0 Project Data & Reference Info\3.4 Background Docs\Historical reports

7.6.2. Method of Analysis

The method of analysis was discussed previously in Section 4.7.

7.6.3. Criteria

Multiple criteria with respect to slope protection can be considered applicable to the Upper Turkey Creek Levee. Regarding the resilience of potentially erodible levee embankment materials, Table 2-5 of EM 1110-2-1601 provides permissible channel velocities for given surface materials and soil types and is presented in Figure 7.7. From this table, a mean velocity of 5 to 8 ft/sec would be assumed to represent an approximate threshold of resiliency for both the current and proposed levee raise, given the riverward soils and maintained sod cover. EM 1110-2-1601 also recommends a W50, weight at which 50% of the stone protection material is less than, (minimum) of 80 pounds for locations vulnerable to theft and/or vandalism. With the urban location of the levee, this recommendation is considered relevant to the project. Given the recommended minimum W50 value, the corresponding D50 value according to Table 3-1 (Figure 7.8 in this document) in EM 1110-2-1601, for a specific weight of 155 pcf, is approximately 12 inches, based upon the relationship D50=D30(D85/D15)0.33, presented in Section 3.7.b. of EM 1110-2-1601, where D85/D15 is assumed to be equal to 1.7. The corresponding D100 value according to Table 3-1 in EM 1110-2-1601, for a specific weight of 155 pcf, and 165 pcf is 21 inches.

EM 1110-2-1601 presents standardized gradations in Table 3-1 having a relatively narrow range in sizes (D85/D15 of 1.4 to 2.2); whereas the stability coefficient for incipient breach for Equation 3-3 in EM 1110-2-1601 is for a D85/D15 range of 1.7 to 5.2. A value of 1.7 was selected due to its placement within the documented range of values. This relationship was used to correlate the D30 (min) value presented in EM 1110-2-1601 Table 3-1 with the D50

(minimum), and corresponding W50 (minimum) value of 80 pounds recommended to address the urban placement of riprap.

Figure 7.7. Table 2-5 excerpted from EM 1110-2-1601.

Table 2-5
Suggested Maximum Permissible Mean Channel Velocities

Channel Material	Mean Channel Velocity, fps
Fine Sand	2.0
Coarse Sand	4.0
Fine Gravel[1]	6.0
Earth	
Sandy Silt	2.0
Silt Clay	3.5
Clay	6.0
Grass-lined Earth (slopes less than 5%)[2]	
Bermuda Grass	
Sandy Silt	6.0
Silt Clay	8.0
Kentucky Blue Grass	
Sandy Silt	5.0
Silt Clay	7.0
Poor Rock (usually sedimentary)	10.0
Soft Sandstone	8.0
Soft Shale	3.5
Good Rock (usually igneous or hard metamorphic)	20.0

Notes:
1. For particles larger than fine gravel (about 20 millimetres (mm) = 3/4 in.), see Plates 29 and 30.
2. Keep velocities less than 5.0 fps unless good cover and proper maintenance can be obtained.

Figure 7.8. Table 3-1 excerpted from EM 1110-2-1601.

Table 3-1
Gradations for Riprap Placement in the Dry, Low-Turbulence Zones

Notes:
1. Stone weight limit data from ETL 1110-2-120 (HQUSACE, 1971 (14 May), "Additional Guidance for Riprap Channel Protection, Ch 1," US Government Printing Office, Washington, DC). Relationship between diameter and weight is based on the shape of a sphere.
2. The maximum limits at the W_{50} and W_{15} sizes can be increased as in the Lower Mississippi Valley Division Standardized Gradations shown in Appendix F.

7.6.4. Analysis Results

Discussion regarding the analysis results and a summary table of the recommended maximum riprap diameters can be found in Section 4.7.2.

7.6.5. Recommended Riprap Gradations

Riprap gradations for the minimum D100 sizes are provided in Table 7.9 based on Table 3-1 in EM 1110-2-1601 (1994) for specific weights of 155 and 165 pcf. Table 7.7.10 and Table 7.11

Table 7.9. Recommended Riprap Weights.

7.6.6. Recommended Bedding Gradation and Thickness

No specific guidance for bedding design is available for levees. General requirements for dams were used. In general, for dams, the gradation of the bedding material should provide for retention of bedding particles by the overlying riprap layer and for retention of the material underlying the bedding layer. Bedding material should generally conform to Equations C-1 through C-3 from EM 1110-2-2300, General Design and Construction Considerations for Earth and Rock-Fill Dams (2004).

Figure 7.7.9. Bedding Gradation Criteria.

$$D_{15B} > 5D_{15E} \quad \text{(C-1)}$$

$$D_{15B} < 5D_{85E} \quad \text{(C-2)}$$

$$D_{85B} > D_{15R}/5 \quad \text{(C-3)}$$

where

D_{15B} = the 15 percent passing the size of the bedding

D_{85B} = the 85 percent passing the size of the bedding

D_{15E} = the 15 percent passing the size of the material to be protected

D_{85E} = the 85 percent passing the size of the material to be protected

D_{15R} = the 15 percent passing the size of the riprap

An intermediate filter layer may be required between the bedding and riprap to prevent washout of the bedding. Bedding layers over erosion-resistant clay materials need not be designed to meet the criteria of Equation C-1 or Equation C-2 but must still satisfy Equation C-3. Each design should produce a specification that defines material sources, gradations, and layer thickness to economically provide the riprap and bedding layers required to protect the embankment.

In addition, the bedding must not be so broadly graded as to be susceptible to internal instability. USBR guidance recommends bedding material be considered internally unstable when its coefficient of uniformity is less than 10 (Design Standards No. 13 Embankment Dams, Chapter 7 Riprap Slope Protection, Section 7.3.7.1, dated May 2014).

EM 1110-2-2300 states that bedding materials over erosion-resistant clay materials need not be designed to meet the criteria of Equation C-1 or C-2 but must still satisfy Equation C-3.

Bedding was sized to be retained by the maximum size riprap of 36 inches. A two-stage filter or geotextile for retaining clay-size embankment particles in the bedding layer is not recommended. The levee is not subject to frequent wave action. The gradient of flow is generally from river to riprap, to bedding, and then to embankment. In addition, the levee embankment will be erosion-resistant compacted homogenous impervious fill and levee and floodwall subgrade soils are generally composed of relatively nonerodable clay material. Bedding compatibility calculations are included in Appendix B.6.

It is recommended that bedding material meet the gradation requirements of Kansas Department of Transportation (KDOT) Stone for Filter Course, Type III Material (see KDOT Specification 1114 [2015]).

The recommended bedding gradation listed by percent finer is given in Table 7.12.

Table 7.12. Recommended Bedding Gradation.

Sieve/Size	Percent Finer
6” (152.4 mm)	100
5” (125 mm)	75-95
2” (50.8 mm)	40-60
3/8” (9.525 mm)	5-25

Based on local practice for levees in the Kansas City District and satisfactory performance history through several high-water events, bedding thickness will be set at six inches.

7.7. Levee System Overtopping Resilience

Overtopping resiliency measures will be considered in a future submittal

7.7.1. Earthen Levee Embankment Overtopping Resiliency

Turkey Creek is too flashy to effectively flood fight, so earthen levee embankment overtopping resiliency will be considered in a future submittal.

7.7.2. New Floodwall

Will be considered in a future submittal.

7.8. Levee Construction Materials

This section discusses levee construction materials.

7.8.1. Borrow Sites

See Part 8 for discussion of borrow material.

7.8.2. Fill Materials

On-site soils from required excavations, imported soils from provided borrow sites, or off-site borrow sites obtained by the contractor to be used as fill material shall be free of muck, frozen material, excess moisture, organic material, topsoil, rubbish, construction debris, chemical contamination, and rock larger than three inches. On-site soils from required excavations which are suspected by odor or appearance of petroleum contamination shall be handled in accordance with project specifications. Prior to placement in any excavation or embankment, fill material imported from provided borrow sites or borrow sites obtained by the contractor shall be verified to be free of chemical contamination by performing the environmental tests listed in the project specifications.

7.8.2.1. Impervious Fill

Impervious structural fill shall be used in the levee embankment and for backfill of any excavations within the levee critical area (within 500 feet of the landside toe and within 300 feet of the riverside toe of the levee or floodwall), except where otherwise specified. This includes backfill (other than pipe bedding) for installation or modification of drainage pipes and drainage structures. This material shall consist of satisfactory impervious material classified as lean clay (CL) or low plasticity silt (ML) in accordance with ASTM D2487. High plasticity clay (CH) and high plasticity silt (MH) are not suitable for backfill around structures due to their expansive properties. Sandy materials are also not acceptable in these areas as excavations for drainage structures extend into the natural blanket materials in areas where there is no filter zone. It is anticipated that impervious structural fill will be obtained from the required excavations or approved borrow sites.

7.8.2.2. General Construction Considerations

Grading areas should be cleared, grubbed, and stripped as outlined in the project specifications in preparation for fill placement. Areas to receive fill should be scarified to a depth of 6 inches and moisture conditioned. Levee and stability berm fill should be compacted by not less than four passes of compaction equipment suitable to the type of material being placed and shall be compacted to a minimum of 95 percent of the maximum dry density as determined by the contractor in accordance with ASTM D698.

8.0. BORROW AREAS

Soil fill for construction will be obtained from a combination of required excavations and offsite borrow sites.

The City of Merriam has identified two potential borrow sources for this project in Merriam, Kansas, one at Ikea Way and W 62nd Terrace in Merriam and one at W 50th Terrace near Grant Street. Subsurface investigation at the Ikea Way borrow site (which is unlikely to be available when this project resumes) is discussed in Appendix A. Subsurface investigation at the borrow site on W 50th Terrace is discussed in Part 6. Aerial photos and boring logs for both sites are included in Appendix A.

Construction of a multistory apartment building with a below grade parking garage is planned for the site on Ikea Way. Excavation at the site was planned to begin in December 2025 with any excess material stockpiled. The City of Merriam will inform USACE of how much material is stockpiled for use as borrow. As detailed in Appendix A, based on the visual classifications given in the boring logs and on the limited laboratory testing, the material is assumed to be suitable for use as impervious fill. Based on the current understanding of grading plans for the site, it is unclear if there will be a significant amount of borrow available from this site. It is unlikely that this borrow would be available long-term if this project is delayed.

No development is currently planned for the site on W 50th Terrace. This site is a relatively level open lawn area with trees on the outside. The boring logs indicated lean clay soils and gravelly fill. The gravelly fill is not suitable for use in levee embankments. The areal extent of the fill soil has not been determined. Laboratory testing and final boring logs are included in Appendix A.

If it is determined that additional or alternative borrow sites are required as the design progresses, USACE will work with the City of Merriam to identify additional sites. Otherwise, the construction contractor would need to find a commercial source.

8.1. Estimated Borrow Quantities

Based on the current design, roughly 15,000 – 20,000 cubic yards of levee fill is needed from another source for the project. This quantity assumes roughly half of the material excavated from the detention basin and any excess material from floodwall construction will be suitable material to use as levee fill.

This page was intentionally left blank for duplex printing.

9.0 STRUCTURES

9.1 General Design

This section presents the structural design criteria and assumptions for the Upper Turkey Creek flood management project, the primary function of which is flood protection in the Merriam, Kansas, area. Structures proposed for this project include floodwalls (soil-founded floodwalls$ and I-walls), potential retaining walls at properties of interest to the City of Merriam, a gatewell at the detention basin, and outfall structures and flapgates where stormwater conduits discharge into Turkey Creek.

9.1.1 Materials

9.1.1.1 Material Weights

Table 9-1. Design Material Unit Weights.

Material	Unit weight (pcf)
Water	62.4
Concrete	150
Steel	490
Aluminum	170
Riprap	130
Gravel	125

9.1.1.2 Material Design Strengths

9.1.1.2.1 Steel

Steel piles and sheet piles are ASTM A709 Grade 50. Structural steel shapes; Channels and angles are ASTM A36, HSS round and rectangular shapes are ASTM A500 and pipe sections are ASTM A53 Gr. B. For steel plates and bars, a minimum strength of ASTM A36 steel with a yield stress of 36 ksi is required. Where materials are required to have higher strengths, the drawings and specifications will clearly notate the changed ASTM strength designation for the material.

9.1.1.2.2 Aluminum

If aluminum is used for parts and components, or miscellaneous metals scope, it will be extruded shapes of either grade 6061 or 6063 T3 or T6 as applicable and as outlined by the drawings or specifications.

9.1.1.2.3 Stainless Steel

Stainless steel may be used for embedded plates in concrete. Stainless steel will be ASTM A240 grade 316 unless otherwise called out in the plans and specifications. Stainless steel grades and type are noted on the design drawings and in the specifications.

9.1.1.2.4 Reinforced Concrete

Unless noted otherwise in the drawings or specifications, concrete and rebar strengths used for design were f'_c=4,500 psi and f_y=60,000 psi. the reinforced concrete used will adhere to the requirements in EM 1110-2-2104 and EM 1110-2-2502 for rebar detailing and requirements for minimum and maximum areas of steel.

9.1.1.2.5 Existing Concrete

When information was not available for the design strengths for the existing concrete and rebar, the following values will be used for analysis: f'_c=3,000 psi and f_y=40,000 psi. The assumed existing concrete strengths are based on values in ASCE 41, *Seismic Evaluation and Retrofit of Existing Buildings*.

9.1.1.2.6 Soil Parameters

Table 9-2. Typical Soil Properties.

Property		Embankment	Foundation Soil
Saturated Unit Weight		120 pcf	115 pcf
Effective Unit Weight		57.6 pcf	52.6 pcf (buoyant weight)
Short Term/Undrained	Internal Friction Angle	0°	0°
	Cohesion	1,000 psf	1,000 psf
Long Term/Drained	Internal Friction Angle	28°	28°
	Cohesion	0 psf	0 psf
Allowable Bearing[1]		2,000 psf	

[1]FS=3.0 per ECB No. 2017-2. Includes water pressure influence due to flood loading. Refer to Appendix B for allowable bearing calculations.

9.2 Design Loads

9.2.1 Flood Loading

9.2.1.1 Design Flood Protection Requirements

Unless noted otherwise, floodwalls, gatewells, I-walls, conduits, bridge parapets included in flood protection, and outlet works structures were designed to the 100-year return period flood (0.01 AEP) elevation. The required 100-year (0.01 AEP) top of protection elevations were rounded up to the nearest inch. Tops of new floodwall stems do not have stepped elevations. Where needed, a single monolith with a sloped top accommodates the difference of about 6 inches in elevation from the required protection level and the top of the wall. Sloping transitions are made at least 2 ft from the end of the monolith section and maintain a 1 on 4 slope, the change in elevation is developed over a 2 foot run along the top length of the wall monolith. Sloping the protection elevation in lieu of a stepped transition at the joint was chosen so that during future inspections it could be readily observed if there were settlement issues between the two monoliths at the joint.

9.2.1.2 Hydraulic Loading Conditions

Three levels of performance were evaluated; serviceability, strength, and stability. Applicable load conditions for the flood protection were the *usual* and *unusual* load cases. The floodwalls are designed for a protection from the 100 year event (0.01 AEP); therefore, the Extreme loading conditions with a return period of 700 years do not apply to the design. The usual load flood loading applied to the structures is based on a WSE generated by a 10-year return period (0.1 AEP) flood event, and the unusual loading condition is generated by a flood event associated with the 100-year return (0.01 AEP), which is the top of protection pool.

The Serviceability loading condition considers the loading from the 100 year event as well. These loads are then scaled by a single load factor from Table 3-4 of EM 1110-2-2104 (2025 revision). EM 1110-2-2104 outlines design of Reinforced Concrete Hydraulic Structures (RCHS) using the Serviceability requirements as well as Strength design requirements. Reference attached calculations for the 12 foot tall T-wall that shows that the controlling loading for the T-wall systems will come from the Serviceability loading conditions. The remaining calculations for other T-Wall heights as well as the calculations for the I-wall materials are abridged to include only the Serviceability requirement checks since they govern the loading to the wall. The calculations package for the T-Walls shows that the serviceability checks will govern the design of the wall over the strength requirements, this is shown for the wall section that has the longest section of the stem that is exposed.

Stability limit states were used to satisfy stability requirements under drained and undrained loading conditions. Analyses are performed using unfactored loads to check stability failure modes described in EM 1110-2-2100 and to compute bearing pressure exerted on the soil as well as the uplift pressures on the foundation according to EM 1110-2-2906. The unfactored moments, shears, and thrusts on the foundation were then multiplied by the appropriate load factor to determine design forces used to establish the required section properties.

9.2.2 Impact Load (debris)

The inlet structure sizes which distribute water to this reach of Upper Turkey Creek will keep vegetation debris exposure to smaller sized logs. Mostly medium-sized, partial trees have the capacity to enter the waterway. It is anticipated that debris other than trees/logs will also be present, however within this reach of Turkey Creek, debris must enter the waterway by means of constricting culverts and concrete box culverts, so the size of debris is expected to be no larger than trees/logs. The current design of the left bank may have lengths of the alignment that are unprotected by levee or floodwall and thus would allow for debris to enter the channel. The area to the west of Turkey Creek is highly developed with minimal large vegetation. Likely only man made debris would enter the channel.

USACE criteria for debris loading is outlined in EM 1110-2-2502 in paragraph 6.12.3. the manual allows for a typical linear loading condition between 100 and 500 pounds per foot at the top of the flood protection level. For the T-walls of this project the Impact loading for the majority of the walls was limited to 100 pounds per foot at the top of the wall except where the angle of attack between the flow and the wall is steeper. This was applied at locations like the confluence of Turkey Creek and the tributary located at the upstream end of the project as well as the opposite bank of the Quaker Creek outfall. During the design, a hydraulic analysis was conducted and the flow vectors through this area show that even where the confluence of the tributary and Turkey Creek meet, the flows are still largely parallel to the face of the floodwalls. This analysis and additional descriptions are presented in the ‘Justification’ calculations provided at in the appendix of this report.

9.2.2.1 Debris for Faces Impeding Flow

The faces impeding flow include the upstream parapet faces on Johnson Drive, Merriam Drive Bridge structures, upstream faces of gatewells, and buttress structures perpendicular to the flow, which will support dam faces on walls above inlet structures which are parallel to the flow. The debris loads included in the design of these structures are point loads due to aberrant log impacts or a small uniform load of 500 pounds per linear foot (PLF).

The impact loading to impeding faces was chosen to be the maximum recommended loading from EM 1110-2-2502 where the water flow is perpendicular to the flow of water. This loading was compared to the loading calculated per ASCE 7-16 C5.4.5, *Impact Loads*, assuming 1,000 pounds contribute to the impact load. This is equivalent to a 12-inch diameter, 20-foot-long log, which is believed to be representative of approximately the largest log or tree expected in the river during a flood. This force considers either stopping the full impulse momentum of a 1,000-pound log hitting perpendicular to the structure or a portion of a larger log that hits at an angle. The velocities of the water flowing parallel to the channel were taken based on the HEC-RAS output at each specific structure's location. The resulting point load or the general line load is comparable to the suggested 500 pounds per linear foot from the Engineering Manual and thus the suggested loading is applied at the static WSE as a companion to the primary hydrostatic flood load.

9.2.2.1.1 Debris for Faces of Structures Not Impeding Flow

These locations include the floodwalls parallel to the channel and the vertical walls of the outfall structures as well gatewell faces other than the upstream side. For these structures, it is likely that debris impacts will be glancing, and by the rationale provided above the Impact loading is a minimum of 100 lbs per foot at the top of the wall. Reference also the section 9.2.2 discussing the impact loading from debris.

9.2.2.1.2 Debris for Pedestrian Bridges

The two pedestrian bridges located inside the project limits were evaluated for a horizontal debris impact loading of concentrated loading of 1,375 pounds based on calculations provided. The location of the impact loading was applied at the walkway level, and where the shear and moment were maximized. The loading was also increased by a load factor of 1.4 for unusual loads as described in Engineering Manual (EM) 1110-2-2502 and EM 1110-2-2107. The unfactored loading for impact was derived from the ASCE 7-16 commentary for flood impact loading. Section C5.4.5 outlines the analysis of debris striking structures located in floodwaters. Reference attached calculations package for specific considerations, impact loading based on 1,000 pound load striking the side of the bridge traveling at 1.6 feet per second and impacting the bridge for 0.03 seconds. The velocity and impact duration are based on the commentary from section C5.4, and the Maximum Response Ratio is based on the commentary of section C5.4 as well as section 12.8.2 of ASCE 7-16. From Equation 12.8-7 the variables are taken from Table 12.8-2 for 'All other structural systems.'

9.2.3 Ice Loads

While ice will occur in Turkey Creek during the coldest winter months, ice loads impacting structures are not anticipated to occur concurrently with a flood event high enough to load the stem of the structures. The historical flood season/period of record occurs in the spring and summer and thus ice loads will not be included.

9.2.4 Wave Loads

The EM 1110-2-2104 and EM 1110-2-2502 state that wave loads are computed as described in EM 1110-2-1100 accounting for the location of the structure, the characteristics of the hydraulic loading and the site conditions. Wave loads acting on these floodwalls will be insignificant because the fetch lengths are too small to generate a significant wave height. Wave loads are considered inconsequential and ignored in the floodwall design calculations.

9.2.5 Wind Loads

Wind loads were determined in accordance with ASCE 7-16. Section 9.2.5.1 lists the parameters. Wind loads are applied as vacuum pressures to the back side of the stems of floodwalls when serviceability is considered. The floodwall stems were not assessed for wind loading without the presence of water, indicative of conditions where the walls are not loaded with floodwater and are loaded by wind pressure as this loading condition is far lower than the Unusual loading condition and thus by inspection is acceptable.

- Exposure Category: C

9.2.5.1 Applied as a primary load:

- Wind Speed: 122 mph (Risk Category (RC) IV, MRI=1,700 years)
- Resulting pressure*: 30.4 pounds per square foot (psf)

9.2.5.2 Applied as a companion load with flood or construction loads:

- Wind Speed: 88 mph (ASCE 37-14, RC II, 0.8 Construction Factor)
- Resulting pressure*: 15.8 psf

*For continuous wall: K_z=0.85, K_{zt}=1.0, K_d=0.85, K_e=1, G=0.85, C_f =1.3

9.2.6 Construction Loads

The project specification for levee construction requires approved hand operated compactors and a maximum lift of four inches within four feet of structures. Outside of four feet, rolling compaction equipment and a maximum lift of eight inches is allowed. Construction surcharge loads are based on applicable construction equipment but not less than a generalized load of 250 psf. Construction surcharge loads are applied to both the driving side and the resisting side of the wall sections. Refer to Appendix D for the construction load used in each feature specific calculation.

9.2.7 Surcharge Loading

The majority of the floodwalls will not be loaded with surcharge loads from the land side that are significant enough to be considered as part of the design. Two specific locations, both along the right bank of the creek were analyzed with surcharge loading to the toe of the foundations. The first location on the right bank is the area where the floodwall will be adjacent to Merriam Drive, located south of the intersection of Johnson Drive and Merriam Drive. This location will experience heavy wheel loadings from the northbound and southbound lanes of Merriam Drive. Loads considered in this area were taken from the AASHTO LRFD manual and applied the approximate distance away from the foundation.

The second location along the right bank where surcharge loads were considered is located upstream of the first location at approximate creek station 34+00. Through this location there are several industrial facilities that store building materials near the proposed alignment of the floodwalls. This 10 foot tall wall was also checked for surcharge loading because during a visit to the site it was noted that one of the facilities was storing pallets of shingles near the wall. Due

to the weight of the building materials and the lack of space behind the facility the wall's foundation was checked for strength using the additional surcharge loading.

9.2.8 Seismic Loads

- Risk Category: IV
- Site Class: D–Stiff Soil (see 6.9.6)

Table 9-3. Seismic Parameters.

Notation	Value	Description
S_s	0.095	MCE_R ground motion for 0.2 second period
S_1	0.069	MCE_R ground motion for 1.0 second period
S_{MS}	0.152	Site-modified spectral acceleration value
S_{M1}	0.165	Site-modified spectral acceleration value
S_{DS}	0.101	Numeric seismic design value at 0.2 second spectral acceleration
S_{D1}	0.11	Numeric seismic design value at 0.2 second spectral acceleration

The inertial mass of this T-wall when accelerated by the design acceleration (SDS) produces a lateral force similar to the wind load applied to this structure (30 psf). The total lateral force using the equivalent lateral force procedure for a 10-foot stem wall is approximately 34 psf, or 340 pounds applied at the center of gravity of the 10-foot stem. This seismic response force produces less overall force on the T-wall than the static hydraulic force applied during the 0.01 AEP design load. The base and foundation of the T-wall is not included in the overall inertial mass since it is below the ground surface as seismic base shears is only distributed to mass above the base. The base of this structure can resist higher shear loads without sliding from applied static hydraulic loads, therefore these structures will not slide due to seismic loads.

9.3 Design Criteria

9.3.1 Stability

Refer to EM 1110-2-2100 (2005) Chapter 3 and B-3.c and ECB No. 2017-2. Table 9.4 shows these load cases that apply. From inspection of these load cases and considering the descriptions in EM 1110-2-2100 B-3.c (2), the only case that needs to be addressed in the stability analysis is the unusual case with water to the top of wall. With the Infrequent Flood (IF) and the Maximum Design Flood (MDF) probability of occurrence and wall loading equal, case I1 and case I2 are identical. Load Cases I3a and I3b are seismic load cases coinciding with the mean annual non-flood operating conditions. The mean annual river stage is below the floodwall; thus, the load cases need not be considered (see EM 1110-2-2100 B-3. c (2) (c) and (d)). Additionally, with site-modified ground accelerations less than 0.2g, seismic demand will not be greater than demand from the MDF. Load case I4, construction loads, will not control as construction loads near the wall are limited to 250 psf vertical load, which is much less than the design and allowable bearing pressures.

Table 9-4. Inland Flood Wall Stability Load Cases Adapted from EM 1110-2-2100 Table B-4.

Load Case	Loading Description	Classification
I1	Infrequent Flood (IF)	UN
I2	Maximum Design Flood (MDF)	UN/E
I3a	Coincident Pool+OBE	UN
I3b	Coincident Pool+MCE	E
I4	Construction	UN

Sliding (EM 1110-2-2100 Table 3-2) minimum FS is 1.5 for all applicable cases. For this use the T-walls are assessed as critical structures with ordinary site conditions and are loaded with the Unusual Loading Condition category.

Overturning (EM 1110-2-2100 Table 3-5) requires a minimum of 75 percent of the base be in compression for all applicable cases. The applicable cases for this analysis is the Unusual Loading Condition.

Allowable Bearing Capacity (ECB 2017-2 and EM 1110-2-2100) minimum FS for critical structures for Usual case is 3.5, for the Unusual case is 3.0, and for the Extreme case is 2.0. For this project, top of floodwall loading corresponds to the Unusual Load Condition category for a critical structure and a FS of 3.0 is used in the analysis.

9.3.2 Floodwall Bearing Capacity

Soil parameters were provided to the structural engineers for both the soil against and below the soil-founded floodwalls for all project soil-founded floodwall locations. The factors of safety shown in Table 9.5 from ECB 2017-2 Table 2 were used in the structural calculations to obtain allowable bearing capacity values for the various load cases.

Table 9-5. Stability Factors of Safety for Critical Structures.

Category	Usual Minimum FS	Unusual Minimum FS	Extreme Minimum FS
Bearing on Soil	3.5	3.0	2.0

The Unusual case FS for bearing governs the design for floodwalls in this project. The ultimate bearing capacity for soil was determined using EM 1110-2-1905, Equation 4-16 and Meyerhof parameters. Safety factors were applied to the ultimate bearing capacity measured, and not the estimated allowable bearing capacity. The allowable bearing capacity may be estimated according to EM 1110-2-1905 equation 1-2a, where the ultimate bearing is divided by an appropriate FS according to soil type and loading conditions. Section 4-3 of the EM allows for allowable bearing capacity to be estimated with a FS of 2 for cohesionless soils, and a FS of 3 for cohesive soils. The unusual case FS, and the allowable estimated-safety FS for cohesive soils were not taken together.

9.3.3 Concrete Design

EM 1110-2-2104 defines the design requirements for Reinforced Concrete Hydraulic Structures (RCHS) and is the governing criteria for the design of floodwalls, gatewells, and headwalls. The loading requirements in Chapter 3 will be applied per 3.8-Mandatory Requirements, the minimum loading cases in Appendix E shall be satisfied. EM 1110-2-2104 Table E-3 for Inland Floodwalls are analogous to EM 1110-2-2100 paragraph B-3 c and Table B-4, and the

controlling load case is determined similarly as was done for stability. Top of wall hydraulic loading controls for strength design, and temporary loads of seismic and construction loads do not control. EM 1110-2-2104 allows for the design of the T-walls using the strength design methodology, the serviceability stress design or the alternate serviceability stress design (single load case) methodology. Reference the attached load calculations for the derivation, it is shown that the single load case for the loading on the stem with the tallest exposed length of stem governs the design. The following designs for the T-walls does not include the strength design methodology nor the serviceability stress design. Loads applied using the single load case will be as described in Section 9.2 of this DDR, and applied as they are appropriate. Refer to the calculations package in the Appendix D of this report for the specific application. A load factor of 1.6 for the Unusual Case is the controlling case for concrete design for the T-wall structures on this project.

Table 9-6 provides typical reinforced concrete design parameters.

Table 9-6. Reinforced Concrete Design Parameters.

Design Parameter	Hydraulic Structures	Other Civil Works
Concrete design strength	f'_c=4,500 psi typical	
Reinforcement ASTM A615 Grade 60; ASTM A706 Grade 60 if welding is required	f_y=60,000 psi	
Strength reduction factor for shear ACI 318, Table 21.2.1	φ_v=0.75	
Strength reduction factor for flexure ACI 318, Table 21.2.2	φ_b=0.90	
Factor for equivalent rectangular compressive stress block ACI 318, 10.2.7.3	0.85-0.05 (f'c-4,000)/1,000=0.825	
Maximum flexural reinforcement without detailed analyses of the serviceability limit states EM 1110-2-2104, 3.5; EM 1110-2-2502 9-8b (3)	$\rho \leq 0.25\ \rho_b$ where ρ_b=balanced reinforcement	$\rho \leq 0.50\ \rho_b$
Minimum flexural reinforcement EM 1110-2-2104, 3.5.1.4 ACI 318 Sec. 9.6.1.2	$\rho > 3\sqrt{f'_c}/f_y$ and $\rho > 200/f_y$ or one-third greater than the reinforcement required by the structural analysis	
Minimum longitudinal temperature and shrinkage reinforcement EM 1110-2-2104, Table 2-3; ACI 318 Sec.24.4.3.2	$\rho \geq 0.0030$ (control joints<30 feet); $\rho \geq 0.0040$ (control joints 30–40 feet); $\rho \geq 0.0050$ (control joints >40 feet)	$\rho \geq 0.0018$
Minimum transverse temperature and shrinkage reinforcement EM 1110-2-2104, 2.9.1	Based on longitudinal requirements if the primary reinforcement is less than required for temperature and shrinkage.	
Maximum temperature and shrinkage reinforcement EM 1110-2-2104, 2.9.2	#9 bars at 12 inches in each face	

Design Parameter	Hydraulic Structures	Other Civil Works
Minimum concrete thickness EM 1110-2-2104 3.7 EM 1110-2-2502 6-3	12 inches	8 inches (H≤8 feet); 12 inches (H>8 feet)
Minimum concrete cover EM 1110-2-2104, Table 2-1; EM 1110-2-2502 9-4	ACI 318 §20.6.1.3 (T≤12 inches); 3 inches (12 inches<T<24 inches); 4 inches (T≥24 inches); 4 inches for unformed surfaces in contact with foundations	ACI 318 Sec. 20.6.1.3

9.4 Floodwalls

9.4.1 I-walls

I-walls were considered as a potential cost-effective alternative to T-walls in areas where lower floodwall heights were required and available right-of-way was limited between existing structures and the creek channel. The analysis focused on determining the required penetration depth of the sheet piling to account for rotational stability for various wall heights corresponding to the above-ground heights of the six different floodwall geometries.

The existing soil conditions indicate a maximum I-wall height (exposed stem height) of 7 feet per EM 1110-2-2502. In some areas, the required penetration depth needed for rotational stability was not available due to shallow bedrock. Reference Part 07 for expanded discussion on the computations for the I-walls. Prior to finalization of the locations for the I-walls, field verification and exploratory drilling will be conducted to ensure that the required penetration is available. If the required penetration is not available due to shallow bedrock or other issues, the I-walls in that area will be installed by trenching to the required depth, and backfilling around the sheet pile with flowable fill. It is recommended that field verification be performed during design to allow for adjustments as needed at specific locations. The analysis of underseepage and global slope stability for the I-walls is addressed in Part 07 of this report.

I-walls are also planned as part of the transition from floodwall to levee system as outlined in EM 1110-2-2502, Chapter 12, Figure 12.1, except that the floodwalls for the scope of this project do not include Z-pile sheet wall sections. Figure 12.2 shows the plan view of the sheet pile section with respect to the levee, I-wall and T-wall. Since the sheet pile is not intended to be carried into the heel of the T-wall, the variance from this plan view will include not having the stem wall stub to accommodate the slip joint between the I wall and the T-wall. This plan will be altered to include a portion of the heel of the T-wall that turns and comes back toward the center line of the wall to cut off the seepage path between the T-wall's foundation and the sheet pile cutoff of the I-wall. This is done to provide a continuous and uniform barrier that lengthens the seepage path under the foundation of the walls.

The connection of the sheet pile and the I-wall concrete section is outlined in Section 9.8 of EM 1110-2-2502. The intent of the design is that the I-wall sections that are exposed, above ground level, would have the same stem thickness as the T-wall sections. Because of the required Z-pile shape depth, the transition portion of the I-wall that contains the Z-pile will need to be a minimum of 2 and a half feet in thickness to accept the pile profile, the reinforcing steel, and the required 6 inches of concrete cover over the outside of the pile. The intent is to have the I-Wall taper down each face under the levee embankment slope so that when the wall is exposed it matches the stem thickness of the T-walls at one and a half feet in thickness.

9.4.2 T-wall Floodwall

Refer to Sections 9.3 and 9.3.2 for typical design loads and criteria governing the T-wall design. In addition, floodwalls and retaining walls are designed according to EM 1110-2-2502.

T-wall sections were selected based on required height from ground level and required cover to provide frost depth protection and stability. The USACE computer program CTWALL was utilized to analyze each of the wall locations. Locations for analysis were selected by locating the position on stretch of walls of similar height where the stem height above ground on the riverine side was the greatest. CTWALL files were created for each of these locations, and the output files loaded into an Excel workbook where the summarizing information could be read to the 'Wall Data' sheet. This sheet contains information on the soil geometry, wall dimensions, water surface elevations used for analysis, calculated factors of safety for stability and loads computed from each analysis. The table from the 'Wall Data' sheet is then imported into the MathCAD calculations for the stability calculations for the wall sections and the strength calculations for the stem, foundation and reinforcement detail for the wall sections. The wall sections that were evaluated were the tallest stem section, as measured above the ground surface, of the wall type considered.

Reference section 9.2 for discussion on loading criteria and methodology for the analysis conducted. The analysis of underseepage and global slope stability for the T-walls is addressed in Part 7 of this report.

9.4.3 Secant Pile Walls

During the design process the alignment on the right bank south of Johnson Drive bridge was moved away from the existing block walls and close to the existing structures along the right bank. Real Estate analysis showed that acquiring these properties would be costly. It was determined that we should investigate the use of secant piles that could be built without large amounts or lateral excavations along the alignment through this area. It was preliminarily determined that the piles would need to be approximately 3 ft in diameter to resist the loading applied and support the wall system placed on top of the secant pile. The preliminary design of the secant pile floodwall involved casing the secant pile wall to the existing ground surface elevation and using the secant wall as the foundation supporting the stem wall.

During the preliminary design of the secant pile walls it was determined that the cost of construction would be the main driver for limiting the use of secant pile walls throughout the project. The Project Team also held discussions with the Construction Division and even met on the site where the proposed secant walls would be located. Based on the discussed construction methods for both T walls and secant pile walls the team thought that construction of T walls would be challenging but not improbable enough to justify the high cost of installing the secant pile wall type. These conversations, and the resulting decisions were communicated up the vertical command.

Design considerations for the secant pile wall were taken from limited experience with constructing these wall types. Previous design examples from foundations that were used for pump houses on Argentine and the Interceptor design used for lower Turkey Creek were analyzed. It was discussed that the secant piles would form the foundation for the floodwalls, and would not extend to the full height of the required flood protection. This was determined based on the understanding of the construction method used to install secant pile walls, where the surrounding ground and subsurface are used as the forms for the drilled shafts, both primary and secondary. For these pile profiles to be extended to the top of protection circular false work would have to be provided, creating additional constructability constraints. Because the secant pile type foundation would be continuous, another limitation would be the length of consecutive

runs of this wall type. The secant pile foundation would need to be rigidly connected to the floodwall extending up to the level of protection, and thus would create lengths of floodwalls that would need to be critically analyzed for temperature and shrinkage stresses as they would not have construction or contraction joints at standard 20 foot lengths similar to other wall types.

9.5 Drainage System Structures

Gatewell and manhole designs will meet the strength and stability requirements in Section 9.3.2. The closure, or gate, configuration requirements for drainage structures are defined in EM 1110-2-2902 Table 9-1. For a fast-rising stream, Table 9-1 requires one passive closure for pipe diameters less than 36 inches and one passive and one active closure for pipe diameters 36 inches and larger. As discussed in Part 2, the PDT is pursuing a waiver to allow the use of one passive gate or flap instead of one passive and active gate (sluice) due to the flashy nature of Turkey Creek and the very limited time allowed for personnel to close a sluice gate. Refer to Part 2 for further discussion of the deviation from EM 1110-2-2902 Table 9-1.

9.5.1 Pipes Less Than 36 Inches

Riverside concrete outlet structures with flap gates will be constructed to meet the closure requirements of EM 1110-2-2902, Table 9-1.

9.5.2 Pipes Greater Than 36 Inches

With the waiver to remove the second closure structure on pipes larger than 36 inches, the outfall structures for the pipes that are larger than 36 inches in diameter will be similar to the outfall structures for the pipes with diameters less than 36 inches. Where a levee embankment is crossed, a flap gate and outfall structure will be provided on the riverine side of the levee. Reference structural detail sheets, and schedule for outfall structures for their size and location.

9.5.3 Existing Triple 7-foot-by-7-foot Reinforced Concrete Box at Station 38+70 (Quaker Creek)

Sheet SA-300 to SA-302 shows a concept design to construct a riverside gatewell/headwall structure with single flap gates at the existing triple 7-foot-by-7-foot RCB drainage structure. The headwall will be designed using the loading requirements described in Section 9.3 and the stability and strength requirements in Section 9.3.2. The location of the structure is limited by the adjacent street and sidewalk, limiting the extent of new conduit located behind the headwall of the structure. The wingwalls of the structure extends riverward relative to the upstream and downstream floodwalls and are located below the protection pool and upstream of the confluence of Quaker Creek and Turkey Creek. The structure will transition to T-walls on either side of the new box and the foundations of the T-wall will tie into the exterior walls of the gatewell structure. If it is determined that the bedrock in this location is deep enough that a I walls can be supported through this section then the T-walls juxtaposed to the box structure could be replaced with I walls. The advantage of using I-walls through this location would be the absence of the foundation for the wall, which would interfere with the wingwalls of the structure but would still be adequate.

9.5.4 Detention Basin Inlet and Outfall Structures

The inlet and outfall structure for the detention basin located near the Merriam Farmer's Market location are detailed on sheets SB-300 to SB-302. The intake structure is approximately four foot by twelve foot in cross section and five feet tall. The structure has a low flow opening on the back side that is 9 feet and 2 inches by one foot in height that allows the detention basin to drain during storm events that do not provide enough

rainfall to overtop the structure. The structure is open topped to allow for maximum drainage during larger events and is covered with a grating top that has the maximum standardized opening size. The grating will span in the short dimension across the top of the box so loading will not be an issue to the top of the structure, and the end panel can be removed should access to the inside of the box be required for maintenance. The front face of the intake structure is to be connected to two 48 inch diameter pipes. During design it was determined that the two 48 inch pipes would require a smaller intake structure and narrower outlet structure than the alternatives that were explored. The other pipe configurations that were considered for the detention basin were an arc section 54 inches by 88 inches and a box section that was 4 feet by 8 feet. Both of these sections were excluded for either their geometry or their cost. They would also have required that customized flap gates be fabricated for the outfall structures. The 2 side by side 48 inch pipes provide the required cross sectional area required to meet demand and would allow for standardized flap gates to be used on the outfall structure.

9.6 Bridges

9.6.1 Merriam Drive Bridge at River Mile 2.625 (Reach 3b-1)

During the feasibility study, a recommendation was made of adding 4.5 foot-to-6.0-foot-tall parapet walls on each side of the bridge as flood protection. The design of taller parapets on both sides of the bridge was analyzed, and results showed buoyancy forces exceeded the weight of the bridge. It was proposed that the bridge be raised 2.0 feet to an adequate elevation (909.4 feet) to prevent the buoyancy forces from lifting the bridge. This raise provides a FS against floatation of 1.51. A KDOT standard 180-foot slab bridge was proposed to replace the existing bridge. This proposed bridge will use shorter parapet walls as part of the flood protection system. As part of the new bridge design, new bridge piers are being proposed to overcome a current design issue associated with poor pier alignment in the channel, which currently impedes flow. Scour effects around bridge footings and side slopes will be considered in this design.

9.6.2 Johnson Drive Bridge at River Mile 3.058 (Reach 3b-1)

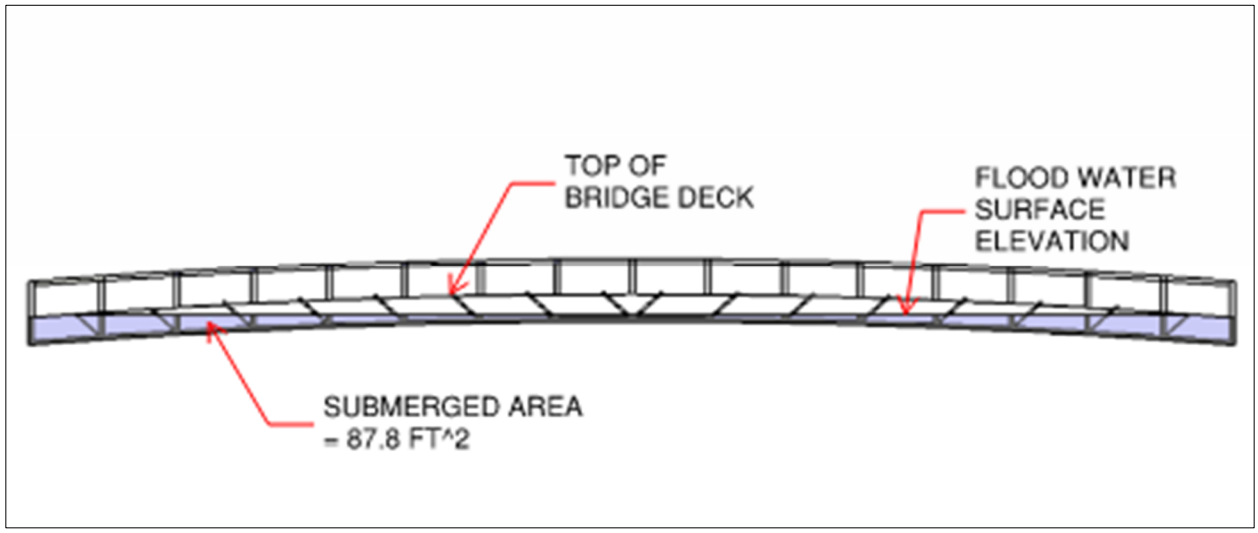
HNTB has provided a conceptual level plan to demolish and replace the existing bridge structure and substructure of Johnson Drive Bridge with a concrete fixed frame bridge as well as raising the roadway elevation of the bridge and widening the channel to the west of the creek centerline. Bridge realignment work will also require that the roadway of Johnson Drive to the west be elevated to a point where it ties into the existing profile elevation approximately 200 feet to the west of the abutment of the new bridge and elevation of the intersection of Merriam Drive and Johnson Drive would also raise approximately one and a half feet causing elevation increases approximately 300 feet east of the abutment of Johnson Drive as well as 200 ft north and south on Merriam Drive.

9.6.3 Farmer's Market Pedestrian Bridge at River Mile 2.875 (Crossing #5 As-Built Drawings) Station 85+10.2

The Farmers Market Pedestrian Bridge was analyzed for stability. The WSE reaches the bridge deck, and the bridge connection to the foundation was analyzed for capacity. Based on drawings of the bridge structure received from the City, the anchors were modeled and analyzed using Hilti's Profis software. Reference the calculations provided in Appendix D of this

report for additional detail, but for the Atlas 14 loading conditions the anchors and bridge connection are adequate to resist the flood loading.

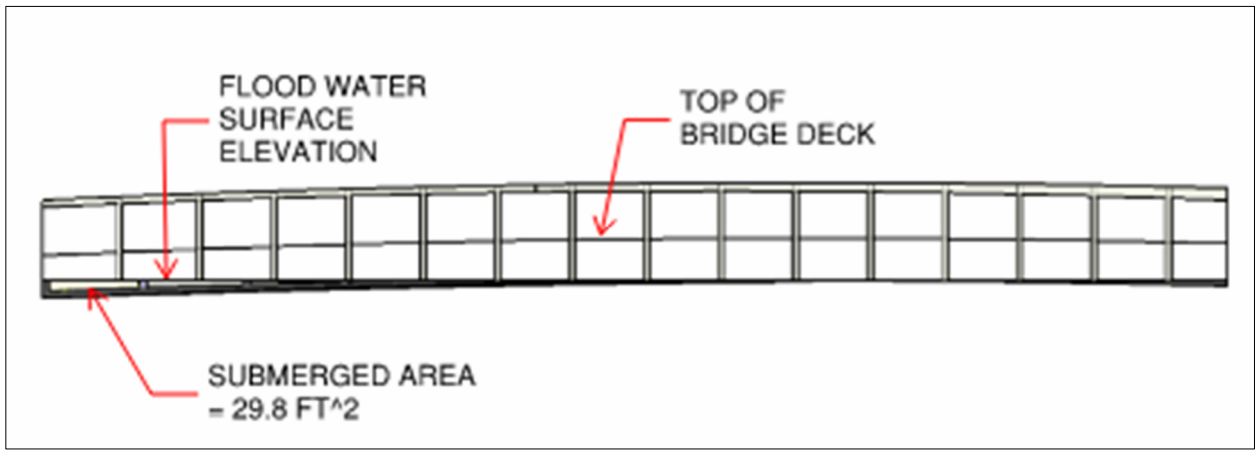
Figure 9.1. Cross Section of the Merriam Marketplace Bridge.



9.6.4 Pedestrian Bridge at River Mile 3.57 (Crossing #2 As-Built Drawings) Station 49+72

The Southern Pedestrian Bridge, Shawnee Mission Parkway Bridge (SMP) was analyzed for stability. The WSE reaches the bridge deck, and the overall shape of the bridge displaces water as would a bridge with closed parapets. Reference calculations provided in Appendix D of this report for additional information. Anchors for the bridge were assessed using Hilti's Profis software and it was determined to have adequate strength to resist the flood loading.

Figure 9.2. Cross Section of the Shawnee Mission Parkway Pedestrian Bridge.



10.0. CIVIL

10.1. Utilities

Existing pipelines crossing the levee that do not meet current USACE criteria in EM 1110-2-2902 will be replaced with pipelines that are compliant. If feasible, all utilities should be located outside of the influence zone. The influence zone is identified as the 15-foot distance from the toe of the levee or the face of the floodwall stem on both the riverside and landside. Existing pipe strengths, unless otherwise known, will be assumed to be that required by USACE criteria at the time of their installation. Pipe condition shall be determined by field assessment.

Gravity lines should be relocated under the crest of the levee if it cannot be located outside of the influence zone. Existing sanitary lines crossing the levee or floodwall will be evaluated by the utility owner (Johnson County Wastewater) to determine structural capacity and condition of the pipes. Any pipes requiring relocation due to levee or floodwall footprint or poor conditions of existing pipe will need to be replaced with a minimum 12-inch RCP. Johnson County Wastewater has requested USACE to design and construct all sanitary sewer relocations associated with this project. USACE requires an agreement between USACE, Sponsor, and utility owner to proceed. Pending approval of the agreement, design will continue after 65% submittal. All existing storm pipes crossing the levee or floodwall need to be replaced with a minimum 24-inch RCP as defined within Part 5, Interior Design. All storm pipes must have a flap gate on the riverside as a passive closure system.

Pressure and communication lines should be relocated over the crest of the levee if it cannot be located outside of the influence zone. Pipes crossing over the levee shall have enough cover for local frost protection, 42 inches minimum. The levee crest will have 10H:1V slopes on both sides of the raised utility to allow for vehicular traffic. Pressure lines need to be designed and constructed to prevent and control seepage and erosion along the pipe. Pressure lines will, at minimum, have shutoff valves on the landside of the levee or floodwall structure located outside of the influence zone.

Before consideration is given to allowing a pressure pipe to remain through or beneath the levee, the pipe owner will provide an engineering study to support their request. The owner, regardless of the type of pipe, must show adequate capability as to the condition of the existing pipe. An agreement will then be formed between the owner and the levee district to the effect that should repairs to a pipe in the levee become necessary, the pipe will be abandoned, grouted, and relocated over the levee.

Pipes that have been abandoned and do not meet criteria will be removed or grouted accordingly. Pipelines that are currently active but are to be abandoned as part of this project will be removed or grouted full in accordance with criteria.

Utility structures should be located outside of the influence zone if feasible. Structures that are placed inside of the influence zone must be evaluated to mitigate any potential breach. Gatewells as an active closure system are not used for this project due to the flashiness of the stream. A deviation memorandum will be drafted at 65% as defined in Part 2. Sanitary pipes should have a manhole located on the landside when feasible. Sanitary manholes located on the riverside of the levee and floodwall structures will have the rim elevation raised to the 25-year storm elevation with a bolted, waterproof cover. Existing manholes will be inspected and lined to prevent infiltration into the sanitary system.

See Appendix C for the detailed Subsurface Utility Engineering table and proposed actions for utilities impacted by construction of this project's levee and floodwall and associated features.

Utilities identified in the table were identified from physical survey and as-built maps provided by utility owners.

10.1.1. Utility Uplift

Will be completed at 65 percent.

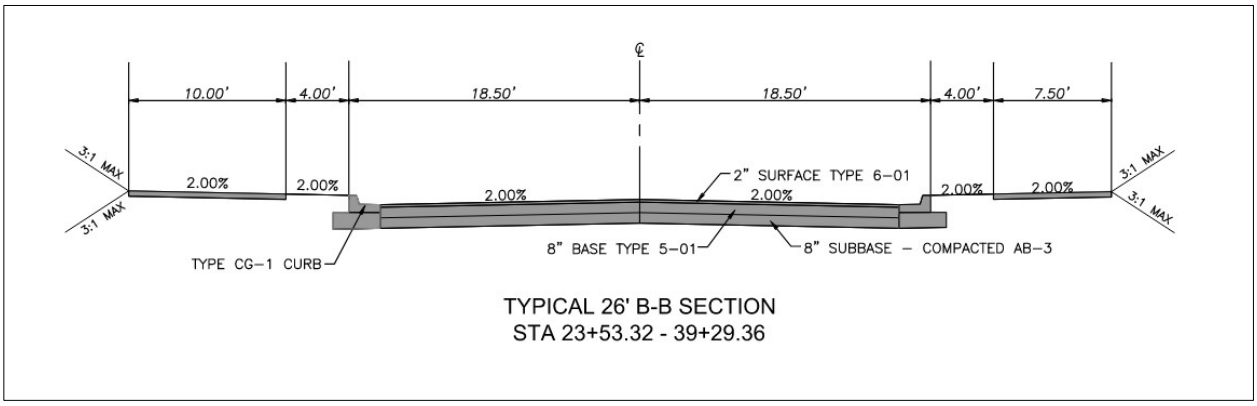
10.2. Bridges

Both vehicle bridges and both pedestrian bridges on this project are impacted by the water surface associated with the 0.01 AEP flood event. Both of the vehicle bridges need to be replaced due to stability concerns. Both pedestrian bridges on this project can remain in place. See Section 9 for further discussion regarding the structural stability of these structures during the design flood event.

In conjunction with the vehicle bridge replacements at Merriam Drive and Johnson Drive, road grading is required to accommodate the new bridge profiles. American Association of State Highway and Transportation Officials (AASHTO) and Kansas City Metropolitan American Public Works Association (APWA) standards were used to grade the road raise designs. HNTB was contracted to complete a conceptual level design for Johnson Drive bridge replacement. See Appendix I for HNTB's bridge report and proposed concept.

Merriam Drive bridge replacement and adjacent road grading was completed in-house. This work includes removing the existing bridge and replacing with a taller and longer KDOT haunch slab bridge, road grading to tie in the bridge raise, along with sidewalk and entrance grading work. Merriam Drive was designed to meet Industrial/Commercial Collector design standards per KCMO APWA 5200. Driveways were designed to meet KCMO APWA standard drawings. Prior to the start of our project, the City of Merriam was working on modifying Merriam Drive to accommodate additional parking and walkability through Merriam's downtown by modifying the road cross section. They have completed designs for their project but decided to pause while we design our FRM project. USACE's bridge and road raise of Merriam Drive will match the City's proposed typical section. Figure 10.1 shows the proposed typical section for Merriam Drive Draft plans provided by the City of Merriam.

Figure 10.1. Merriam Drive Bridge Typical Section.



10.3. Existing Roads

Table 10.1 summarizes impacts to existing roads.

Table 10.1. Roadway Impacts.

Bank	Roadway	Impacts
Left Bank	West 62nd Terrace	Roadway no longer be accessible off of Mastin Street. A floodwall approximately 50ft from the intersection of Mastin St. and West 62nd Terrace will be constructed across West 62nd Terrace.
Left Bank	West 62nd Street	Roadway will have interior ponding adjacent to floodwall during 100 year storm event.
Left Bank	West 61st Street	Roadway will have a floodwall along the curb from Frontage Road to West 62nd Terrace.
Left Bank	Campbell Lane	Roadway will no longer be accessible off of Johnson Drive. A floodwall approximately 20 ft and 175 ft south of Johnson Drive and Campbell Lane intersection will be constructed across Campbell Lane.
Right Bank	West 62nd Street	Cul-de-sac will be partially demolished to accommodate levee toe. Cul-de-sac will be reconstructed approximately 20 ft landward of existing location. Radius to remain the same.
Right Bank	West 61st Street	Roadway west of Merriam Lane will be reconstructed to an access ramp to provide access up and over the levee.
Right Bank	Merriam Drive	The western-most southbound lane south of Johnson Drive intersection will be removed. Three 12.5 ft wide lanes will be present until the existing lane drop approximately XX south of Johnson Drive intersection.
Right Bank	Hocker Drive	Roadway will be partially demolished and reconstructed to an access ramp to provide access to the levee crest.

10.4. Existing Access

The following Section summaries existing and proposed operations and maintenance access as well as existing and proposed pedestrian access.

10.4.1. Operations and Maintenance Access

Table 10.2 summarizes existing and proposed permanent O&M access points.

Table 10.2. Existing and Proposed Operations and maintenance Access.

Bank	Approximate Upper Turkey Creek Station	Existing O&M Access	Proposed O&M Access
Left	63+00	N/A	Propose landside and riverside access off of levee
Right	26+25	Access to creek off of West 61st Street	Propose landside and riverside access off of levee
Right	47+50	N/A	Propose landside and riverside access off of levee
Right	52+75	N/A	Propose landside and riverside access off of levee
Right	57+50	N/A	Propose landside access to detention basin off of levee
Right	61+75	Access to creek immediately south of Merriam Drive Bridge	Access along riverside of levee/floodwall via proposed ramps at approx. UTC Station 52+75

The PDT understands that MDD currently will not cross sanitary lines in the channel with vehicles due to concerns for pipe age and low clearance over the pipes.

10.4.2. Contractor Access

Sheet G-004 of the plan set shows proposed staging areas and contractor access during construction.

10.4.3. Trail Access

The Turkey Creek Streamway Trail is an existing paved trailway within the project limits that will be impacted by the construction of the proposed project. The PDT and Merriam Parks and Recreation are determining trail impacts. Considerations for public access to trails will remain important throughout design. If the trail is between the proposed levee/floodwall and Turkey Creek, the trail could be inundated quickly during flash flood events. During design, access to trails will be assessed and providing adequate alerts and/or evacuation routes during high water events will be evaluated.

Table 10.3 summarizes existing and proposed pedestrian trails.

Table 10.3. Existing and Proposed Pedestrian Trail Access.

Bank	Approximate Upper Turkey Creek Station	Existing Pedestrian Access	Proposed Pedestrian Access
Right	14+80	Access to pedestrian bridge near Merriam Drive and Shawnee Mission Parkway	Propose access around floodwall approximately 5 ft south of floodwall
Left	16+20	Access to private property along West 62nd Street	Propose access around floodwall approximately 5 ft north of floodwall
Left	26+80	Access to trail at Campbell Park	Current design does not impact this existing pedestrian access
Left	39+90	Access to trail at Merriam Lane south of Johnson Drive (bike commuters)	Current design eliminates access to trail south of Johnson Drive. Alternate access along Merriam Lane will be considered in future design.
Right	51+20	Access to pedestrian bridge adjacent to Merriam Marketplace and Werner Park	Propose access up and over proposed levee at existing location

This page was intentionally left blank for duplex printing.

11.0. ENVIRONMENTAL

11.1. Threatened and Endangered Species

During the project design for the Post Authorization Change Report (PACR), it was determined that 4.1 acres would be removed to implement project designs. The PACR concluded that 3.2 average annual habitats units would be required as mitigation based on analysis using the fox squirrel habitat suitability index. However, the project design has been altered, and the riparian and aquatic habitat evaluations will need to be reevaluated. Based on the design changes and a reevaluation of the affected habitat, this updated analysis may conclude that the impacts to riparian habitat would be negligible. If the updated analysis concludes that mitigation is necessary, The USACE determined that on-site mitigation is no longer feasible. Mitigation methods, such as the purchase of mitigation credits or the use of an in-lieu fee program, will continue to be evaluated to identify the most cost-effective mitigation strategy.

Other pertinent environmental considerations include threatened and endangered species due to the timespan of the study and EA and current phase of the project. A search of the U.S. Fish and Wildlife Service (USFWS) Information and Planning Consultation website indicates that activities within this project area have the potential to affect tricolored bat (proposed endangered), monarch butterfly (proposed threatened), and western regal fritillary (proposed threated). Coordination is ongoing with the US Fish and Wildlife Service (USFWS) Kansas Ecological Services Office. The USACE does not anticipate substantial adverse impacts to these species.

11.2. Cultural Resources

Section 106 of the National Historic Preservation Act requires federal agencies to take into account their actions on historic properties, that is, those cultural resources that are listed on or eligible for listing on the National Register of Historic Places (NRHP). To that end, archeologists from the USACE have completed several tasks to date, including a reconnaissance survey of the project area in 2012 and a historic architecture survey in 2025. USACE consulted with the Kansas State Historic Preservation Office (SHPO) regarding the archeological potential for the project area and the Kansas SHPO concurred with USACE's determination that the project should have no effect on historic properties below the surface.

Several standing structures have been selected for buy-out and demolition for the project. In a letter dated February 2023, the SHPO agreed that these structures (regardless of age or condition) must be recorded and evaluated for their eligibility for listing on the NRHP. USACE archeologists recorded all of the structures within the footprint and consulted with SHPO on their eligibility. USACE determined that at least three of the structures were eligible for the NRHP and SHPO concurred.

A Programmatic Agreement (PA) was developed to identify, evaluate, and resolve adverse effects to historic properties, including the eligible buildings, during a future phase of the project. Consulting parties include the Kansas SHPO, City of Merriam, Shawnee Tribe, Osage Nation, Pawnee Nation, Kaw Nation and Omaha Tribe of Nebraska.

11.3. Hazardous, Toxic, and Radioactive Waste

A records search for potential contaminated sites along the reach of Turkey Creek addressed by this DDR was performed in 2009, updated in 2015, and updated again in 2023. Based on the findings from the records search, there are no known superfund sites that will impact the proposed work. In addition, no solid waste facilities, such as former landfills, were identified at

locations that would impact the project. There were several spills reported near Turkey Creek along the reach addressed by this DDR, but they were quickly remediated and should not have any significant impact to the project. There are six properties with current or former USTs, with the status of the tanks unknown on two of those properties, 5560 Merriam Drive and 5745 Merriam Drive, which are no longer in use. There is no known existing contamination associated with any of the current or former tank locations, although some contamination was encountered and remediated when tanks were closed and removed.

A GPR study performed on properties along the channel found subsurface anomalies on 5568 Merriam Drive, 5726 Merriam Drive, 5639 Merriam Drive (DS Bus Lines), 5643 Merriam Drive, 9400 West 61st Street, 9420 West 61st Street, and 80 feet west of the intersection of Merriam Lane and West 61st Street. The nature of the subsurface anomalies is unknown but two of the properties, 5556 Merriam Drive and 5639 Merriam Drive, had historical USTs. Records show the USTs on 5639 Merriam Drive were removed and there was no contamination (but currently have two 10,000-gallon USTs in use) and the status of the UST on 5568 Merriam Drive was unknown but believed to no longer be in use. Appendix F contains additional information on the GPR survey.

Two areas of concern were discovered during a February 2023 soils investigation. Buried railroad ties, stained soil, and debris were discovered while advancing a boring on 5726 Merriam Drive. This may present foundation issues for the proposed levee along this reach as well as issues with construction of a retention basin proposed on this property. The other issue discovered during the February 2023 soil investigation was petroleum contamination located on city property just north of 5920 Merriam Drive at a depth of 10 to 11 feet below the ground surface. Sample results indicated total petroleum hydrocarbon (TPH) levels above residential values for mid-range hydrocarbons but below non-residential levels. Volatile organic compound (VOC) analysis results were all non-detect, which suggests the source of contamination is very old and the underlying constituents driving the health-based TPH risk levels have degraded over time.

Overall, the risk of encountering significant environmental/hazardous, toxic, and radioactive waste impacts during construction appear relatively low based on Federal and State environmental records. However, there remains uncertainty about activities that occurred prior to Federal/State regulations being enacted and records kept. An example of this is the debris encountered at 5726 Merriam Drive and the petroleum contamination just north of 5920 Merriam Drive, both discovered during subsurface investigations performed in February 2023. Neither of these sites were expected to have contamination issues based on environmental records. It is not possible nor cost effective to identify all potential environmental subsurface issues along a greater than one-mile portion of the channel addressed in this DDR. The density of borings and other investigative techniques would be both schedule and cost prohibitive due to the potentially isolated nature of contamination. Therefore, it is recommended that the contractor be required to develop contingency plans to address unexpected environmental conditions and contingency funding be set aside so unforeseen conditions can be addressed without significant project delays.

As for the two recently discovered sites with environmental concerns, 5726 Merriam Drive and just north of 5920 Merriam Drive, it is recommended additional investigations be performed to characterize the nature and extent of the environmental issues more fully on these properties. This can be performed either by USACE during design or by the construction contractor. For the debris at 5726 Merriam Drive, it is likely all debris below the proposed features will need to be removed and disposed of at a permitted facility. For the petroleum contamination encountered just north of 5920 Merriam Drive, based on the TPH levels, it does not appear any remedial activities would need to occur. However, it is good practice to segregate any contaminated soil

from clean soil excavated and dispose of it at a permitted landfill rather than reusing the soil on site or at other project locations. In this case it would likely be classified as a special waste that could be disposed of in a Resource Conservation and Recovery Act (RCRA) Subtitle D landfill, which is the type of landfill that accepts typical household waste.

There were no sites of hazardous, toxic, and radioactive waste concerns identified south of 61st Street within the limits of proposed DDR activities.

Refer to Appendix F for more detailed information on specific sites identified and figures showing the location of the properties of concern relative to project features.

This page was intentionally left blank for duplex printing.

12.0. REAL ESTATE

12.1. General

The project's purpose dictates which real estate must be acquired by the Non-Federal Sponsor (NFS). Along the levee footprint, the NFS owns or has easements for some of the properties required for the project. However, most land in the project area requires the NFS to obtain additional easements or fee acquisitions. Also, MDD operates on lands for which it does not hold easements to, which will also require the NFS to acquire these lands as part of the project.

12.2. Survey

The real estate limits and title survey, completed by Stockwell Engineers Inc. with AE Assistance, were finalized on 14 March 2024. The survey was conducted to help identify those boundaries for the required land needed for the project.

12.3. Site Specific Information

The City of Merriam, Kansas, owns 3.41 acres in fee along the project which will be made available for the project. There are 129 parcels identified within the project area.

12.4. Utility Relocations

The project design requires the relocation of numerous utilities. The NFS is responsible for coordinating with the utility owners and facilitating the relocation of each. Impacted utilities will be included in the 65 percent DDR.

12.5. Site Access

Temporary access for sites that are not part of public roadways will be acquired by the sponsor and will be shown on the real estate exhibits.

This page was intentionally left blank for duplex printing.

13.0. FUTURE CONSIDERATIONS

This project is pausing at 50% design. Below is a summary of future considerations for the PDT when this project continues.

13.1. PM Considerations

- Project Deliverables: 50% design, PACR, and AE (HNTB) submitted deliverables.
    - 50% design (plans and DDR) can be found at – "K:\MissionProjects\civ\turkeycr\505229 Upper Turkey Creek CG\6.0 Engineering-Design\6.5 Product for Release\6.5.2 65% deliverables"
    - PACR documents (Executive Summary, Body of Report, and Appendices) can be found at – "K:\MissionProjects\civ\turkeycr\505229 Upper Turkey Creek CG\14.0 PACR\Report". The Decision Document Checklist and Study Issue Checklist are found at the same K: Drive location seen in this bullet. All of the PACR documents will need to be updated when the project comes off the shelf and re-starts.
    - HNTB submitted deliverables can be found at – "K:\MissionProjects\civ\turkeycr\505229 Upper Turkey Creek CG\9.0 Contracting\9.4 AETaskOrder\9.4.5 Deliverables"
- Decision Log location – "K:\MissionProjects\civ\turkeycr\505229 Upper Turkey Creek CG\1.0 Project Administration"
- All PCRs can be found at – "K:\MissionProjects\civ\turkeycr\505229 Upper Turkey Creek CG\1.0 Project Administration\1.1 Project Management Plan\11.0 Change Management".
- While the team was revising the PACR from NWD/ATR reviews and working on the 65% design, USACE met with the City of Merriam. In these discussions with the Sponsor, it was relayed that the City Council will need to review the levee/floodwall design and decide if the City would like to move forward with the levee/floodwall project or if they would like to proceed in a different direction. With the need for the Sponsor to be in full support of the project during the PACR process and to not spend the Sponsor's or USACE's funds unnecessarily, USACE and the City of Merriam decided that we would pause the PACR and shelve the design at 50%. If the City does decide to move forward with the levee/floodwall project, USACE will pick up the design at 50% and resume the PACR for WRDA28.
- The 50% design includes the plans and DDR (no specs). Levee/Floodwall is at 65% design; bridges were closer to 35% design, which is why USACE is calling this the 50% design.
- The 50% design plans to obtain an updated Certified Cost Estimate from the MCX (Walla Walla).
- The PACR was stopped after the Draft Report was sent through ATR/NWD and HQ Policy Review. The Final Report was to go back through ATR and Policy Review, as the Environmental Section and Induced Impacts needed revisions, and the Certified Cost Estimate needed to be revised with 2026 CWICCS numbers. When and if this project is picked back up, the PM should verify with NWD to see if the PACR Final Report needs to go back through ATR. Driving need for PACR was the cost (almost doubling the authorized cost).

- One of the comments from NWD & HQ Policy Review was completion of a Cultural Resources Programmatic Agreement (PA). We had started the PA before it was determined that the PACR would be paused. The City of Merriam would like to pause the PA and it will be picked back up if the project resumes. All information regarding this is saved at – "K:\projects\pogis\admin\Archaeology\CR Project Folder\Kansas River\4. Reports\2026-NWK-002-Upper-Turkey-Creek\7-PA".
- Brief Timeline
    - Authorized under WRDA16 – December 2015
    - Funding Received/Design Initiation – June 2022
    - 35% design complete – Winter 2025
    - PACR started – Fall 2024
    - PACR stopped – Winter 2026
    - 50% design complete – Spring 2026
    - Project shelved – Spring 2026
- Regarding Induced Impacts – please reference the PCR at - "K:\MissionProjects\civ\turkeycr\505229 Upper Turkey Creek CG\1.0 Project Administration\1.1 Project Management Plan\11.0 Change Management\2026\PCR #2". As of February 2026, USACE has not yet determined how to account for Induced Impacts. For Upper Turkey Creek, flowage easements required for upstream and downstream of the project could range from $4M to $107M.
- Budget Summary – will update when project is closer to being shelved.
- We know of petroleum being discharged in some places along the project ROW. Superfund contaminants would be a non-project cost and the responsibility of the Sponsor. Petroleum is normally a project cost to remove/remediate. Verify when and if this project is taken off the shelf for further design.

13.2. Design Considerations

- H&H Levee Profile
    - It is recommended that a full update to the levee profile be computed with the 85% assurance target in HEC-FDA utilizing the most up to date hydraulic results from design
    - The left bank flood protection alignment was refined prior to the 50% submittal. A shortened analysis was performed in HEC-FDA at only the locations where the water surface profile increased compared to the post-35% design iteration. Due to time constraints, these locations of needed increase to levee/floodwall heights were not implemented in the plan. Detailed information can be found in the Section 4.6.7.
    - A full re-run of HEC-FDA is recommended because the left bank refinements dropped the water surface profile on average relative to the post-35% profile. But due to schedule, locations where the levee heights could be reduced were kept the same to minimize rework for Civil Design.

- Consideration should be given to the possibility of a designated overtopping location if this project resumes in the future. The City of Merriam may have a master redevelopment plan by that point in time that could present an ideal location to design for initial overtopping.

- H&H Channel Scour/Erosion documentation
  - It is recommended that an analysis on the scour potential for the channel is completed in a future submittal. The proposed design is expected to constrain more flow to the channel compared to FWOP conditions. Though it is unlikely for channel scour to be a large concern given the almost entirely bedrock channel bottom, analysis and documentation stating as much is needed to confirm.
  - Channel scour and erosion at the pedestrian bridges should also be future investigated. Based on the analysis that has been conducted, there isn't a concern for scour, but if the water surface profiles are updated to meet new standards, this should be re-evaluated to confirm that there is no additional concern for scour at the pedestrian bridges.

- FEMA Water Surface Comparison
  - It is recommended that once the levee design is near finalization to conduct a comparison to FEMA water surface elevations, profiles, and inundation maps. A rise in water surface is expected with the current design, but a comparison should be documented for future reference.
  - FEMA floodplain mapping for Turkey Creek may be updated between the date of this 50% design submittal and when the project resumes. The fully 2D FEMA map was in draft stage at this point in time and the subsequent mapping from that recent study may supersede the effective products as of Spring 2026..

- T Wall and I Wall Design
  - Preliminary calculations and considerations for the connections of the I walls to the top of the sheet pile section were made such that the wall thickness for the I walls tapers to match the thickness of the T Wall sections. Reference 9.0 STRUCTURES for additional information on the I Wall and T Wall design. Section sizes may need to be further updated to limit deflections and meet serviceability requirements.
  - Additional design considerations should take into account the land usage behind the floodwall. In particular, areas along the right bank, where heavy industrial or automotive types of land use are located directly behind the floodwalls, additional surcharge loadings and additional dead loads from stored materials and heavy wheel traffic should be analyzed to confirm that there are not additional shear demands for the toe of the floodwall foundation that would require additional design considerations.
  - Discussions with Construction and previous experience with T Wall construction on projects like Swope informed that the contractor constructing the T Wall's foundation may want to substitute in a significantly larger section for the T Wall's foundation key than the design drawings show. A preliminary set of CT Wall runs were made for a 10 ft wall section and found that the wall had an insufficient factor of safety for stability. Future designers should consider creating alternate profiles for the T Wall foundations before the project goes to construction so that

initial conversations with the contractor can be had as to what the potential new geometry for the foundation key could be.

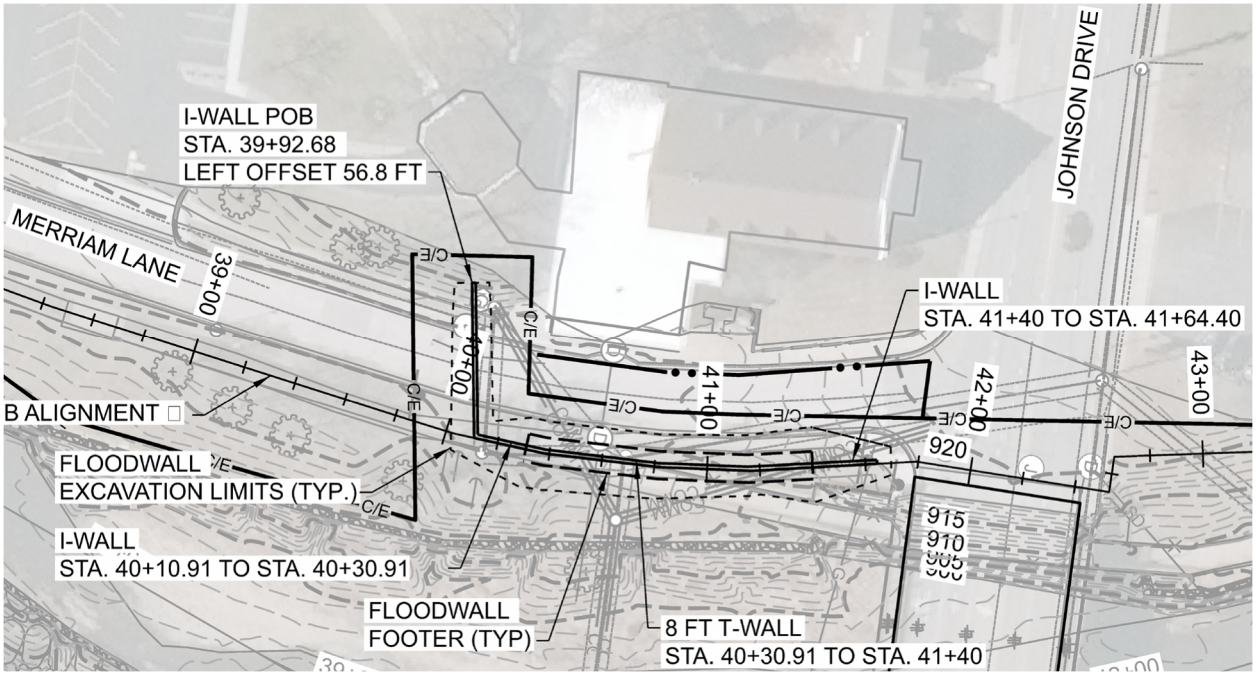
- Outfall Storm Structures, gatewell structures
    - Future considerations for the stability and serviceability of the outfall structures for the storm sewer system should be made. Outfall structures were preliminarily sized to match roughly the land profile of the embankment approximately where the structure is to be located. The limestone wall was not considered in the initial layout of the outfall structure. Future designers for the structures should consider the rotational stability if the outfall structure is shortened to match to the land profile created by the limestone block wall. This new layout would make the outfall structure tall with a narrow base and considerations should be made to move the toe of the structure further behind the wall of the outfall. Structural plans should be updated to include the revised geometry and could possibly include drawings showing the block wall interaction with the new structure and where grouting around the blocks could be used to prevent differential movement between the limestone and the new outfall structures.
    - Outfall structures as they are currently detailed do not include any hoisting mechanism for opening the flap gates attached to the front faces. Past projects have employed the use of a steel tube attached to the top face of the wing walls of the structures such that a chain hoist or come-along winch could be used to safety open the flap gates for inspection.
    - Additional research should be done to find suppliers of flapgates and considerations should be made for the types of material based on producer lead times and long term maintenance issues. Cast Iron gates could be used for the smaller or round pipe openings. Considerations should be made for the gates that will be required at the larger openings such as the detention basin outfall and the Quaker Creek Box Extension.
    - The Quaker Creek Box Extension and the juxtaposed T Wall foundation sections should be analyzed for potential differential settlement issues. Considerations should be made to attach the T Wall sections and their foundations to the side walls and wing walls of the box extension. This joint could potentially have a post-installed waterstop and anchors similar in nature to the post-installed waterstop used at the junction between the existing structure and the new extension of the structure. This would allow for some differential movement between the side walls of the box and the foundations of the T Walls. Another potential consideration would be a smooth dowel connection to the side walls and foundation that would prevent differential settlement between the structure and the T Wall foundation, and would allow for expansion and contraction movements between the foundations and the box structure.
- Bridge refinements
    - Floodwall tie-ins to the bridge will need more refinement and coordination to make sure the bridge and the floodwall line up and include proper detailing. Currently the bridges are planned to be replaced before the construction of the floodwall sections. This will require that the floodwalls tie in to the abutments of the bridges either side of the abutment. Considerations should be made so that the contract drawings have flexibility in the location of these abutments, and allow for ease of construction by the contractor.

- Detours have been provided by the City of Merriam from the last time Johnson Drive was replaced. These detours will need refinement as the design progresses.
- Consider reducing the length of Merriam Drive bridge from 180ft long to 170ft long to reduce the impacts to the bus barn property. H&H would have to re-evaluate the 1D model at the bridge.
- Grading adjacent to and under Merriam Drive bridge will need to be coordinated and shown on the plans. An existing access ramp immediately upstream of Merriam Drive bridge on the right bank will be removed and the area will be regraded so that the area landside of the proposed floodwall grades to drain toward the storm inlet along the roadway.
- The storm outfall immediately downstream of Johnson Drive bridge will need to be coordinated with the bridge abutment. Scour protection measures will also need to be coordinated.

- I-wall location refinements – There is a potential to utilize I-walls in more locations if we add fill around the floodwall an additional one to three feet above the existing ground. Consider taking one last look at potential I-wall locations.
- Settlement of subgrade soils under pipes should be evaluated at utility pipe crossings.
- Alignment refinements – after I-wall location refinements have been identified, consider reevaluating floodwall alignments, especially where riprap riverside of I-wall is planned. A smaller riverside riprap footprint is needed for I-walls, leading to potentially shifting small ranges of floodwall alignments riverside several feet. H&H would need to verify any riverside shift does not negatively impact the minimum level of protection needed.
- Levee Betterments – The Sponsor will decide whether or not to include a betterment to all or some ranges of levee within the project area. Betterment options include (1) widening the levee by 4 feet, (2) adding an asphalt trail atop the levee, (3) adding several levee “bump-outs” along the landside of the levee to accommodate benches, or a combination of these betterment options.
- Refinements adjacent to 9401 Johnson Drive (Merriam Christian Church)
  - Consider modifying the alignment of the proposed floodwall adjacent to 9401 Johnson Drive. Current configuration cuts off an existing access point to Turkey Creek Trail immediately sound of Johnson Drive Bridge along the left bank. Potentially shifting the alignment north could allow the existing access point to remain in-place or be modified to continue to allow access to the trail at this location.
- Interior drainage along Johnson Dr west of bridge – The current left bank alignment at Merriam Christian Church shown below in Figure 13.1 allows for drainage flowing east from Johnson Dr (top right portion of the figure) to flow south along Merriam Lane behind the floodwall. The interior drainage ponds behind the wall and inundates the church basement. A new curb inlet was examined to be placed along the south edge of Johnson Dr before the intersection with Merriam Lane to intersect this drainage. Rational Method analysis of the watershed and FHWA HEC-22 inlet design determined a curb inlet with 5’ wide opening was only 16% efficient at capturing drainage along Johnson Dr. Due to this, the floodwall alignment should be shifted to tie into high ground on the Merriam Christian Church property instead of Johnson Dr bridge and close the entrance to Merriam Lane. This would allow the drainage along Johnson Dr to flow directly into the

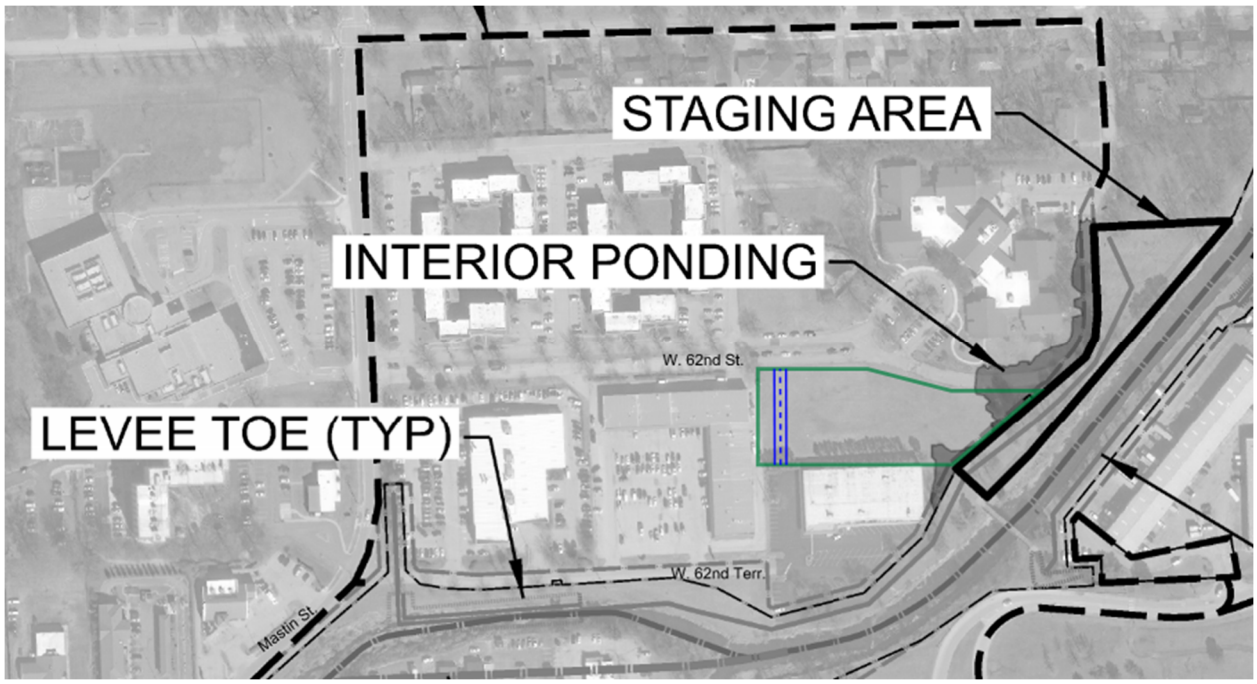
channel. This change would cut off access to the church basement and dumpster area from Merriam Lane and would require the property to move this access.

Figure 13.1. Current left bank alignment of floodwall at Merriam Christian Church.



- Sanitary Sewer Design – Johnson County Wastewater has expressed interest in USACE designing and constructing sanitary sewer relocations as a part of this construction contract. This requires an agreement with USACE, Sponsor, and Johnson County Wastewater to proceed. In order to minimize impacts to the project, only sanitary sewer directly impacted by the alignment of the project was deemed to be relocated. All other sanitary sewer work will be handled on a case-by-case basis on the conditions of the infrastructure. Johnson County Wastewater has shared data within the Johnson County AIMS online system that contains reports and videos on all of their manholes and sanitary lines within the project area. Design of the sanitary system must conform to UFC guidelines and Johnson County Wastewater typical specifications. Construction of the sanitary relocations may include phasing and pumping plans as some of the relocations will be in the same location as existing pipes.
- Staging Areas – Consider expanding the staging area on the left bank off of W. 62nd St, to the area immediately north of 9800 W. 62nd Terrace (Skate City). With the addition of the tieback levee/floodwall crossing W. 62nd Terrace east of the Mastin St. and W. 62nd St. intersection, the business at 9800 W. 62nd Terr. will need new access. A new access entrance off of W. 62nd St. is a logic location. New access will be discussed with the property owner during Real Estate Acquisition.

Figure 13.2: Left Bank Potential Staging Area Expansion.



13.3. Communication

- Getting the constructed project FEMA accredited is the Sponsor's top priority, especially in the downtown reach. If this project continues, suggest setting up meetings with FEMA to get a better level of assurance that this is possible with the proposed profile at 1% AEP with 85% assurance.

13.4. Environmental Considerations

- The impacts were modeled, then the design was modified at 50%. Since we were awaiting the Sponsor's concurrence on the PACR and the overall project, and USACEs decisions regarding Induced Impacts and the overall project, we did not remodel the impacts to riparian and aquatic habitat. These items will need to be reevaluated. The updated analysis may conclude that the impacts to the riparian habitat would be negligible.

14.0. COST ESTIMATE

14.1. General

The Upper Turkey Creek Flood Risk Management (FRM) project is a new project located in the City of Merriam, in Johnson County, Kansas. Turkey Creek is a right bank tributary of the Lower Kansas River located in Johnson and Wyandotte counties, Kansas between approximate river miles (RMs) 2.7 to 3.7. This project includes placing new levees or floodwalls, utility relocations, and replacing Merriam and Johnson Drive bridges to increase the current line of protection. The 65 percent current working estimate (CWE), including Cost and Schedule Risk Analysis (CSRA), will be developed and will be certified by the Mandatory Center of Expertise (MCX) and will be complete around May 2026. The DDR will be updated after the 65 percent CWE is completed. The current working estimate is not considered Controlled Unclassified Information.

14.2. Contract Acquisition

The acquisition method is assumed to be full and open invitation for bid (IFB).

14.3. Estimated Project Duration

Construction Schedule will be updated after 65 percent CWE.

14.4. Basis of Estimate

The basis of the estimate is the 65 percent drawings. 65 percent specs will not be provided. The estimate is based on three contracts and the assumed midpoints of construction for each were provided by the project manager.

14.5. Estimate Preparation

This cost estimate was prepared using the Micro Computer Aided Cost Engineering System (MCACES) Second Generation (MII), version 4.4.3. Subsections 15.5.1 through 15.5.4 detail the supporting databases used in the preparation of the cost estimate.

14.5.1. Cost Book

CB24EN (2024 MII English Cost Book); each unit cost was analyzed and adjusted to reflect current costs.

14.5.2. Labor Rates

This estimate uses a prevailing wage labor rates for Jackson County, Missouri. The latest Davis Bacon were used for preparing the estimate.

14.5.3. Equipment Rates

This estimate is based on the latest available/supported MCACES MII equipment rate database (EP22R05), which has been updated for the estimate to more accurately represent current prices.

14.5.4. Contractors/Subcontractors

The estimate assumes the majority of the work will be performed by the prime contractor, but some subcontracting will be needed by the prime to execute the project.

A surety bond rate was assumed for the prime contractor. The bond rate is calculated by the MCACES MII software.

The following markups were applied to the prime contractor's work:

- Job Office Overhead
- Home Office Overhead
- Profit
- Bond
- Contingency.

Currently a contingency of XX percent will be applied until further design detail is provided. Other specific percentages are retained in MII.

The following markups were applied to any subcontracting work:

- General Overhead
- Profit.

An equipment adjustment factor has been applied to the 2022 equipment prices to update the equipment to current pricing. An equipment adjustment factor has been applied to all equipment items. The adjustment factor has been derived by assuming and escalation factor of 5.0 percent per year.

A material adjustment factor of has been applied to the 2024 Cost Book Material prices to update the materials to current pricing. The adjustment factor has been derived from the Engineering News Record index for construction material.

A sub bid adjustment factor has been applied to the 2024 Cost Book Sub Bid prices to update the sub bids to current pricing. The adjustment factor has been derived from the Engineering News Record index for construction cost.

14.6. Project Owner Markups

The owner also has markups on the project level that are applied after contractor markups. These markups include:

- Escalation
- Supervisory and administration
- Construction contingency is included in design contingency.

14.7. Cost Drivers and Risks

Updating the CSRA after each design submittal will help better define cost and schedule risks and provide confidence levels in being able to complete the project at various funding amounts. High level risks include:

- Will be updated with 65 percent CSRA risks

14.8. Market Conditions and Competition

A large factor in the total project cost will be the number of bids received as open competition has a significant impact on receiving a fair and reasonable price. Historical data shows a small labor pool and the lack of labor could affect cost and schedule.

14.9. Scope Uncertainty

There are many unknowns in the current scope that could impact the total project cost. The estimate will change throughout design as the scope becomes better defined. Below are a few of the unknowns.

- Fill material sourcing is not final.
- Unknown condition of limestone retaining wall.
- Possible new bridge.
- Long term city plans.

This page was intentionally left blank for duplex printing.

15.0 PROJECT FEATURE CHANGES DUE TO ENGINEERING DURING CONSTRUCTION

The DDR should be updated at the completion of construction to document engineering changes that resulted from construction activities. This chapter should be organized in a “by feature” discussion of changes to previously described designs. For example, if anticipated inspection trenches were extended to provide proper cut off, unexpected utilities, unexpected foundation conditions, etc.

This page was intentionally left blank for duplex printing.

APPENDIX A.2 – CFS BORROW AREA BORING LOGS

2025 CFS Subsurface Investigation

In 2025, Cook, Flatt & Strobel Engineers (CFS) conducted a subsurface investigation at the planned Merriam Grand Station North project site, a portion of which the City of Merriam has identified as a potential borrow source for Upper Turkey Creek levee construction. A total of five borings (Borings B1 through B5) were conducted in the area identified as a potential borrow source. The potential borrow site is in the north central portion of the lot bounded by West 62nd Street to the north, Slater Street to the east, Shawnee Mission Parkway to the south, and Ikea Way to the west in Merriam, Kansas.

The planned construction within the potential borrow area consists of a multistory apartment building with a below grade parking garage. Per the geotechnical report by CFS dated 12 February 2025, the finished floor elevation of the lowest parking level is expected to be at 1008 feet above sea level. Based on Google Earth topography, the site slopes down from north to south from approximate elevation 1015 feet to 1005 feet, with about half the site below 1008 feet. The potential borrow soils consist of excess material from this excavation.

The site is planned to be excavated in December 2025 with any excess material stockpiled. The City of Merriam will inform USACE of how much material is stockpiled for use as borrow.

Split spoon samples and rock cores were taken at the boring locations. The boring logs show an average of three feet of lean clay fill below the asphalt parking surface and aggregate base. The fill is underlain by natural lean clay, with weathered limestone encountered at 4 to 11 feet below grade. In two of the five borings, the fill material was described as with gravel. Atterberg limits were tested on one sample, with a Liquid Limit of 38 and Plasticity Index of 24.

Based on the visual classifications given in the boring logs and on the limited laboratory testing, the material is assumed to be suitable for use as impervious fill. It is unclear if there will be a significant amount of borrow available from this site. If the project is delayed for a significant period, the City of Merriam may use this borrow elsewhere.

Boring Location Plan and pertinent Boring Logs are included in this Appendix.

Regarding:

Geotechnical laboratory testing for the Upper Turkey Creek Project including USCS Classification, Water Content, Consolidation, Unconfined Compression, UU Triaxial, CU Triaxial and Uniaxial Compressive Strength Core testing.

Comments:

As previously communicated in emails, the following issues were found with the samples:

- Boring No. ADU-197; Sample W-1; 5 to 7 feet: Due to the substantial presence of rock in the sample, we were unable to conduct the CU Triaxial testing.
- Boring No. ADU-200; Sample W-1; 5 to 7 feet: Due to the substantial presence of rock in the sample, we were unable to conduct the CU Triaxial testing.
- Boring No. ADU-204; Sample W-1 2 to 4 feet: The limited quantity of sample recovery allowed us to obtain only two samples for CU Triaxial testing.

We have not been asked to interpret the data or make design and/or construction recommendations based on the data and cannot assume responsibility or liability for interpretation of this data by others.

Troy B. Bandy, PE

☐ Field Data ☒ Laboratory Data ☐ Report

Regarding:

Geotechnical laboratory testing for the Upper Turkey Creek Project including USCS Classification, Water Content, Particle Size Distribution, and Consolidated Undrained shear strengths.

Comments:

The following issues were found with the samples:

- Samples from ADU-206 and ADU-207 were not able to be tested for Consolidated Undrained shear strengths or accurate water content due to the samples being dried out and breaking when trimmed. The USCS Classification was not performed on these samples.

We have not been asked to interpret the data or make design and/or construction recommendations based on the data and cannot assume responsibility or liability for interpretation of this data by others.

Mohamad Ibrawish, PE

Submit more samples for testing after received results from the first round, most too dry/disturbed for testing

B.1 Underseepage
B.2 Global Slope Stability
B.3 I-Wall Design
B.4 Floodwall Bearing Capacity
B.5 Levee and Floodwall Settlement
B.6 Riprap and Bedding Design
B.7 Floodwall Toe Drain Design

This page was intentionally left blank for duplex printing.

APPENDIX B.1 – UNDERSEEPAGE

Underseepage Assumptions

Boring Profile

Underseepage Analysis

Regional Underseepage Criteria

District Underseepage Criteria

Underseepage Assumptions

- Divided the levee alignment into 5 reaches. As the subsurface profile and distance from the levee system to the creek were relatively consistent throughout the alignment, the divisions were made primarily based on top of bedrock elevation.

- Due to existing ground surface elevation differences (and some variation in top of bedrock elevations) between the left and right banks, subdivided the reaches as Reach 1 LB, Reach 1 RB, etc.

- Landside and riverside ground elevations for underseepage are based primarily on the levee centerline existing elevation. The site is generally uphill landward of the levee centerline.

- Levee stationing is given according to the August 2025 alignment, which will likely change, and according to the UTC creek centerline stationing, which will remain constant through the project. If there is a discrepancy, the UTC creek stationing should be referenced.

- Seepage lengths are based on the alignment shown in the August 2025 kmz file.

- Within each reach on each bank, selected the tallest levee and floodwall for underseepage analysis. Not all reaches had all feature types.

- The soil profile shows upper fill soils occasionally listed as gravelly or with debris. It is assumed that the overall soil matrix is clayey and there is no continuous pervious zone. An inspection trench will be excavated during construction. If evidence of a continuous pervious zone is found, an impervious or grouted cutoff may be required.

- The soil profile shows an inconsistent gravelly clay/clayey gravel zone near top of bedrock. It is not found at all in many borings and is up to 8.8 feet thick in other borings, making it difficult to develop a design soil profile for each reach. In general, the pervious zone due to sand or gravel was averaged to one or two feet thick.

- As the general soil profile is clayey fill or clayey natural soil down to shallow bedrock with no consistent foundation sand layer, the underseepage analysis is different from the Argentine Levee Raise, Manhattan Levee Raise, Topeka projects, and other recent analyses. It is not known if the lower gravelly clay zone is pervious enough to transmit a significant amount of seepage or if the more likely seepage source would be the bedrock.

- It was decided to perform the underseepage analysis with a larger pervious zone in the gravel or bedrock (worst case).

- As the permeability of bedrock is difficult to predict, it was assumed there would be no limiting factor as to the thickness of the pervious zone in blanket theory calculations. The top of bedrock elevation (bottom of pervious blanket in the blanket theory spreadsheet calculations) was lowered in even increments of 10 feet (example from EL 915 to EL 910 to EL 900, etc.) until the change in vertical underseepage factor of safety for a 10-foot difference was less than 0.05.

- Underseepage pressures in slope stability analyses were calibrated to match the head at toe elevation in the blanket theory spreadsheet.

- All underseepage and stability runs are based on steady state conditions with top of levee loading from Upper Turkey Creek. As this is a flashy creek, long term steady state conditions are not expected to occur. This assumption brackets the worst-case scenario.

- The impervious blanket is assumed to be infinite on the landside. There is no evidence of a seepage block near the levee.

- Using permeability of 0.003 ft/sec for pervious stratum as typically used for Missouri and Kansas River levees with similar soils (see DM-1 for L-476, p. I-15. See Argentine Levee Raise and South Topeka Floodwall Modification.) This value is also within published typical range of values for coarse sand.

- Used initial permeability for impervious fill and impervious blanket in GeoStudio based on permeability ratio of 400 (7.5 e-06 ft/sec) then adjusted until head at levee toe matched blanket theory spreadsheet so results calibrated to match the spreadsheet.

Underseepage Blanket Theory Spreadsheet Parameters

Parameter	Assumption
Top of Levee Elevation (ft)	Assumed water loading to top of levee/floodwall per the profile from civil dated 13 August 2025
Riverside Ground Elevation (ft)	Used existing ground elevation at levee centerline for both riverside and landside elevations. The ground surface generally slopes uphill landward of the levee, so using ground elevation at centerline results in the largest head difference.
Landside Ground Elevation (ft)	
Landside Tailwater Elevation (ft)	Using landside ground elevation
River Blanket Bottom Elevation (ft)	Not differentiating from riverside to landside w limited info. Assuming no continuous pervious zones in upper fill materials. Taking as average bottom of CL or ML layer.
Land Blanket Bottom Elevation (ft)	
Top of Bedrock Elevation (ft)	Initially taken as SPT or auger refusal or beginning of rock core elevation for best case. Adjusted to elevation where factor of safety no longer changes significantly (as described above) for worst case.
Permeability Ratio (K_f/K_b)	Using 400, corresponding to Silty Lean Clay in KC Underseepage Guidance
Riverside Seepage Length (ft), L_1	Distance from riverside toe of levee or floodwall to the bank of Upper Turkey Creek. There is no significant exposed continuous pervious stratum for ending L1 before the bank of the creek.
Levee Seepage Length (ft), L_2	Width of levee or floodwall. Using 10-foot crest and 1V:3H slopes for levee from top of levee to existing grade. Using footing width for floodwalls.

MEMORANDUM FOR

CENWK-ED (David Mathews)
CENWO-ED (John Bertino)
CENWP-ED (Lance Helwig)
CENWS-ED (JoAnn Walls)
CENWW-ED (Brian Miller)

SUBJECT: HQUSACE Concurrence of the Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED) Underseepage Criteria

1. Reference memorandum, CECW-CE, dated 08 May 2015, subject same as above, (encl).

2. I am pleased to transmit the referenced memorandum that documents HQUSACE concurrence with the MRLS R-471-460 & L-455 PED Underseepage Criteria.

3. This criteria should be considered "Regional Criteria" to be applied to design of underseepage berms for other projects in NWD Districts until revisions to EM 1110-2-1913 (including Appendix C – Design of Underseepage Berms) are completed. The "Regional Criteria" intent has been worked through the regional geotechnical engineering community of practice and input from that group incorporated into the criteria document.

4. My Points of Contact for this memorandum are Dr. Yong Rhee, Senior Geotechnical Engineer, (503) 808-3831 or Yong.H.Rhee@usace.army.mil, or Mr. Scott Vollink, Levee Safety Program Manager and Acting Levee Safety Officer, (816) 389-3600, or Scott.D.Vollink@usace.army.mil.

MEMORANDUM FOR Commander, Northwestern Division, U.S. Army Corps of Engineers, CENWD-DE, 1125 NW Couch St., Portland, OR 97209

SUBJECT: HQUSACE Concurrence of the Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED) Underseepage Criteria

1. References:

a. Memorandum, CENWD-RBT, dated 22 April 2015, subject: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED) Underseepage Criteria, (encl).

b. Memorandum, CENWK-ED-GD, 08 April 2015, subject: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED); NWK 2013 Underseepage Criteria; Revised per USACE-HQ Comments.

2. This memorandum documents HQUSACE concurrence of the proposed underseepage criteria for use on the Missouri River Levee System (MRLS) R 471-460 & L-455 levee projects.

3. The point of contact for this action is Mr. Steven Kopecky, Deputy Chief, Northwestern Division-Regional Integration Team, who can be reached at (202) 761-4527.

MEMORANDUM FOR Deputy Commander, Northwestern Division, ATTN; CENWD-RBT (Douglas Putman), 1125 NW Couch, Suite 500, Portland, Oregon 97209

SUBJECT: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED) Revised Underseepage Criteria; Document Transmittal for Major Subordinate Commander Approval

1. Purpose. This memorandum transmits for approval the third version, second revision, of MRLS R 471-460 & L-455 PED Underseepage Criteria and official responses to comments provided by USACE-HQ. Three final comments were received by CENWK via an email from CENWD dated 30 October 2014. The comments regarded an incorrect statement on consideration of bridge effects on the design water surface, clarification in Table 2 that the design water surface is the same as the NED plan, and an additional reference to historical practice in TM 3-424 (USACE 1956).

2. The following document is enclosed: Memorandum For Record, Subject: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED); NWK 2013 Underseepage Criteria; Revised per USACE-HQ Comments; dated 30 October 2014.

3. The Engineering Division point-of-contact is Mr. Jacob W. Owen, 816-389-3314. An indication of concurrence or non-concurrence is requested.

MEMORANDUM THRU CECW-NWD, Steven Kopecky

FOR Commander, US Army Corps of Engineers (CECW-CE\Robert Bank), 441 G Street NW, Washington, DC 20314-1000

SUBJECT: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED) Underseepage Criteria

1. This memorandum transmits for HQUSACE review and endorsement the final version of the proposed underseepage criteria for use on the Missouri River Levee System (MRLS) R471-460 & L455 levee projects.

2. We have had significant vertical teaming on the development of this criteria between NWK, NWD, HQUSACE and RMC personnel. The criteria incorporates comments included in a resolution document received from HQUSACE (Conforti) via email on 09 March 2015. Revisions to the criteria based on the resolution document were concurred with by RMC (Shewbridge) via email on 19 March 2015.

3. My Point of Contact for this memorandum is Mr. Scott Vollink, Levee Safety Program Manager and Acting Levee Safety Officer, (816) 389-3600, or Scott.D.Vollink@usace.army.mil.

MEMORANDUM FOR Deputy Commander, Northwestern Division, ATTN; CENWD-RBT (Joseph Kellett), 1125 NW Couch, Suite 500, Portland, Oregon 97209

SUBJECT: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED) Revised Underseepage Criteria; Document Transmittal for Major Subordinate Commander Approval

1. Purpose. This memorandum transmits for approval the final version of MRLS R 471-460 & L-455 PED Underseepage Criteria, revised per comments provided by USACE-HQ.

2. The following document is enclosed: Memorandum For Record, Subject: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED); NWK 2013 Underseepage Criteria; Revised per USACE-HQ Comments; dated 08 April 2015.

3. The Engineering Division point-of-contact is Mr. Jacob W. Owen, 816-389-3314.

4. An indication of concurrence or non-concurrence is requested.

MEMORANDUM FOR RECORD

SUBJECT: Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED); NWK 2013 Underseepage Criteria; Revised per USACE-HQ Comments

1. PURPOSE: The purpose of this memorandum is to document evolutions in levee underseepage criteria for the subject project and make recommendations for levee underseepage criteria for use in PED. This memorandum is considered an addendum to the 28 February 2011 Memorandum for Record, "Kansas City District Levee Underseepage Guidelines," that laid the groundwork for developing underseepage criteria for Kansas City District levees and floodwalls currently subject to study or PED. This memorandum is an update and replacement for the 14 February 2014 Memorandum for Record, "Missouri River Levee System (MRLS) R 471-460 & L-455 Pre-Construction, Engineering, and Design (PED); NWK 2013 Underseepage Criteria," and has been revised per USACE-HQ comments transmitted via email to CENWD on 21 July 2014 and subsequently transmitted via email to CENWK on 22 July 2014. The comments received were in draft memorandum format and included information regarding the forthcoming revised EM 1110-2-1913 Design, Construction, and Evaluation of Levees. CENWK acknowledges the information provided in the memorandum, generally concurs with the comments, and has updated the proposed criteria accordingly. Additional comments were received via email to CENWK on 30 January 2015. CENWK generally concurs with the comments, and has updated the proposed criteria accordingly. Although this addendum specifically applies to the subject project, the principles applied within this memorandum should be considered during the development of underseepage criteria for future projects within the Kansas City District pending finalization of the updated EM 1110-2-1913.

3. BACKGROUND: Underseepage criteria used to develop recommendations in the 2006 feasibility report for the subject project applied the "Kansas City District" underseepage criteria commonly in use at the time of the study is included within Table 1:

TABLE 1—UNDERSEEPAGE CRITERIA—2006 FEASIBILITY REPORT

CONDITION	FLOOD STAGE	MINIMUM GRADIENT SAFETY FACTORS	
		LEVEE TOE	UNDERSEEPAGE BERM TOE
LEVEE WITHOUT AN UNDERSEEPAGE BERM	TOP OF LEVEE	1.1	BERM NOT REQUIRED
LEVEE WITH AN UNDERSEEPAGE BERM	TOP OF LEVEE MINUS 3'	1.5	1.1

Since the 2006 feasibility report has been completed underseepage criteria within USACE has been in flux. Current USACE guidelines are contained in Engineer Manual (EM) 1110-2-1913 *Design and Construction of Levees*, 30 April 2000. New underseepage guidelines superseding many of the recommendations in EM 1110-2-1913 were published in Engineer Technical Letter (ETL) 1110-2-569 *Design Guidance for Levee Underseepage*, 1 May 2005. ETL 1110-2-569 stated that it would be rescinded when EM 1110-2-1913 was revised. EM 1110-2-1913 has not been revised, but the ETL officially expired in May 2010. A draft version

of revised EM 1110-2-1913, Appendix C - *Design of Seepage Berms* was issued for USACE internal review in October 2006 but was never finalized. EC 1110-2-6067 *USACE Process for the National Flood Insurance Program (NFIP) Levee System Evaluation*, 31 August 2010, states expired ETL 1110-2-569 should be used as a guide to evaluate levee structures and is the current USACE policy instead of the requirements in the current EM 1110-2-1913.

NWK, in the absence of published updated levee underseepage criteria, developed the 28 February 2011, CENWK-ED-GD Memorandum for Record, Subject: "Kansas City District Levee Underseepage Guidelines," that outlined the levee underseepage criteria shown in Table 2. NWK has used these criteria since signing of the memorandum.

Currently, a USACE team is working on a revision to EM 1110-2-1913 that is expected for release in the near future. NWK had representation at the EM revision kick off meeting, and has been communicating with the revision team on underseepage criteria over the last couple years in an attempt to ensure NWK underseepage criteria will be in line with future USACE recommendations.

TABLE 2—UNDERSEEPAGE CRITERIA—28 FEBRUARY 2011 NWK MEMORANDUM

CONDITION	MINIMUM GRADIENT SAFETY FACTORS (FLOOD STAGES ALL CASES WILL BE AT THE NED LEVEE CREST)	
	LEVEE TOE	UNDERSEEPAGE BERM TOE[1]
LEVEE WITHOUT AN UNDERSEEPAGE BERM	1.6	BERM NOT REQUIRED
LEVEE WITH AN UNDERSEEPAGE BERM	1.6	GRADUATED[2] SAFETY FACTORS OF 1.5 AT A DISTANCE OF 100' FROM THE LEVEE TOE TO 1.1 AT A DISTANCE OF 500' OR FURTHER FROM THE LEVEE TOE

1. The minimum underseepage berm width will be 100 feet.
2. The graduated factor of safety with berm width was an attempt to recognize that boil development at increasing distance from the levee toe is lower risk.

4. PED UNDERSEEPAGE CONTROL REVISITED: The NWK 2011 underseepage criteria were used to revise the feasibility study underseepage control for the subject project as part of PED. From the feasibility study to PED, average underseepage berm widths increased from 215 feet to 380 feet. The primary contributors to the underseepage berm width increases included: elevating the design flood stage to the levee crest, revisions to the Missouri River hydrology and hydraulic analysis completed during PED which raised the levee top profile approximately 0.5 feet, and the increased required berm toe safety factor

based on the NWK 2011 criteria. Berm thicknesses were less of an impact because a minimum berm thickness at the levee toe of 5 feet was applied during the feasibility study. Because of the large increases in the underseepage control requirements from feasibility to PED, and because these systems have performance histories during recent significant flood events, the Northwest Division (NWD) requested during a project briefing on 31 October 2013 that NWK revisit underseepage criteria for the subject project. NWD specifically requested the New Orleans District Hurricane and Storm Damage Risk Reduction (HSDRRS) underseepage criteria be considered. HSDRRS criteria are included within Table 3.

TABLE 3 —HSDRRS UNDERSEEPAGE CRITERIA

UNDERSEEPAGE BERM WIDTH DIVIDED BY LEVEE HEIGHT	MINIMUM GRADIENT SAFETY FACTORS			
	LEVEE TOE		UNDERSEEPAGE BERM TOE	
	DESIGN WATER SURFACE ELEVATION [1]	PROJECT GRADE WATER SURFACE ELEVATION [2]	DESIGN WATER SURFACE ELEVATION [1]	PROJECT GRADE WATER SURFACE ELEVATION [2]
LEVEE WITHOUT AN UNDERSEEPAGE BERM	1.6	1.3	BERM NOT REQUIRED	BERM NOT REQUIRED
4	1.6	1.3	1.5	1.2
8	1.6	1.3	1.3	1.1
12	1.6	1.3	1.1	1.0
16 OR MORE	1.6	1.3	1.0	1.0

1. Design water surface elevation is the project design water surface with a 90% confidence level.
2. Project grade is the top of levee and is higher than the design water surface elevation to account for wave action/runup minus the overbuild that is provided for primary consolidation

5. LEVEE PERFORMANCE DURING THE 2011 FLOOD EVENT: MRLS R 471-460 is 13.8 miles in length. Of the total length, 14.4% is earthen levee with no designed underseepage control, 4.8% is earthen levee with a combination of designed underseepage berm and pressure relief wells, and 80.8% is earthen levee with designed underseepage berms.

MRLS R 471-460 was loaded to 90% of the levee height during the 2011 flood event, which is approximately 1.5 feet of levee freeboard. During the flood event, 10% of the levee unit experienced sand boils. Of the portion of the unit that experienced sand boils, 13.7% occurred where there was no designed underseepage control and 86.3% occurred where there were designed underseepage berms. Approximately 17% of the sand boil areas were within low areas not accounted for during project design and landward ditches that eliminated

or thinned the blanket and increased the head between the river level and the landside ground surface. Generally, boils that occurred in reaches with underseepage berms occurred at berm toes.

Outside the MRLS 471-460 levee reaches exposed to sand boil activity, there were no functioning piezometers to determine underseepage pressures landward of the levee that could be used to assess performance or establish criteria for underseepage control design. However, observations of no underseepage distress can be used to assess reasonableness of underseepage analysis input parameters.

MRLS L-455 is 15.6 miles in length. Of the total length, 50.9% is earthen levee (except for about 100 feet of floodwall) with no designed underseepage control, 4.7% is earthen levee with a combination of a designed underseepage berm and pressure relief wells, and 44.4% is earthen levee with designed underseepage berms.

MRLS L-455 was loaded to 71% of the levee height during the 2011 flood event, which is approximately 4 feet of levee freeboard. During the flood event, 6.5% of the levee unit experienced sand boils. Of the portion of the unit that experienced sand boils, 7.0% occurred within reaches with no designed underseepage control, 3.7% occurred within reaches with combined underseepage berms and pressure relief wells, and 89.3% occurred within reaches with the designed underseepage berms. Approximately 54% of the observed sand boils occurred within landward ditches or a lake beach area that eliminated or thinned the blanket and increased the head because of a lower landside ground surface. Generally, boils that occurred in reaches with underseepage berms occurred at berm toes.

MRLS L-455 piezometers are located in the vicinity of a pressure relief well field and at locations downstream of the pressure relief well field. Generally, the piezometers indicated the levee performed as designed. However, in some areas the piezometric data and original blanket thickness did not correlate with the observed performance during the flood; i.e. boils were observed where they would not be expected based on the original design.

At locations of underseepage distress observed during the 2011 flood, underseepage berms were constructed as part of the post flood rehabilitation under PL 84-99.

The original design criteria for the subject project are shown in Table 4. Performance of the subject project during the 2011 flood is within reasonable expectations for a levee founded on alluvial deposits, loaded near the crest, with the shown underseepage criteria. Some boil activity would be expected at underseepage berm toes based on a minimum safety factor of less than 1.0.

TABLE 4—UNDERSEEPAGE CRITERIA—MRLS R 471-460 & L-455 ORIGINAL DESIGN CRITERIA		
CONDITION	MINIMUM GRADIENT SAFETY FACTORS (FLOOD STAGES ALL CASES WILL BE AT THE LEVEE CREST[1])	
	LEVEE TOE	UNDERSEEPAGE BERM TOE
LEVEE WITHOUT AN UNDERSEEPAGE BERM	1.5	BERM NOT REQUIRED
LEVEE WITH AN UNDERSEEPAGE BERM	1.5	0.8

[1]Levee Crest is the same as the Design Water Surface as defined in paragraph 6.c

6. UNDERSEEPAGE TELECONFERENCE: On 9 October 2013 a teleconference to discuss underseepage design and safety factors occurred with the following participants:

Dr. Scott Shewbridge, PE	Risk Management Center (RMC)
Jacob Owen, PE	Chief, ED-G
Glen Bellew, PE	Chief, ED-GD
Charles Detrick	ED-GD

Dr. Shewbridge was consulted because he is a contributor to the ongoing revisions of EM 1110-2-1913. The purpose of the teleconference was to get input on underseepage criteria being developed for the EM 1110-2-1913 revision. Below is a summary of the teleconference and the information discussed:

a. The history of the subject project (as described above in this memorandum) was presented to Dr. Shewbridge.

b. Dr. Shewbridge noted it appeared NWK was following an acceptable process and using criteria that are consistent with the current draft revisions of EM 1110-2-1913 for underseepage safety factors at the levee toe and using a design water surface at the levee crest.

c. In support of the flood stage placed at the levee crest for all analysis and design cases, Dr. Shewbridge stated the flood stage used in analysis and design should correspond to the stage that coincides with the National Economic Development (NED) Recommended Plan. This design stage will help ensure the levee performs consistent with the performance

assumed in economic analysis used to justify the project and meet performance expectations of stakeholders. This corresponds with the levee crest for the subject project. Dr. Shewbridge stated the levee crest elevation associated with estimated settlement and hydraulic superiority should not be included as part of the underseepage analysis.

d. New Orleans District is applying underseepage criteria to the HSDRRS that requires a gradient safety factor at the levee toe of 1.3 with water at the levee crest (project grade) and 1.6 with water at the "design water surface" for riverine systems. The difference between the design water surface and levee crest includes wave freeboard and overbuild for settlement. The case for a parallel application to the subject levee systems may be to apply a gradient safety factor of 1.3 with the flood stage at the levee crest and 1.6 with the flood stage at the "nominal" design flood event elevation (generally, approximately 3 feet below the levee crest for the subject project).

e. Dr. Shewbridge indicated deviating from recommended underseepage safety factors could be justified with such considerations as risk and uncertainty, consequences of failure, and life safety. It was noted the justification process may result in the safety factors remaining unchanged, increased, or decreased.

f. Because it is not practical to have high vertical gradient safety factors at underseepage berm toes, berm widths could be determined by addressing sand boil activity landward of the levee to ensure that seepage will not result in a progressive piping failure towards the levee embankment. This can be done by considering the Creep Ratio, or horizontal gradient, concept.

7. CREEP RATIO CONCEPT: The critical creep ratio concept is discussed in Bligh (1910) and Schmertmann (2000). Creep ratio is the ratio of seepage path length to total head. The seepage path length is the "length of creep." The total head is assumed to be dissipated along the length of creep. Horizontal gradient is the inverse of creep ratio. For the creep ratio concept, it is assumed there is an unfiltered seepage exit, such as would be the case through a sand boil. If an unfiltered exit is present and the creep ratio is less than the critical creep ratio (i.e., a seepage path too short for the applied head), backward erosion piping has a high likelihood of occurrence. The aforementioned references indicate critical creep ratios for silts and fine sands as shown in Table 5. The creep ratio concept can be applied to the base of a confining cohesive blanket overlying an artesian coarse grained aquifer, as is the typical levee foundation conditions in the lower Missouri River basin.

TABLE 5—CRITICAL CREEP RATIO BY REFERENCE		
REFERENCE	MATERIAL	HORIZONAL SEEPAGE CRITICAL GRADIENT, i_{h-c}
BLIGH (1910)	RIVER BEDS OF LIGHT SILT OR SAND OF WHICH 60% PASSESS THE 100-MESH SIEVE, AS THOSE OF THE NILE OR MISSISSIPPI RIVERS	1/18[1]
SCHMERTMANN (2000)[2]	SAND, $C_u = 1$	1/18
	SAND, $C_u = 2$	1/5
	SAND, $C_u = 3$	1/2.5
	SAND, $C_u = 4$	1/1.7

[1]value is considered "safe" according to literature and does not necessarily represent a limit state or critical value.
[2]See reference g. for data and equation relation between C_u and i_{h-c}, estimates are provided here for general reference.

8. UNDERSEEPAGE TOLERABLE RISK AND ECONOMICALLY OPTIMIZED CRITERIA: Subsequent to the 9 October teleconference, an exercise addressing Tolerable Risk Guidelines (obtained from the Best Practices in Dam and Levee Risk Analysis Manual, 2013) and construction cost was completed. The exercise compared expected performance and failure consequences to Tolerable Risk Guidelines and investigated underseepage control quantities and reliability for various underseepage criteria. The underseepage criteria assessed were 1) 2006 Original Feasibility, 2) 2011 NWK, and 3) HSDRRS.

Expected performance for the assessed underseepage criteria was evaluated based on annual initiation of underseepage failure (see section 9 for full failure description). A typical reach from the subject project was used for this exercise. The nominal hydraulic annual chance of exceedance (ACE) was multiplied by the probability of blanket rupture (failure initiation) for various water levels to determine the annual probability of failure initiation. The annual probability of underseepage failure initiation was determined using the methods described in ETL 1110-2-556. It should be understood that the annual probability of underseepage piping failure initiation will be higher than the annual probability of levee failure due to underseepage piping in nearly all situations. However, initiation is readily calculated with some degree of certainty and the other failure components are not (see section 9). Failure initiation at the levee toe is thought to be a reasonable, albeit high, estimate of the annual risk and a comparison can be made of the risk associated with various underseepage criteria for typical NWK levees. ETL 1110-2-556 considers initiation of underseepage piping failure and actual failure to be synonymous in the examples contained within. Life loss was

estimated using the Levee Screening Tool to determine the annualized life loss for levee failure based on various hydraulic loading scenarios. The annual probability of failure initiation was plotted versus the average incremental annual loss of life and compared to current Tolerable Risk Guidelines for dams. This information is shown in Figure 1. The 2011 NWK criteria plotted below Tolerable Risk Guidelines for failure initiation, and the other criteria plotted above Tolerable Risk Guidelines. This indicates a vertical gradient safety factor of 1.6 at the levee toe is a reasonable minimum for water at the levee crest, and a lower safety factor may not provide acceptable reliability for typical NWK levees. It is worth noting that riverine levees (Mississippi River and Tributary Levees – MR&T) within Mississippi Valley Division (MVD) where HSDRSS criteria is commonly used are significantly taller than NWK levees, and HSDRSS criteria may not have unacceptable risk when applied to MR&T levees and loading conditions. This is because the distance between the levee top and design water surface (typically 3 feet) may be 10% or less of the total levee height for a MR&T levee system. For a typical MR&T situation where the design water surface criteria control the underseepage design, there can only be a 10% higher load before overtopping. Consequently, the safety factor at the levee top will likely be higher than the allowable minimum and the risk of failure lower. For a typical NWK levee, that same 3 feet typically represents 15-30% of the total levee height. When the HSDRSS criteria is applied to NWK levees, the safety factor with water at the levee top is often near the allowable minimum.

Underseepage control quantities and probability of failure were compared for the assessed underseepage criteria on a typical levee section from the subject project to determine where diminishing returns are realized on construction cost vs. reliability. The annualized probability of failure was calculated as described in the preceding paragraph. The underseepage control quantities were based on designed underseepage berms for the various criteria. Figure 2 shows the results of the assessment: probability of failure versus construction quantities. The point on the curve where the slope begins to flatten would be equivalent to "optimized" criteria. From Figure 2, this location would be between the 2011 NWK and HSDRRS criteria; closer to HSDRRS than to 2011 NWK. This indicates that, only considering construction costs (quantities), the 2011 NWK criteria may be slightly "over" optimized. However, the 2011 NWK criteria do not appear to provide economically wasteful reliability when applied to the subject project.

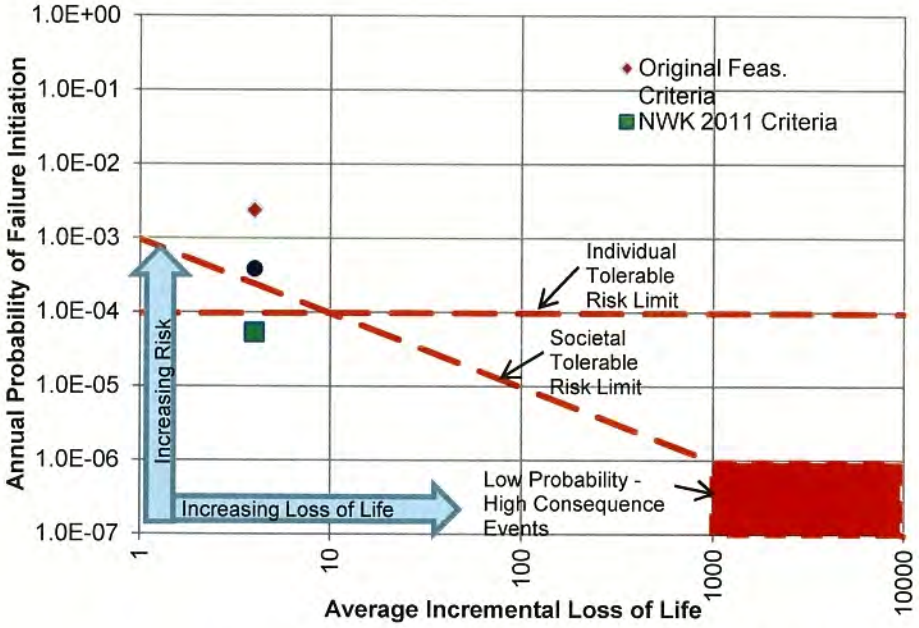

FIGURE 1—UNDERSEEPAGE CRITERIA TOLERABLE RISK GUIDELINES COMPARISON

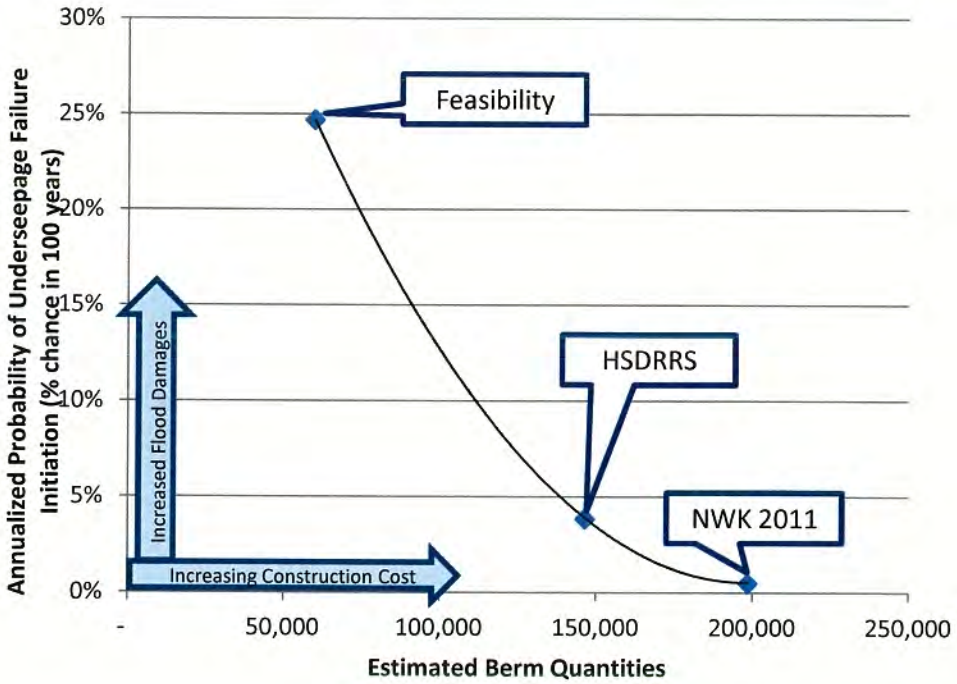

FIGURE 2—UNDERSEEPAGE CRITERIA QUANTITIES COMPARISON

9. LEVEE FAILURE BY UNDERSEEPAGE AND PIPING: The general understanding of levee failure by underseepage and piping when there is a fine grained blanket overlying a coarse grained aquifer is as follows:

a. Water elevations riverside of the levee increase, applying a differential head across the embankment and foundation, surcharging the coarse grained aquifer (artesian condition). (LOAD)

b. The artesian head in the aquifer is large enough to rupture/heave the fine grained blanket (critical vertical gradient is exceeded), creating a sand boil (unfiltered exit) in the fine grained blanket that allows sand to exit. (INITIATION)

c. The ratio of seepage path to total head (creep ratio) is such that movement of soil particles occurs through the unfiltered exit from along the interface between the fine grained blanket and coarse grained aquifer material. (PROGRESSION)

d. Movement of material continues along the blanket/aquifer interface and an erosion pipe is supported by the cohesive blanket material. (PROGRESSION)

e. There is no erosion pipe collapse or self healing to prevent progression of the pipe towards the levee riverside, and the pipe makes a direct connection with the river at the riverside toe. (CONTINUATION)

f. Successful intervention, consisting of initial observation of distress and subsequent flood fighting actions such as sand bag rings or emergency underseepage berms, does not occur to prevent failure. (INTERVENTION)

g. Gross enlargement of the pipe occurs, the levee collapses into the pipe resulting in a loss of freeboard, and the levee overtops and breaches. (BREACH)

The two critical conditions, early in the failure mechanism, are needed to result in levee failure. The first condition is the formation of an unfiltered exit by heave, or blow out, of the fine grained blanket. This condition is typically designed against by including a safety factor on vertical gradient through the blanket at the landside levee toe. The second condition is the presence of a horizontal gradient that will move foundation material along the seepage path and form an internal erosion pipe. Although, the requirement for a minimum total horizontal seepage length is a consideration in EM 1110-2-1901 Seepage Analysis and Control for Dams for the case of a pervious foundation with no downstream blanket (i.e., an unfiltered exit at the toe), and TM 3-424 (USACE 1956) discusses this concept for levee underseepage, horizontal gradients have not been a recent design consideration for levees except that long underseepage berms (> 400 ft) have been truncated because it was

recognized that long underseepage paths seldom lead to underseepage failure. However, underseepage berm widths could be determined with the expectation of sand boil development as long as there is reasonable assurance against foundation material movement. Furthermore, underseepage berms provide a longer seepage path for internal erosion and increase the likelihood of successful intervention. Intervention has been frequently used to prevent progression of seepage related failures in NWK throughout history. However, relying heavily on intervention during project design is not considered to be prudent given that intervention first requires observation. Early observation can be inhibited by landward vegetation, nightfall, and ponded water. Underseepage designs should provide a balance between expected levee performance, construction cost, and reasonable flood fight responses that are appropriate for the failure consequences.

10. NWK 2013 RECOMMENDED UNDERSEEPAGE CRITERIA: Sand boil development over a limited area landward of a levee should not be unexpected because of the nature of floodplain formation. Generally, the soil blanket is not uniform in alluvial deposits. By the nature of floodplain deposition, it is reasonable to expect variability, both in dimension and composition that cannot be fully defined with subsurface investigations. The empirical methods based on engineering principles adopted by the U.S. Army Corps of Engineers (current EM 1110-2-1913) acknowledge and account for blanket variability within the levee underseepage equations. The challenge is to discern from the available subsurface information the underseepage equation parameters that realistically represent the controlling floodplain features. It is neither practical nor economically feasible to account for each isolated change in the blanket, nor is it practical or economical to have large vertical gradient safety factors aimed at preventing any sand boil development landward of levees. Identifying isolated areas that require additional underseepage control beyond that established at the time of design and construction should occur as part of the project's performance via the "observational method" first described by Terzaghi and Peck. The emphasis of levee design should be to ensure stability near the levee toe while acknowledging manageable risk will permit reduced safety factors and limiting underseepage berm widths some distance away from the levee embankment. The recommended underseepage criteria in this memorandum were established with this philosophy.

As an addendum to Kansas City District Levee Underseepage Guidelines, 28 February 2011 Memorandum for Record, the recommended underseepage analysis and design safety factors for the MRLS R 471-460 and L-455 PED, and similar future projects, will consist of the following:

a. Flood Stage: The flood stage for all cases will be the elevation of the levee's physical crest elevation at the top of the impervious cap, excluding overbuild for settlement, transition structures, etc as discussed in paragraph 6.c.

b. Vertical Gradient and Creep Ratio: Both vertical gradients and creep ratios should be considered in design. Design objectives for levee toes are to have comparatively high vertical gradient safety factors such that an unfiltered exit is unlikely to occur at the levee toe. As such, the creep ratio is not a consideration for the levee toe. Conversely, design objectives for underseepage berm toes are to have comparatively low vertical gradient safety factors such that an unfiltered exit is more likely, or even expected, to occur. The creep ratio will be considered in determining minimum underseepage berm widths such that progression of the seepage condition beyond sand boil formation is not likely to occur. However, creep ratio should not be solely relied upon to determine reliable levee performance.

The critical vertical gradient is equal to the soil effective unit weight divided by the unit weight of water. The current guideline for $i_{h\text{-}c}$ is located in Schmertmann (2000). The fine sands located directly beneath the overlying fine grained blanket in the Missouri River floodplain have a typical C_u greater than 2.0. As such, initial designs without available laboratory grain size testing should assume a critical horizontal gradient of 1/5 until laboratory data can be obtained. The horizontal seepage length is defined as the distance from the effective seepage entrance to the first exit point for seepage at the landward toe of the underseepage berm, or $X_1 + L_2 + dxW$. The total head, H, should be measured from the water loading elevation to the landside ground surface.

The required vertical gradient safety factor ($FS_{i\text{-}v}$) and ratio of critical horizontal gradient ($i_{h\text{-}c}$) to in situ horizontal gradient (i_h) are included within Table 6. Underseepage berms should be designed to meet the vertical gradient safety factor with a generally recommended minimum berm width of 150 feet for new levee projects. A minimum berm width of 150 feet has been long standing practice in NWK to relocate the seepage concentration point away from the levee toe when berms are required. For modifications to levees with significant and meaningful performance data that increases the confidence in subsurface conditions, such as this project, reduction of the recommended minimum berm width could be considered. At any location with an $FSi_{\text{-}v}$ less than 1.6, $i_{h\text{-}c}/i_h$ and failure likelihood shall be considered in the risk assessment framework (Section 9) to ensure acceptable risk. A graphical representation of the underseepage criteria is included in Exhibit 1.

The underseepage stability considerations at features such as landward ditches, landward free exits such as oxbow lakes, and other features should be considered separately based on vertical seepage gradient safety factors and creep ratio concepts as appropriate to ensure satisfactory performance. These considerations and analyzed features should be fully documented in the design documentation for the project using similar criteria as recommended for underseepage berms. These considerations and analyzed features should be fully documented in the design documentation for the project using similar criteria as recommended for underseepage berms.

Additional discussion in support of the recommendations in Table 6 follows:

(1) There is considered sufficient reliability at the levee toe with the minimum required vertical seepage gradient safety factor to not require consideration of horizontal seepage gradient concepts. A vertical seepage gradient safety factor of 1.6 is approximately a gradient of 0.5. This was shown to be the lower bound of sand boil formation based on flood observations documented in WES TM 3-424, further indicating this is generally a reliable condition.

TABLE 6 —MRLS R 471-460 & L-455 PED UNDERSEEPAGE CRITERIA

CONDITION	MINIMUM GRADIENT REQUIREMENTS			
	LEVEE TOE		UNDERSEEPAGE BERM TOE[1]	
	FS_{i-v}	i_{h-c}/i_h	FS_{i-v}	i_{h-c}/i_h
LEVEE WITHOUT UNDERSEEPAGE BERM	1.6	N/A	N/A	N/A
LEVEE WITH UNDERSEEPAGE BERM	1.6[1]	N/A	1.0	1.6

1. The minimum underseepage berm thicknesses at the levee toe and the underseepage berm toe will be 3 feet and 1 foot, respectively. Thicknesses will be adjusted sufficiently to account for settlement and post construction activity. Berms shall be graded for positive drainage away from the levee

(2) The recommended minimum vertical seepage gradient safety factor requirement through the natural blanket at the underseepage berm toe (FS = 1.0) is reasonable and based on the NWK design and performance experience on the subject and other levee performance throughout the Lower Missouri River. Vertical seepage gradient safety factors of 1.0, and as low as 0.8, have been used at the toe of long underseepage berms successfully with the general acknowledgement that there is manageable risk as the distance increases landward of the levee. However, it should not be common engineering practice to

set general criteria guidelines below a "failure" limit state. As such, a value below 1.0 was not considered as a general design guide.

(3) Horizontal seepage concepts are not easily analyzed by analytical models. Horizontal gradients that may lead to continued internal erosion are generally based on observed field performance and laboratory experiments. However, horizontal gradient concepts are still considered important in establishing minimum underseepage berm widths based on total horizontal seepage length.

(5) Typically, levees within NWK are 10-20 feet in height. Minimum berm widths, thicknesses, and required safety factors at berm toes recommended in this memorandum are considered appropriate for NWK and may not apply to other USACE districts with generally larger levees or different foundation conditions.

(6) For future projects, a risk assessment to determine the adequacy of design criteria reliability for the consequences and uncertainty in subsurface conditions should be performed. The risk assessment should consider the full failure event tree. Intervention effectiveness should not be considered in establishing design critiera without careful consideration of future resources. If intervention effectiveness is largely used to justify a design variance, the anticipated intervention shall be well documented in the DDR and OMRR&R Manual.

11. CONCLUSIONS: The recommended design approach and safety factors outlined within this memorandum will be applied to the MRLS R 471-460 & L-455 PED underseepage analysis and design. The design analysis, safety factors, and required underseepage control will be documented within the project's Engineering Documentation Report (EDR) and the Design Documentation Report (DDR). Additionally, the underseepage design recommendations for the subject project are recommended for initial designs of similar NWK projects in the future, pending consideration of a revised EM 1110-2-1913, at such time it is issued. The adequacy of all future new levee designs and levee modification designs should be subject to a full risk analysis based on expected life safety consequences, for all potential failure modes and water levels in accordance with the forthcoming update to EM 1110-2-1913 and finalization of EC 1110-2-6072 Levee Safety Program – Policy and Procedures. The use of typical failure initiation and progression concepts to develop criteria should better ensure proposed solutions are not over/under conservative or based on arbitrary limits. Any deviation from the recommended criteria should be well documented in project design documentation, based on sound engineering reasoning and should consider the general failure mode described in this memorandum. All performance expectations should be well documented in design, operations, and maintenance documents.

12. Point of contact for this memorandum is Glen Bellew (816-389-3553).

NOMENCLATURE:

H = NET HYDROSTATIC HEAD (RIVER SURFACE ELEVATION - TAILWATER ELEVATION)
L_2 = LEVEE BASE WIDTH
w = UNDERSEEPAGE BERM WIDTH
t = UNDERSEEPAGE BERM THICKNESS AT THE LEVEE TOE
z_{bl} = BLANKET THICKNESS (SILT, CLAY, OR COMBINATION; LESS PERVIOUS THAN FOUNDATION SANDS)
x_1 = DISTANCE FROM EFFECTIVE SEEPAGE ENTRY TO RIVERSIDE LEVEE TOE
HGL = HYDRAULIC GRADE LINE (AT MIDDEPTH OF FOUNDATION SANDS) BENEATH THE LEVEE
γ' = BLANKET EFFECTIVE UNIT WEIGHT
γ_w = WATER UNIT WEIGHT
h_o = EXCESS HYDROSTATIC HEAD AT THE LEVEE TOE
h_w = EXCESS HYDROSTATIC HEAD AT THE UNDERSEEPAGE BERM TOE
FS_{iv} = VERTICAL GRADIENT SAFETY FACTOR
i_v = VERTICAL GRADIENT
i_h = HORIZONTAL GRADIENT
$i_{h\text{-}c}$ = HORIZONTAL GRADIENT

NOTES:

MINIMUM UNDERSEEPAGE BERM THICKNESS AT LEVEE TOE IS 3 FEET AND AT BERM CROWN IS 1 FOOT
BERMS SHALL BE GRADED WITH POSITIVE DRAINAGE AWAY FROM THE LEVEE
MINIMUM BERM WIDTH FOR NEW LEVEES SHALL BE 150 FEET
EXCESS HEAD CALCULATIONS TO BE PERFORMED IN ACCORDANCE WITH EM 1110-2-1913

REQUIRED SAFETY FACTORS:

LEVEE TOE:

$$FS_{iv} = \frac{\gamma'/\gamma_w}{(h_o - t)/(z_{bl} + t)} \geq 1.6$$

UNDERSEEPAGE BERM TOE:

$$FS_{iv} = \frac{z_{bl} * \gamma'}{h_w * \gamma_w} \geq 1.0$$

$$i_h = \frac{H}{X1 + L2 + W}$$

$i_{h\text{-}c}$ BASED ON COEFFICIENT OF UNIFORMITY OF PIPING LAYER FROM SCHMERTMANN (2000)

$$\frac{i_{h\text{-}c}}{i_h} \geq 1.6$$

District Underseepage Guidance

(Used for permeability ratios on page 4)

UNDERSEEPAGE

1. General. The need for underseepage control is determined from a study of the thickness and characteristics of the natural blanket material, the thickness and permeability of the foundation sands, the effective seepage entrance and exit, and the maximum differential head on the levee created by the design water surface. Seepage enters the foundation sands beneath the levee through the bed of the river and through the foreshore blanket. This results in a hydraulic gradient and an artesian head at the base of blanket as the water flows from the riverward to the landward side of the levee. The pressures that develop landward of the levee during sustained flood stages may, unless controlled, cause heaving or rupture of the blanket in thin blanket areas resulting in a concentration of seepage flow and the formation of sand boils and potential levee failure. Relief wells, underseepage berms or other measures should be considered to control the effect of underseepage pressures in the permeable sands below the impervious blanket.

2. Guidance. Where applicable the seepage modeling techniques addressed within the appendices of EM 1110-2-1913, “Design and Construction of Levees” may be used by the designer. The techniques addressed are commonly used to determine the hydrostatic pressures landward of the levee and may also be used in design of underseepage berms and in calculating pressures to be used in structural uplift.

3. District Specific Guidance. The Kansas City District method of estimating the underseepage gradient and the required factors of safety are slightly different than the method and factors of safety presented in the EM 1110-2-1913 and are based on the conclusions of a Corps of Engineers, Missouri River Division Conference, held in Omaha in 27 November, 1962. The underseepage analysis and design recommendation are based on experience on the Missouri River during the flood of 1952. The procedure addressed is applicable when the impervious blanket is considered infinite in extent landward of the levee toe.

4. Tools. Groundwater model programs may be used for calculating underseepage and gradients, but the designer should confirm the model is applicable to the condition being modeled. Another tool, which may be used when addressing seepage issues, is the traditional flow net.

5. Calculations of the underseepage factors of safety. The factors of safety to be used in underseepage analysis are as follows:

5.1. The gradient (piping) factor of safety is defined as:

$$F_s = \frac{\gamma_b * z}{h * \gamma_w} = \frac{i_c}{i}$$

where:

F_S = gradient factor of safety
γ_b = buoyant weight of the saturated soil
γ_w = unit weight of water
z = thickness of impervious blanket
h = excessive piezometer head above ground surface acting on base of blanket
i = actual gradient (h/z)
i_c = critical gradient when flotation occurs, determined as follows:

$$i_c = \frac{\gamma_b}{\gamma_w}$$

The following factors of safety should be used:

$F_S \geq 1.1$ at the toe of levee with the river at the top of levee when evaluating for need for underseepage control.

$F_S \geq 1.5$ at the toe of the levee with the river at the design water surface (generally 3 feet below top of levee for urban levees). Designer should confirm actual design with the U.S. Army Corps of Engineers, Local Protection Section when designing underseepage control.

$F_S \geq 1.1$ at the toe of the underseepage berm with the river at the design water surface when designing underseepage control, for urban levees.

$F_S \geq 0.8$ at the toe of the long underseepage berm with the river at the design water surface when designing underseepage control, for agricultural levees.

$F_S \geq 1.5$ at the bottom of excavations (permanent or temporary) for excavations landward of the flood control projects, considering the river at the design elevation.

$F_S \geq 1.5$ at the mid-point between pressure relief wells in the instances when the underseepage is controlled by relief wells, considering the river at the design elevation.

$F_S \geq 1.5$ at the levee toe if the underseepage is not controlled by an underseepage berm, considering the river at the design elevation (a factor of safety of 1.1 should be obtainable approximately 200 feet landward of the levee).

If the geotechnical information obtained for the proposed project indicates different field conditions than the initial conditions used for the levee design, a back calculation will be necessary to determine the actual underseepage factors of safety. Any proposed construction should not worsen the existing condition of the levee and should be calculated based on the actual factors of safety obtained in back calculations. Different field conditions can occur if the blanket was eroded and the thickness reduced after flood events, if the distance from the riverside toe of the levee was reduced due to erosion of the riverbank, or the material in the blanket has been eroded and sand deposits replaced the natural impervious blanket after flood events.

5.2. Uplift Factor of Safety. In the special condition where the landward blanket is continuous, impervious, and relatively thick (greater than 10 feet), the designer should also check for uplift

of the blanket in accordance with structural guidance for uplift of a structure or pipe. The gradient factor of safety should also be checked when checking for uplift.

5.3 Heave Factor of Safety in Excavations. At the bottom of temporary or permanent excavations, heave occurs under conditions of high hydraulic gradient, when the seepage force due to differential head equals the overlying total weight of soil. The factor of safety against heave ≥ 1.5 for river stage at the design elevation is required and is defined as follows.

$$F_s = \frac{\Sigma(\gamma_t * D_t)}{\gamma_w * (h + D_t)}$$

where:

$F_{S.}$ = Factor of safety against heave at the bottom of the excavation

γ_t = Total unit weight of each soil layer below the excavation and above the pervious

D_t = Thickness of each soil layer below the excavation and above the sand

γ_w = Unit weight of water

h = Differential total head or net head at the analyzed location considering the river at the design elevation, above the existing top of ground in the excavation

6. Special Conditions. There is a special condition of basins and other permanent excavations constructed within the critical area landward of the levee. The seepage should be addressed both from river to basin or excavation and from basin or excavation to river.

6.1 Seepage from a permanent excavation landward of the flood protection structure (basin or ditch) should be considered in design. The factors of safety should be determined at the riverside toe of a levee considering the water elevation in the basin or ditch at the normal operation and the basin or ditch without impervious features. For this conditions, the following factors of safety are acceptable:

a. Piping (gradient) factor of safety: $F_S = 1.5$

b. Uplift factor of safety : Fs = 1.5

c. Heave factor of safety: $F_S = 1.5$

7. Kansas City District Method of Analysis. Figure UNDERSEEPAGE ANALYSIS shows a simplified cross section, with nomenclature and design data to be used in the underseepage analysis shown in the subsequent pages. The landward ground surface is generally assumed to be saturated and therefore used as the tailwater elevation. The permeability ratio represents the horizontal permeability of the pervious aquifer divided by the vertical permeability of the blanket material. The recommended basis for the selection of permeability ratios for use in the underseepage study is as follows:

Blanket Material	Assumed Permeability Ratio, K_f/K_b
SM	100
ML	200 - 400
ML-CL	400
CL	400 - 600
CH	800 - 1000

K_f = the horizontal permeability of the pervious substratum;
Kb = the vertical permeability of the blanket above the pervious substratum;

7.1 Seepage Quantities. The natural seepage per unit length of levee is determined using the equation:

$$Q = \$ * K_f * H$$

where:

Q = seepage per unit length of levee;
$\$$ = shape factor depending on the dimensions of the generalized cross section of the levee and foundation, the characteristics of the top stratum both riverward and landward of the levee, and the pervious substratum;

$$\$ = \frac{D_f}{L_1 + L_2 + L_e}$$

L_1 = effective length of the riverside blanket
L_2 = base width of the assumed impervious fill and natural blanket beneath it
L_e = distance from the landside toe of the assumed impervious section to the effective seepage exit
H = the net head on the levee.

8. Recommended references:

The following references contain details regarding COE requirements for the underseepage analysis within the critical area of a flood control project constructed by the COE.

8.1. EM 1110-2-1913, Design and Construction of Levees includes the following:

a. Necessary subsurface investigations and laboratory testing to obtain the geotechnical properties necessary for underseepage analyses.
b. Seepage control, including foundation underseepage and seepage through embankments.
c. Appendix B "Mathematical Analysis of Underseepage and substratum Pressure" establishes the method of underseepage analysis, the assumptions and the determination of factors involved in the analysis for different cases.

8.2. EM-1110-2-1901 “Seepage Analysis and Control for Dams”, includes the following:

a. Necessary subsurface investigation for determination of soil parameters for groundwater analysis.
b. Determination of permeability of soils in the foundation.
c. Seepage principles, including seepage forces, hydraulic gradients and uplift pressure.
d. Seepage conditions in the presence of relief wells, including well design.
e. Seepage control in earth foundation adjacent to structures, and remedial seepage control.

NOMENCLATURE AND EXPLANATIONS

(For Figure 1 UNDERSEEPAGE)

H = Total head on levee

D_{bR} = Thickness of natural blanket riverward of levee

D_{bL} = Thickness of natural blanket landward of levee

D_f = Thickness of natural pervious foundation

k_{bR} = Permeability coefficient in a vertical direction of the natural blanket riverward of levee

k_{bL} = Permeability coefficient in a vertical direction of the natural blanket landward of levee

k_f = Permeability coefficient of the pervious foundation

L_R = Actual length of the of the riverside natural blanket

L_L = Actual length of the of the landside natural blanket

C = Effective length of the pervious foundation of infinite length covered by a natural impervious blanket

$$C = \sqrt{D_f * D_b * \left(k_f / k_b\right)}$$

k_f/k_b = Permeability ratio between horizontal permeability of the permeable foundation and vertical permeability of the impervious natural blanket

L_1 = Effective length of the riverside blanket

$$L1 = C_r * \frac{e^{\left(2 * L_R / C_R\right)} - 1}{e^{\left(2 * L_R / C_R\right)} + 1}$$

L_2 = Base width of the assumed impervious fill and natural blanket beneath it.

L_e = Distance from the landside toe of the assumed impervious section to the effective seepage exit

$$Le = C \quad when \quad L_L = \infty \text{ and Le } = L_L \text{ when } L_L < C$$

γ_s = Saturated unit weight of the natural blanket

γ_w = Unit weight of water

i_c = Critical or maximum upward seepage gradient through natural blanket

$$i_c = \frac{\gamma_s - \gamma_w}{\gamma_w}$$

h_o = Head above tailwater at landside levee toe

$$h_o = \frac{H * L_e}{L_1 + L_2 + L_e}$$

i_o = Upward seepage gradient through natural blanket

$$i_o = \frac{h_o}{D_{bL}}$$

F_{Si0} = Gradient factor of safety at the toe of the levee

$$F_{Sio} = \frac{i_c}{i_o}$$

W_T = Trial berm width
$W_{T/2}$ = One half width of the berm
$H_{(WT/2)}$ = Head above tailwater at midpoint of underseepage berm

$$H_{(W_{T/2})} = \frac{H * L_e}{\left(\left(L_1 + L_2 + L_e\right) + W_{T/2}\right)}$$

x = Location where uplift has to be calculated
h_x = Head above tailwater at location where uplift has to be determined

$$h_x = \frac{h_o}{e^{\left(x / x_L\right)}} \quad where \quad x_L = L_e$$

$H_{(WT)}$ = Head above tailwater at end of underseepage berm

$$H_{(WT)} = \frac{H_{(W_{T/2})}}{e^{(W_{T/2}/c)}}$$

$i_{(wT)}$ = Upward seepage gradient through natural blanket at the end of berm

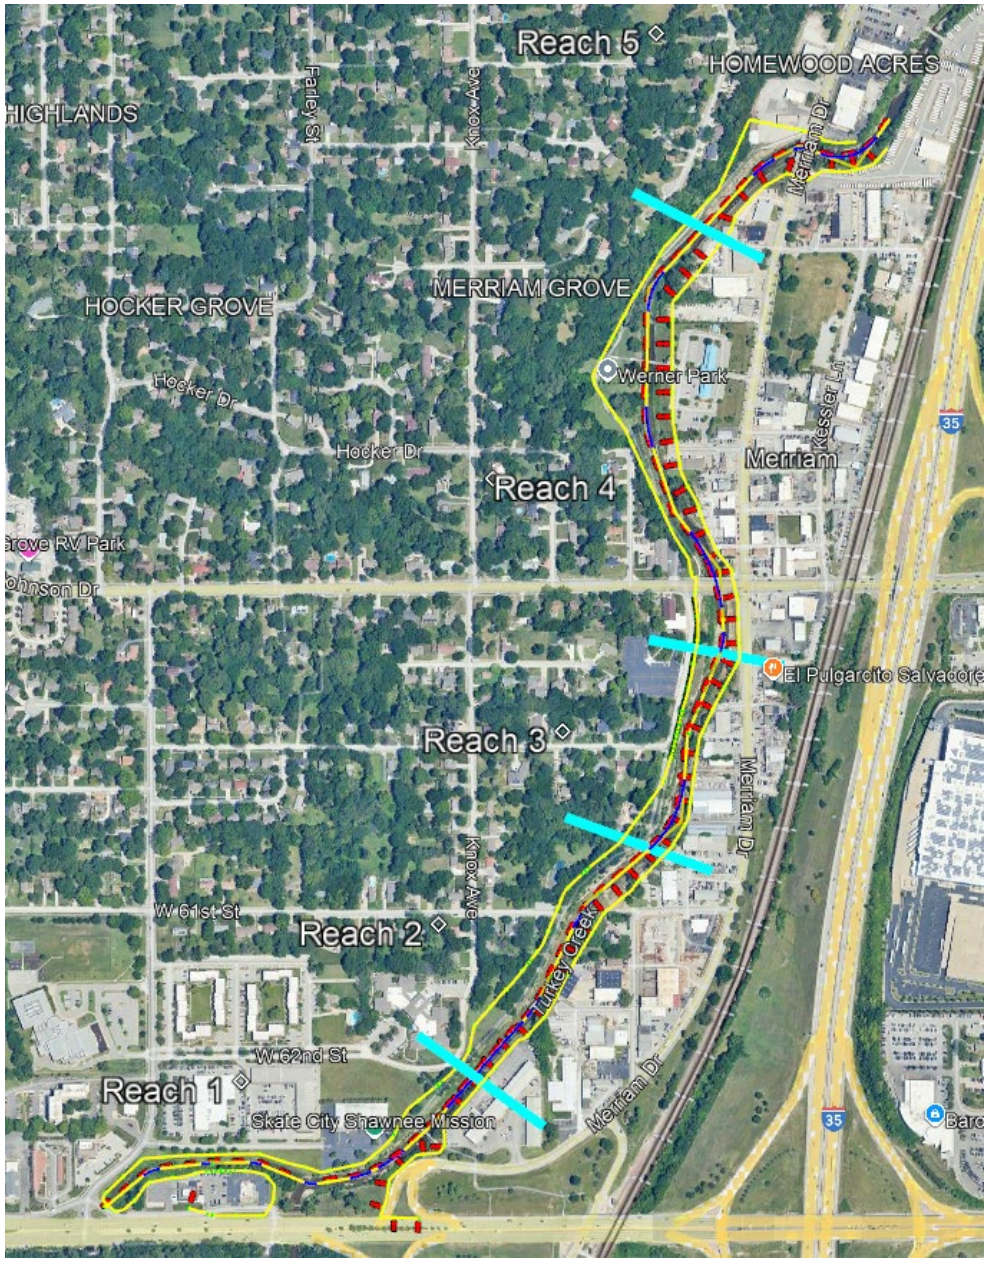
$$i_{(WT)} = \frac{H_{(WT)}}{D_{bL}}$$

$FSi_{(WT)}$ = Gradient Factor of safety at the end of the berm
L = Distance from effective seepage entry to effective exit.
M = Slope of hydraulic grade line beneath levee

APPENDIX B.2 – GLOBAL SLOPE STABILITY

Levee and Floodwall Slope Stability Calcs

General



The levee was divided into representative reaches for analysis based mainly on top of bedrock elevation. Soil stratigraphy and site geometry, including distance from the levee system alignment to the creek, were relatively consistent throughout the system while depth to bedrock increased from upstream to downstream (south to north). In general, the cross section with the tallest levee or floodwall was analyzed within a particular reach. Bottom of blanket elevations and top of bedrock elevations for design cross sections are based on the nearest borings or interpolated between borings.

Reach	UTC Centerline Stationing
1	0+00 to 17+60
2	17+60 to 29+50
3	29+50 to 38+60
4	38+60 to 57+80
5	57+80 to 66+00

General

Underseepage analysis performed for tallest levees and floodwalls within each reach based on August 2025 alignment.
Representative cross sections selected for stability analyses

Alignment is being refined but general levee/floodwall heights and soil conditions analyzed should be representative.

General

Existing Topography – Used Google Earth kmz file with topographic survey information prepared by EDG-C.

Levee Cross Section – Used 10-foot crest width and 1V:3H side slopes

Floodwall Cross Section – Used design footing widths

Levee Subsurface Profile – Developed representative soil profiles for each reach. As described in DDR text, developed a pervious zone thickness for a worst-case scenario, lowering top of the relatively impervious bedrock layer in the model to account for seepage through gravelly clays or joints or voids in bedrock.

SEEP/W Boundary Conditions – A water total head equal to the top of new levee is applied on the riverward slope, and a water total head equal to the landside grade is applied to the landside edge of the model. A potential seepage face is applied to the landward levee slope with water rate equal to 0 ft^3/sec, and a no-flow boundary is placed at bedrock with a water rate equal to 0 ft^3/sec.

Riverward Extent of Model – The model was extended at least halfway into Upper Turkey Creek.

Landward Extent of Model – Taken to 500 to 2000 feet landward of the new levee centerline. Extending the boundary farther appears to have no influence on the calculation results.

Hydraulic Conductivity of Sand – Used 0.003 ft/sec. This value is typically used for NWK levees such as the Argentine Levee Raise on the Kansas River (see Argentine DDR), the floodwall modification project at South Topeka on the Kansas River (see South Topeka DDR), and for design of Missouri River levee L-476 (see DM-1, p. I-15). This is also within the typical range used in Das Principles of Geotechnical Engineering, Table 5.1, p. 164, 1998.

Underseepage Calibration – A permeability ratio of K_f/K_b of 400 typical of ML-CL materials was used in the underseepage blanket theory spreadsheet. This equates to hydraulic conductivity of 7.5e-06 ft/sec for impervious blanket (K_b), using 0.003 ft/sec for sand (K_f). This was the starting point for saturated horizontal hydraulic conductivity. Each individual cross section was then calibrated to the blanket theory spreadsheet by adjusting the saturated horizontal hydraulic conductivity for impervious blanket and impervious fill in SEEP/W until the water total head at the landside toe matched the blanket theory spreadsheet.

Soil Strengths – See discussion in DDR

Levees

Performed calcs for four representative levee sections:
LB R1 L 26+80/UTC 14+50
LB R3 L 44+40/UTC 31+80
RB R2 L 18+20/UTC 26+80
RB RW L 41+40/UTC 49+50

Detailed example provided for LB R3 L 44+40/UTC 31+80
Major inputs and all results provided for other sections
(See Google Earth file, underseepage spreadsheet, and
GeoStudio files in project file for additional information)

L2 (levee width) = levee height from profile spreadsheet x 3 for 1V:3H slope x 2 for each side + 10' crest width

L2 = 7.387'*3*2 +10 = 54.322, say **54'**

Assume half of L2 on each side of centerline for showing landside and riverside levee toes

L1 (riverside seepage length) is distance from riverside levee toe to Turkey Creek (assuming no significant continuous pervious zone exposed on riverside of levee) = **40'**

Use survey topo and line distances in Google Earth to develop cross section for stability calcs

	Pervious	Mohr-Coulomb	115	0	31	0	

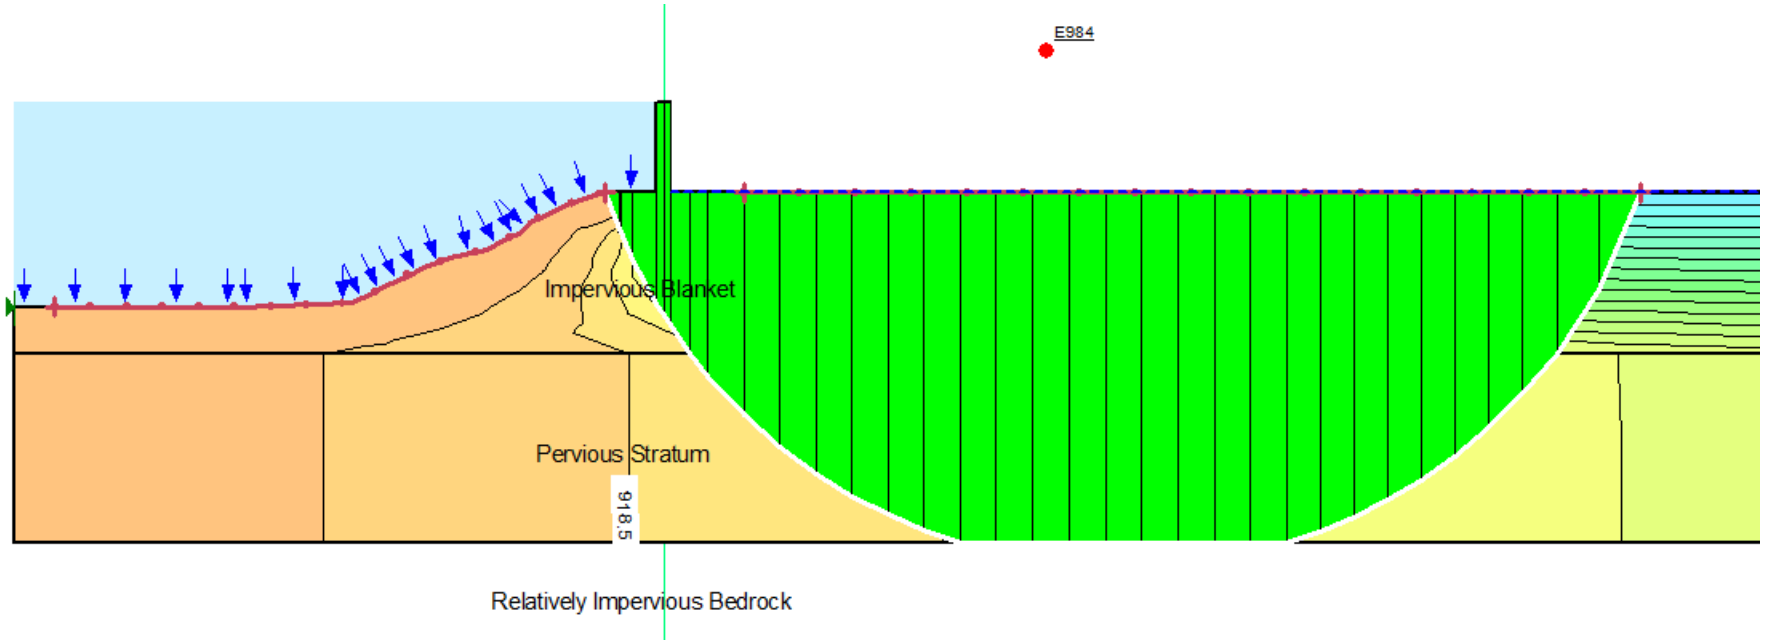
RB F 33+80/UTC 41+75 SLOPE/W Steady State Results

No feasible failure surface could be determined based on the soil conditions, shallow bedrock, and lack of downward slope on the landside
Steeper slopes or cracks resulted in same error message.

Error message for auto-selected critical failure surface (shown)

Error 984: Slip surface intersects vertical/overhanging bedrock or weak surface, contains air gap, bedrock, or weak surface



Error messages for other slip surfaces

Error 998: Slip surface enters or exits beyond specified slip surface limits

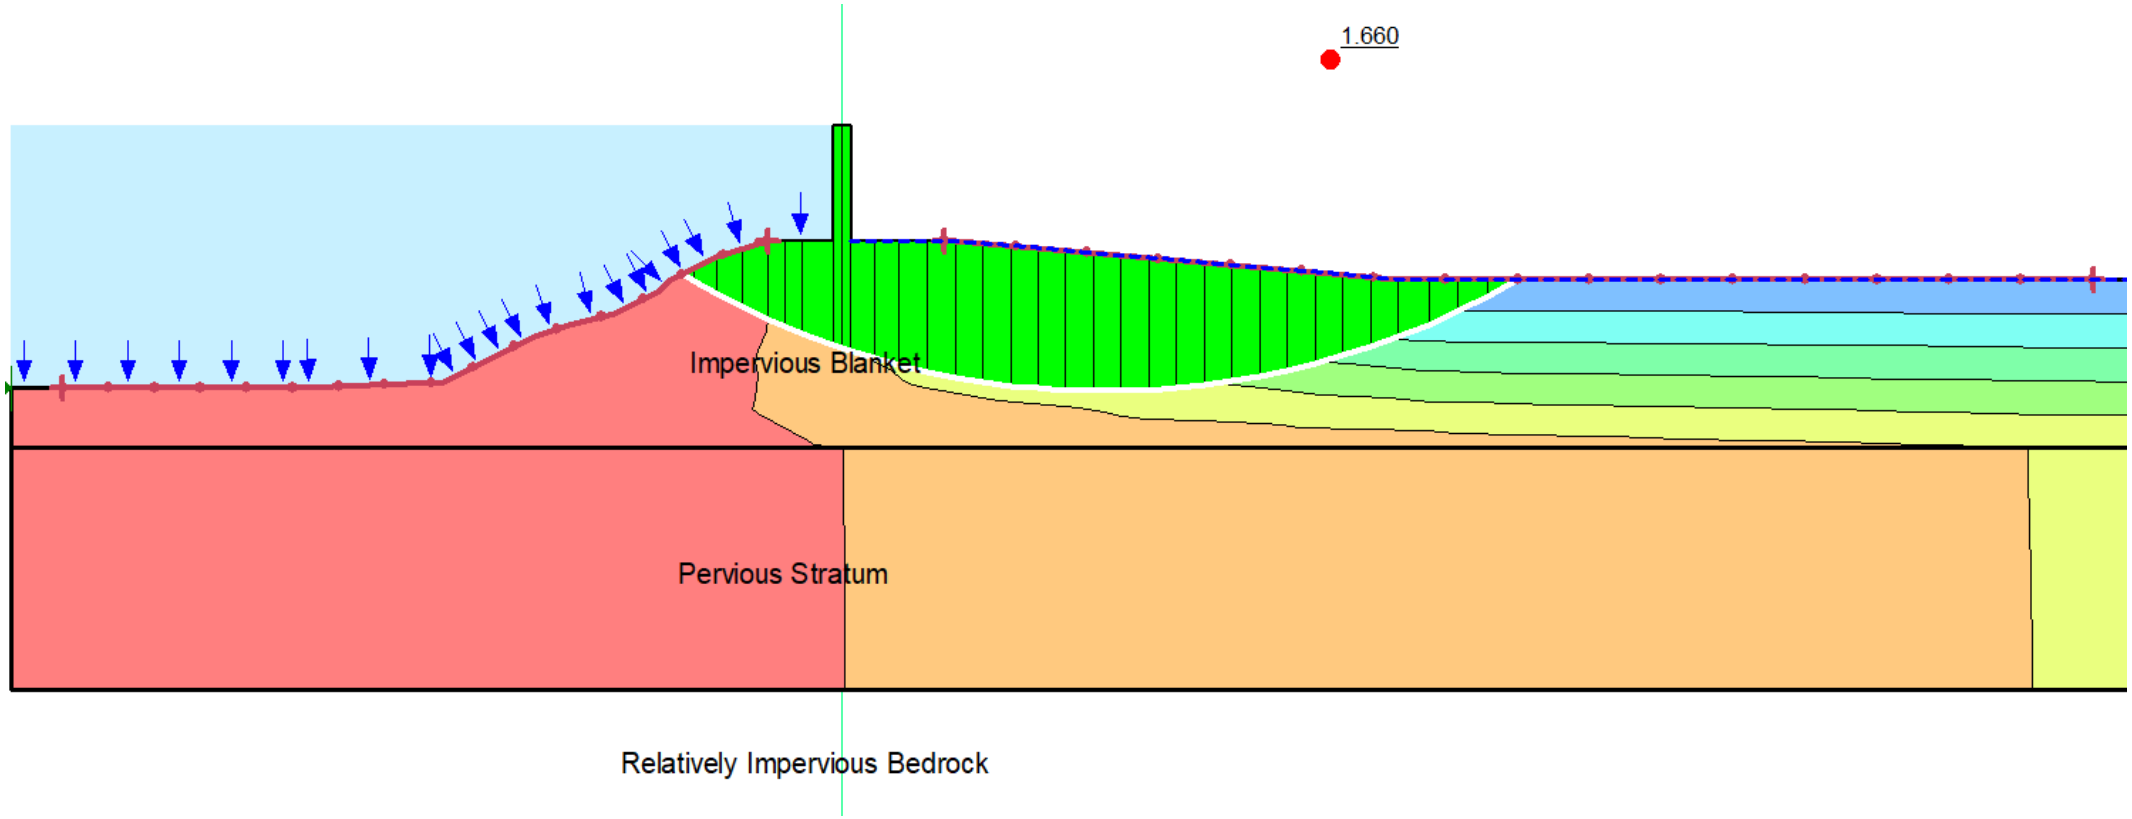
Error 996: Slip surface direction of movement is opposite to specified direction

Error 993: Slip surface is shallower than defined minimum depth

RB F 33+80/UTC 41+75 SLOPE/W Steady State Results

Analyzed with a landside slope rather than the existing flat landward surface in order to find a feasible slope failure surface

With this more conservative slope, FS is still greater than 1.4 required

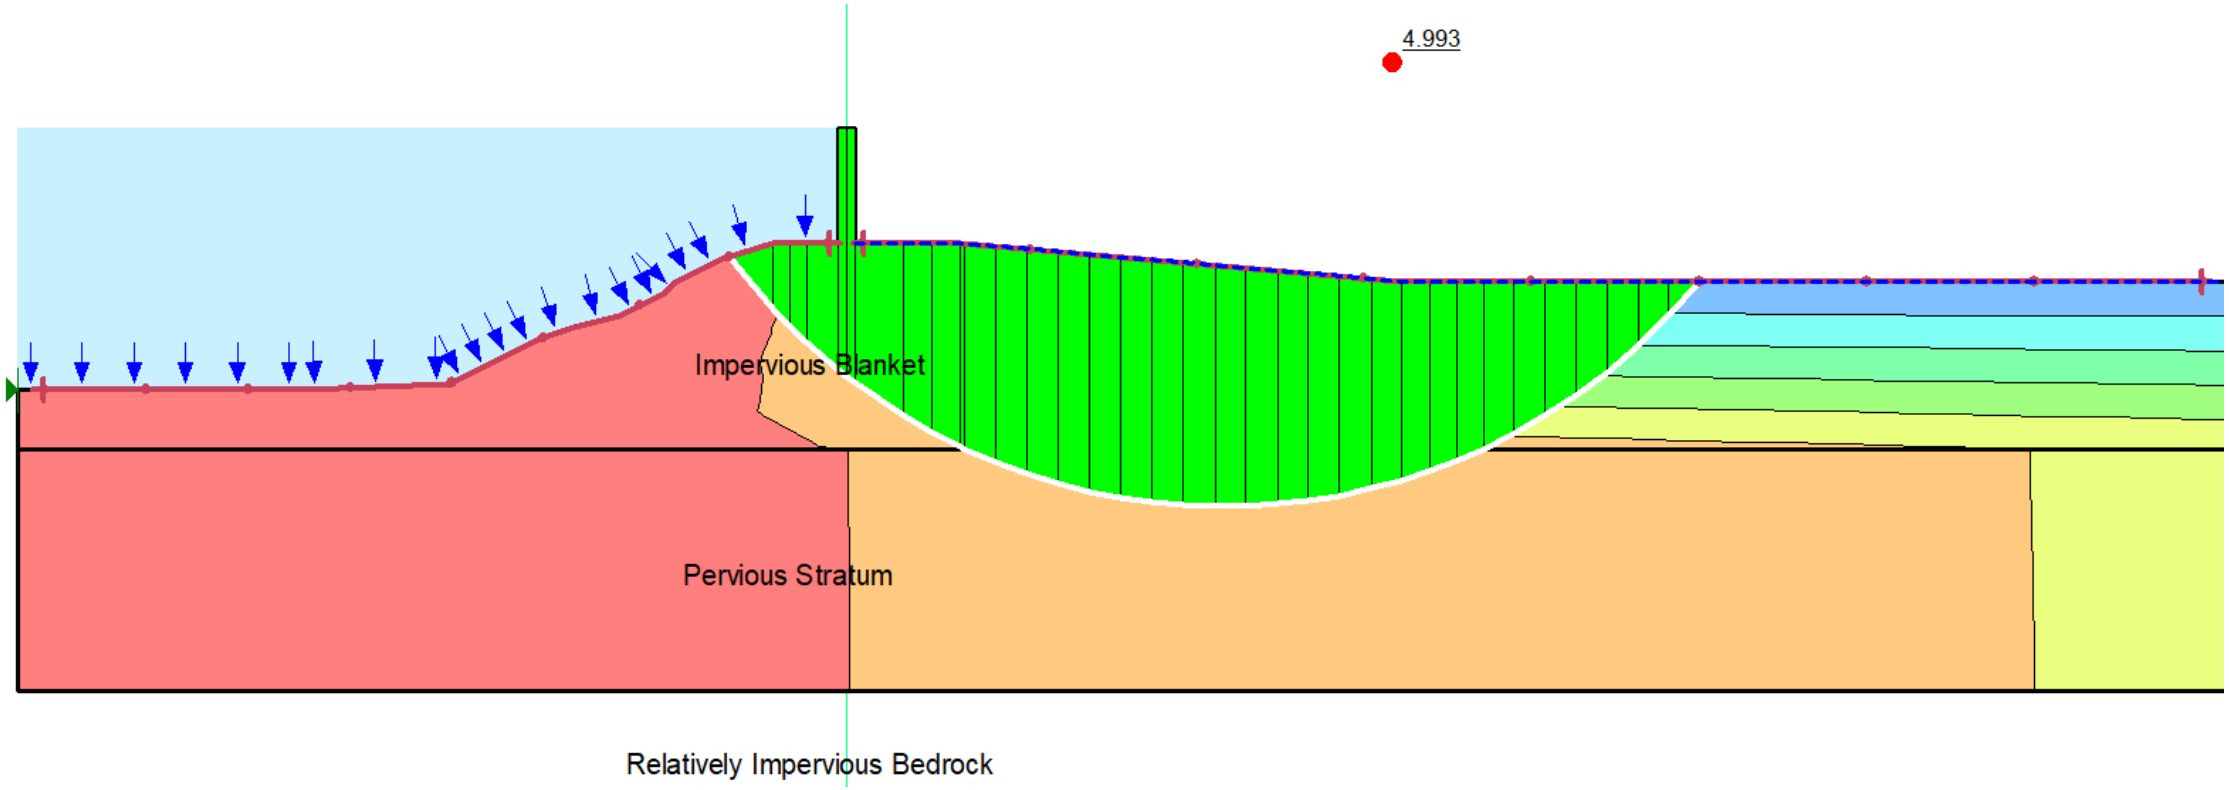


RB F 33+80/UTC 41+75

SLOPE/W End of Construction Results

Analyzed with a landside slope rather than the existing flat landward surface in order to find a feasible slope failure surface

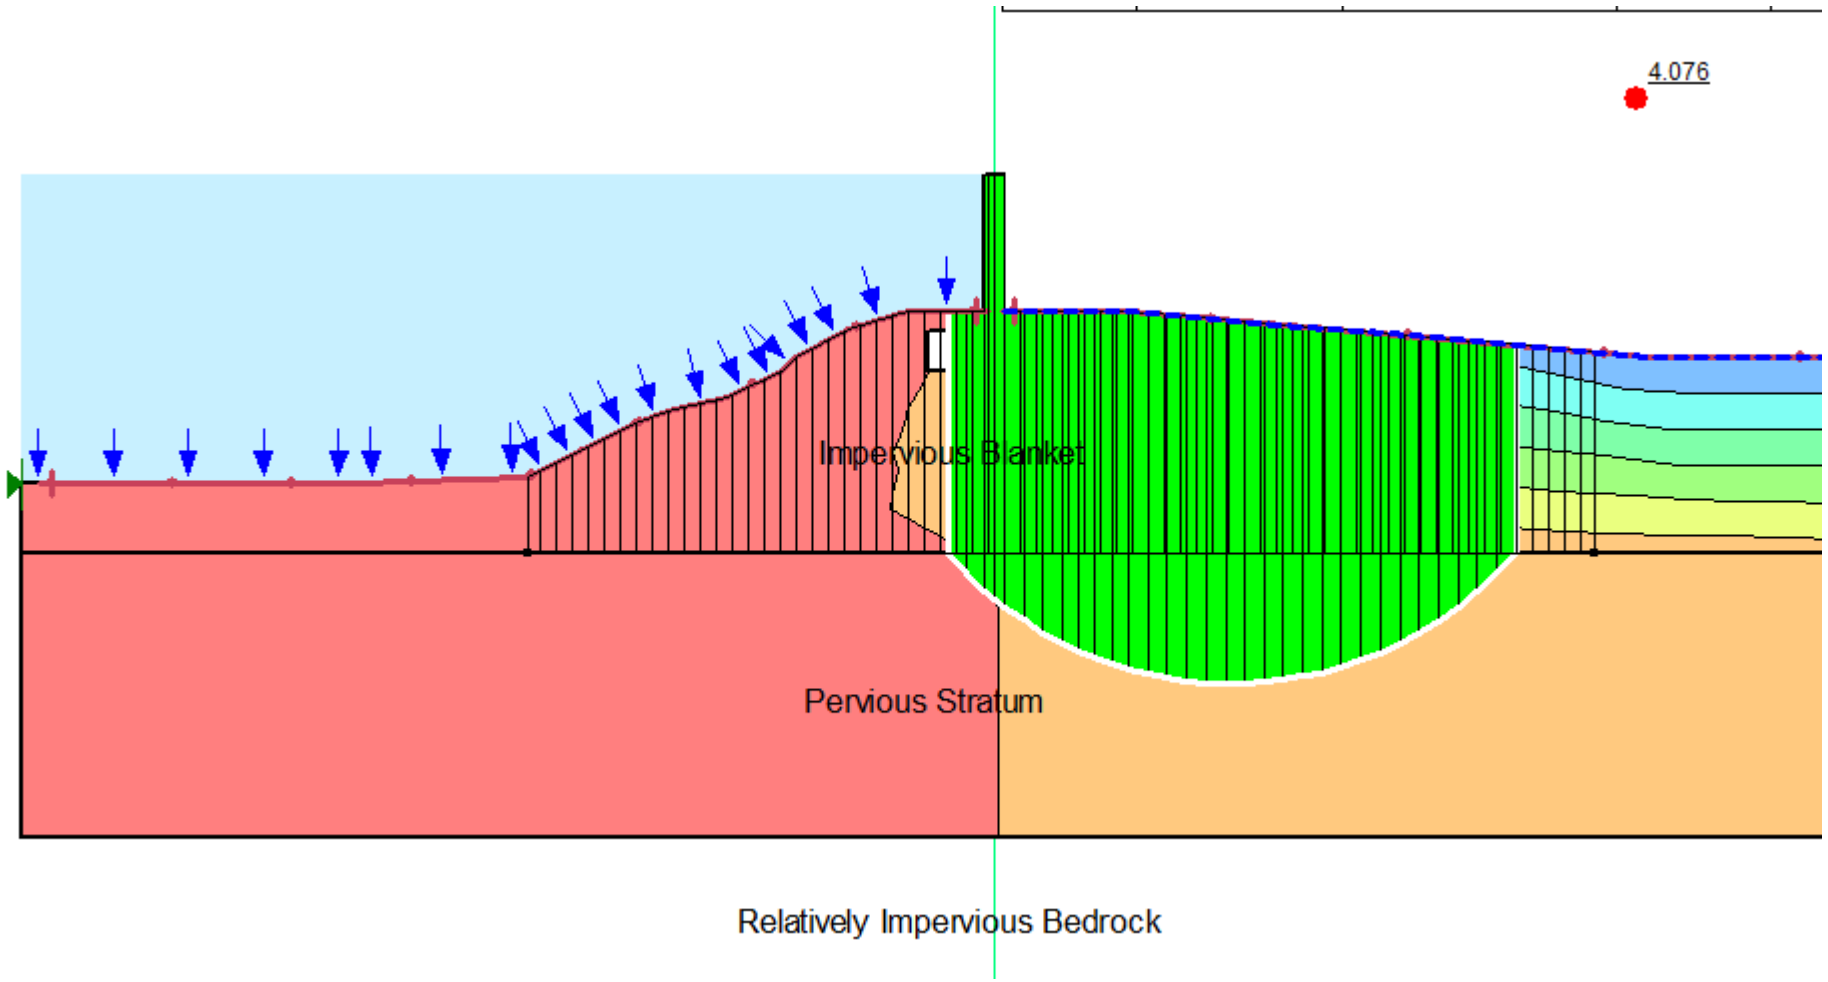
With this more conservative slope, FS is still greater than 1.3 required



RB F 33+80/UTC 41+75 SLOPE/W End of Construction w Tension Crack Results

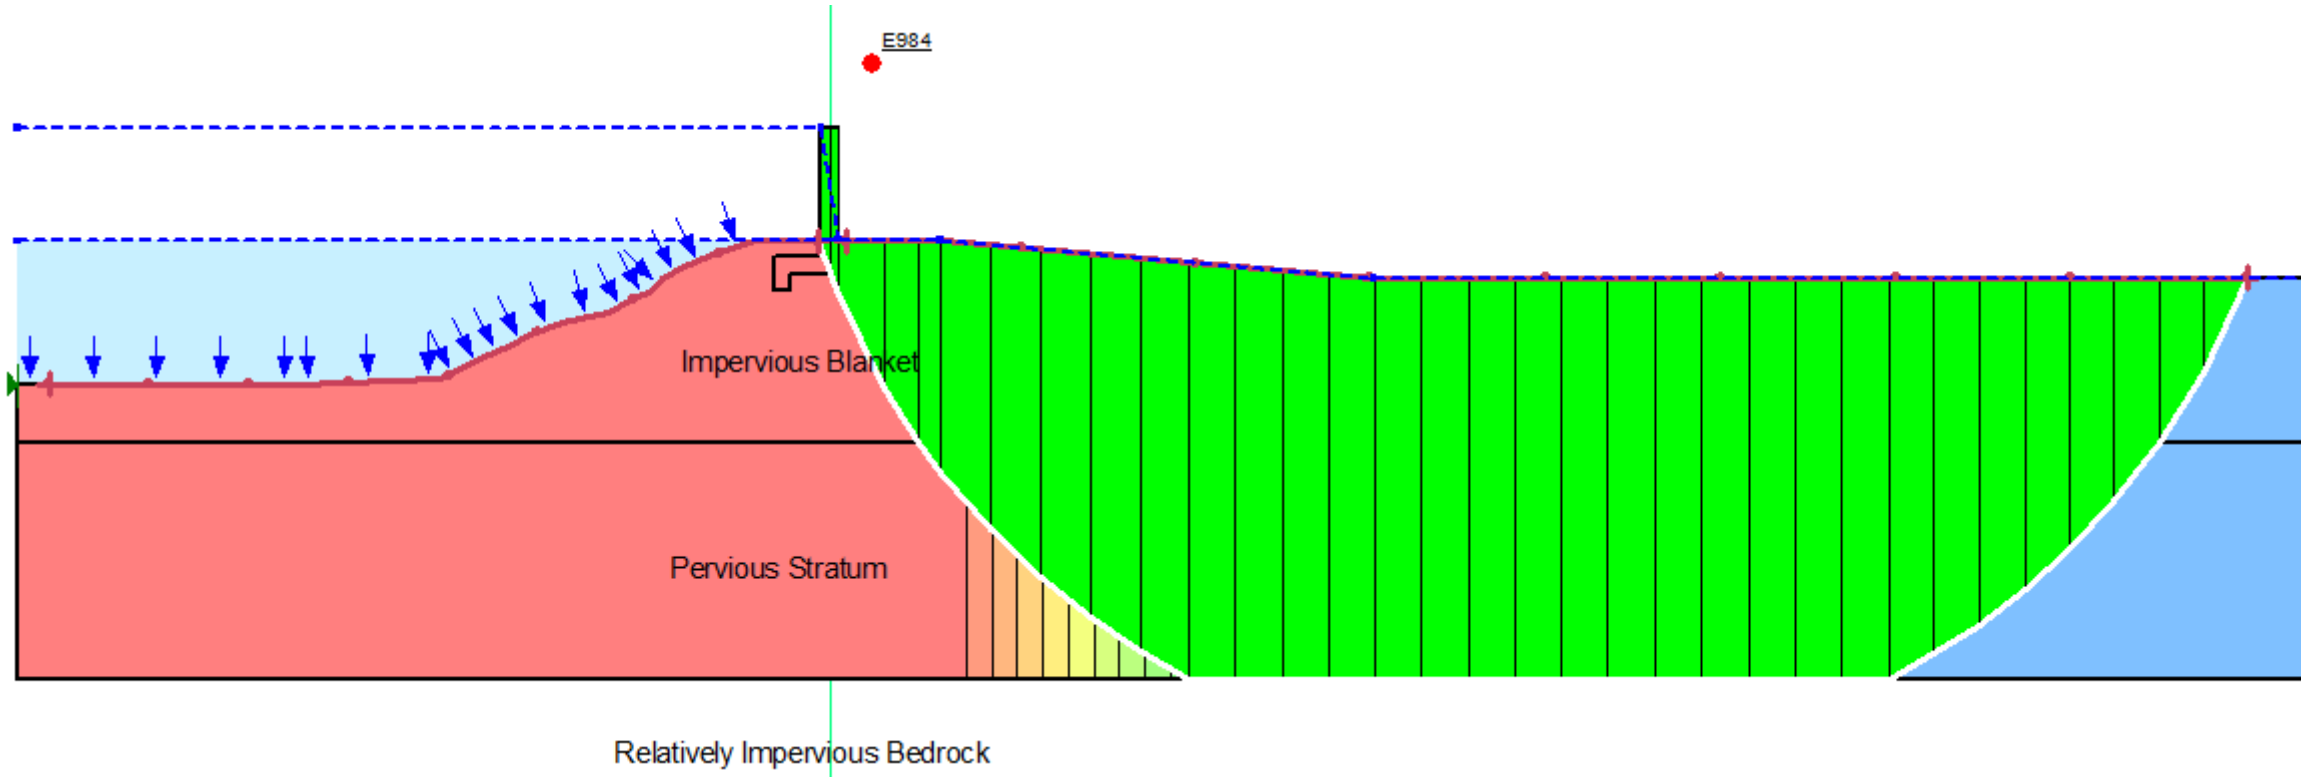
Analyzed with a landside slope rather than the existing flat landward surface in order to find a feasible slope failure surface

With this more conservative slope, FS is still greater than 1.3 required



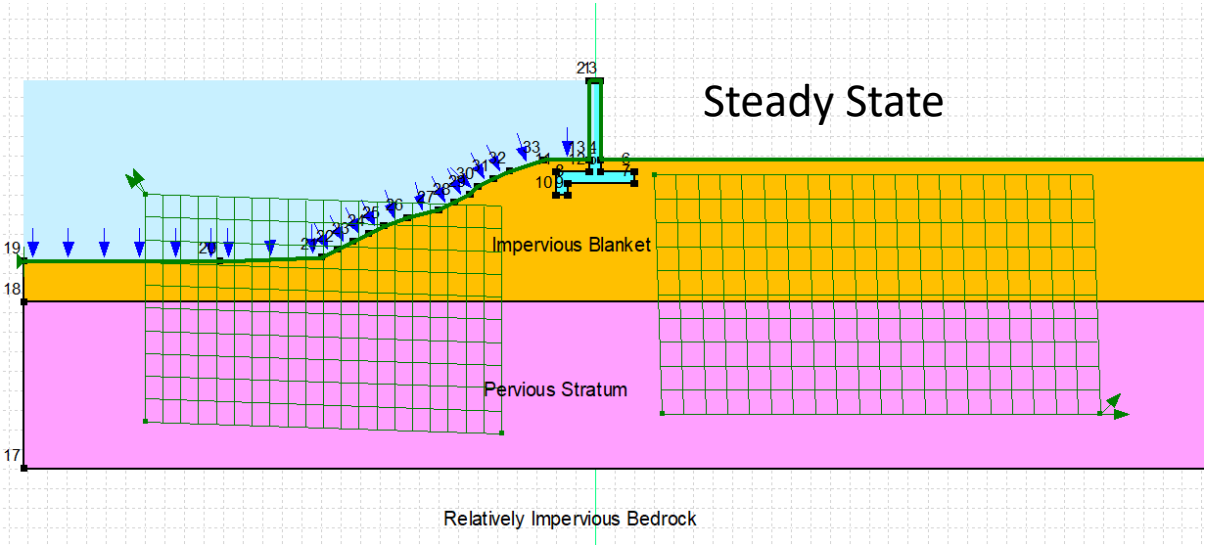
RB F 33+80/UTC 41+75 SLOPE/W Rapid Drawdown Results

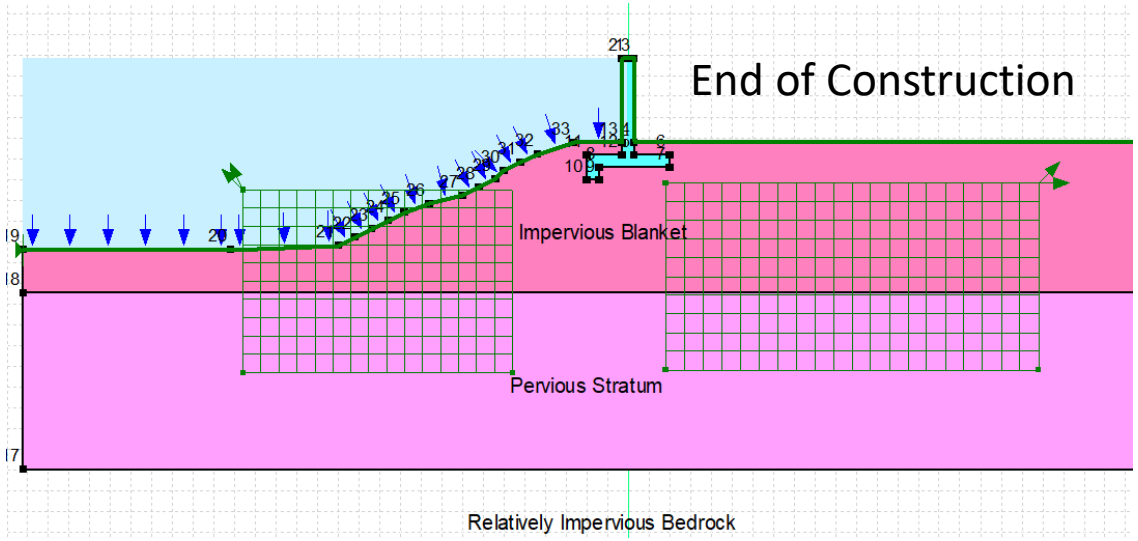
The landside slope added to evaluate steady state and end of construction did not affect rapid drawdown with its failure on the riverside slope

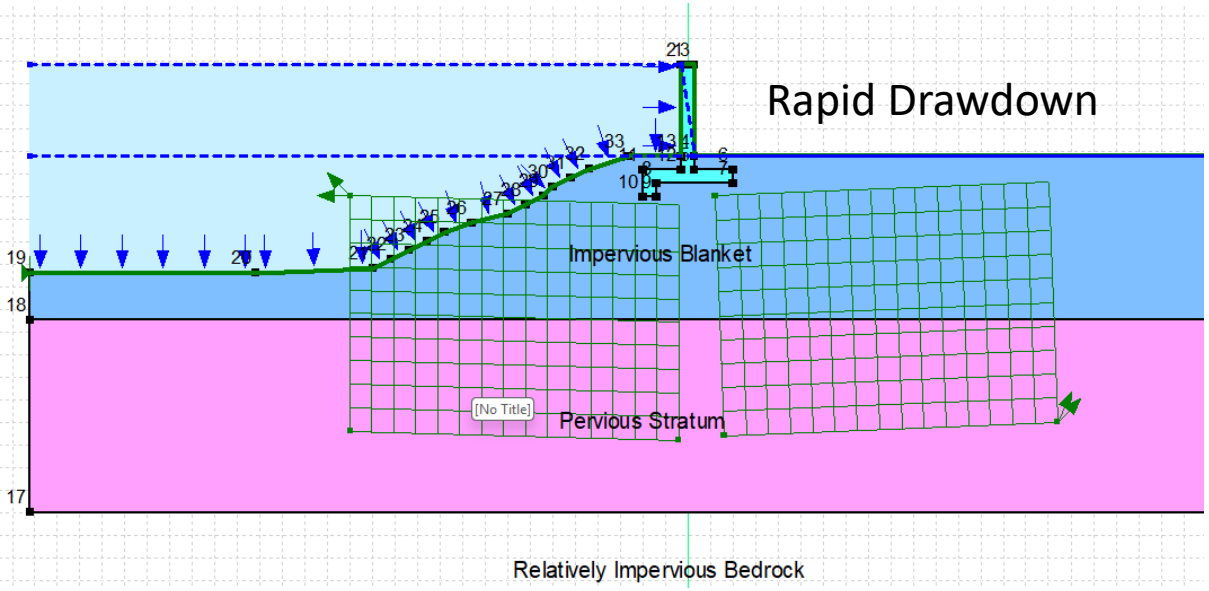


RB F 33+80/UTC 41+75 SLOPE/W Block Failure Inputs

Also tried stability runs with block-specified failure surface. Only rapid drawdown analyses ran without an error message.





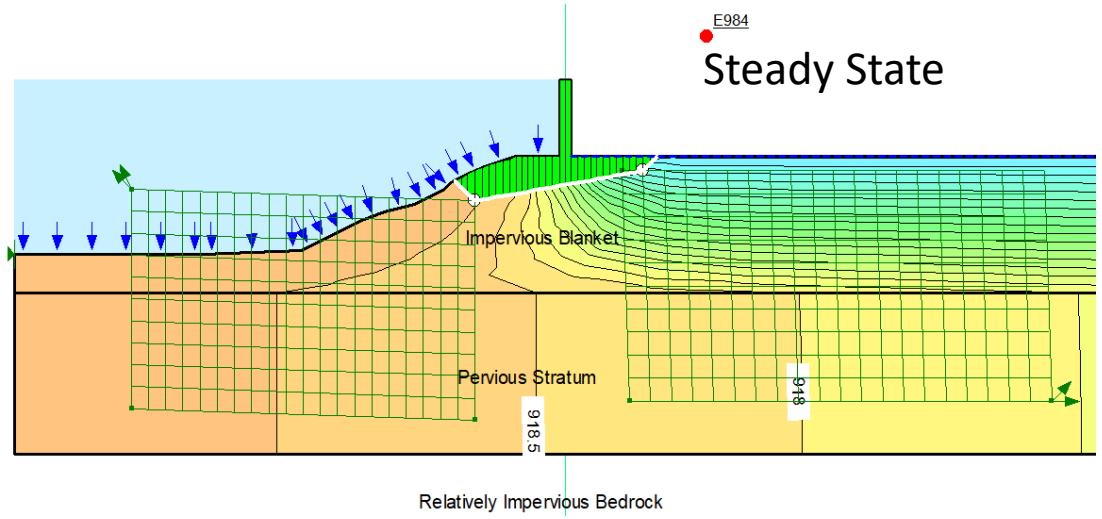


RB F 33+80/UTC 41+75

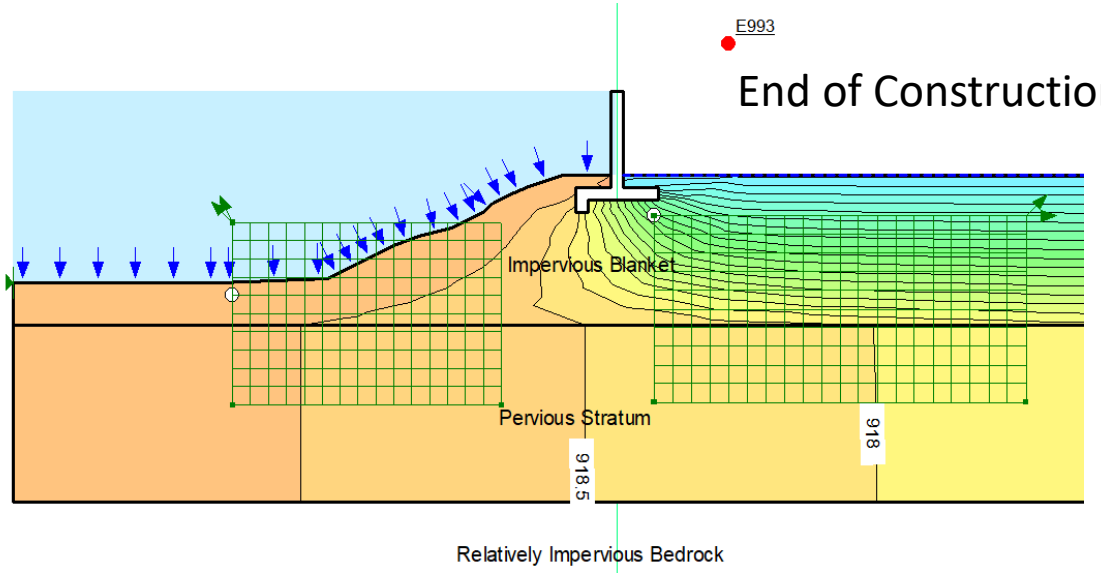
SLOPE/W Block Failure Output

Also tried stability runs with block-specified failure surface. Tried several different variations with similar results. Only rapid drawdown analyses ran without an error message.

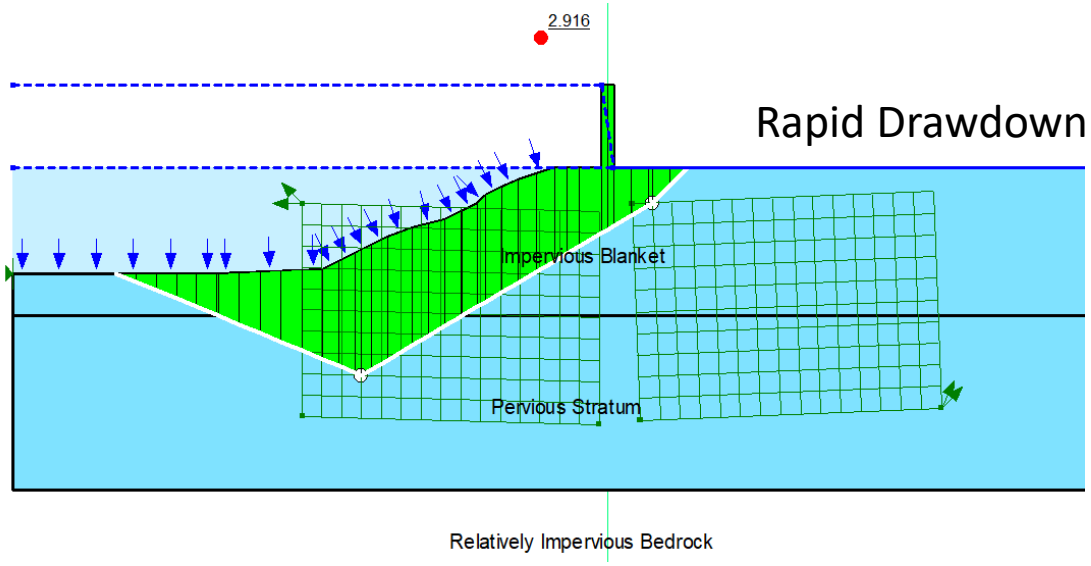
Steady State



End of Construction



Rapid Drawdown



Error 993: Slip surface is shallower than defined minimum depth

Error 984: Slip surface intersects vertical/overhanging bedrock or weak surface, contains air gap, bedrock, or weak surface

For steady state, the same error messages were obtained for runs at reduce slopes. Based on high FS or error messages and lack of sensitivity to the slope on other runs, additional runs at reduced slopes were not attempted at this time for end of construction or drawdown

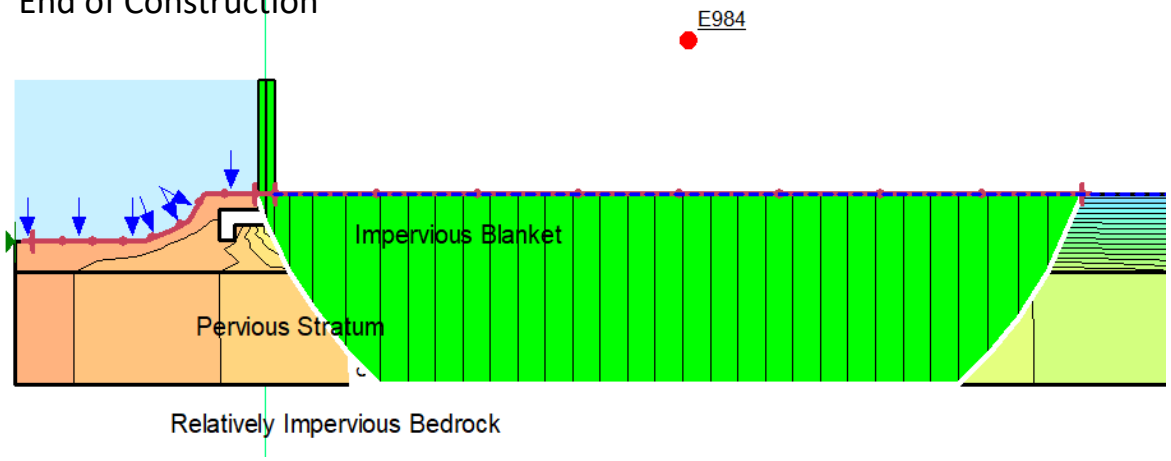
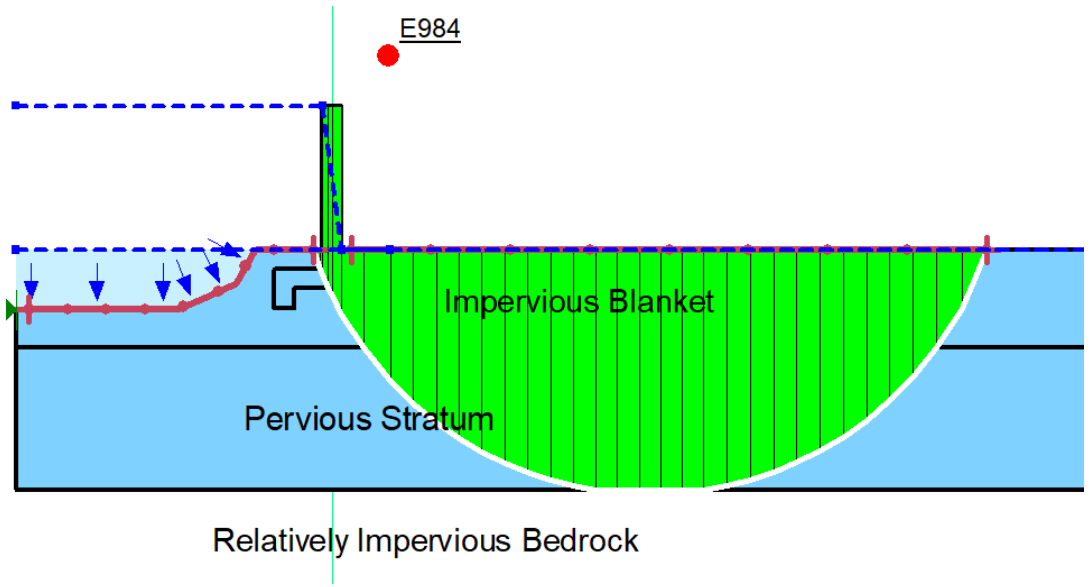
LB R1 F 13+20/UTC 0+50 SLOPE/W Results

Like with the other floodwall, the analyses resulted in errors due to the failure surface intersecting shallow bedrock

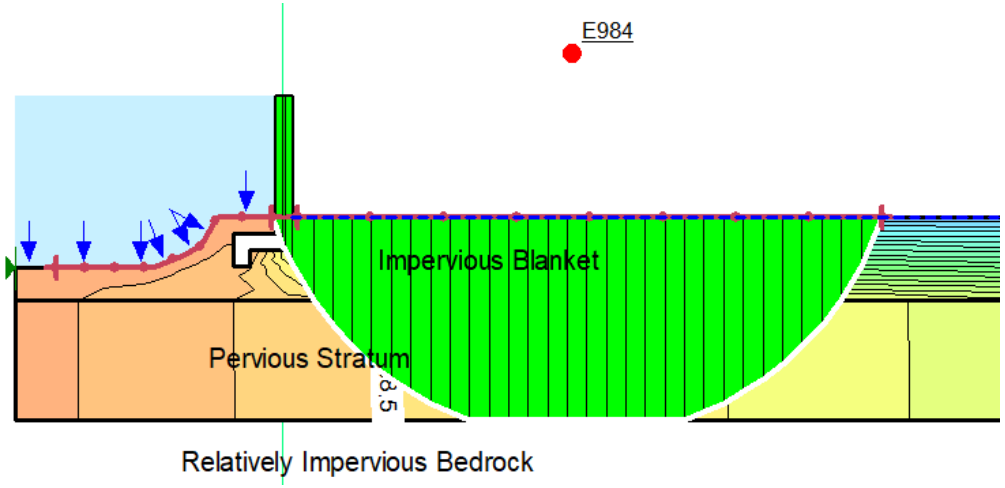
End of Construction



Rapid Drawdown



Steady State



For this cross section with very shallow bedrock, adding a landside slope did not help find a feasible failure surface

The end of construction with tension crack case did obtain a factor of safety (see next page)

For steady state, the same error messages were obtained for runs at reduced slopes. Based on high FS or error messages and lack of sensitivity to the slope on other runs, additional runs at reduced slopes were not attempted at this time for end of construction or drawdown

LB R1 F 13+20/UTC 0+50 SLOPE/W Results

Factor of Safety was obtained from end of construction with tension crack case

End of Construction w Tension Crack

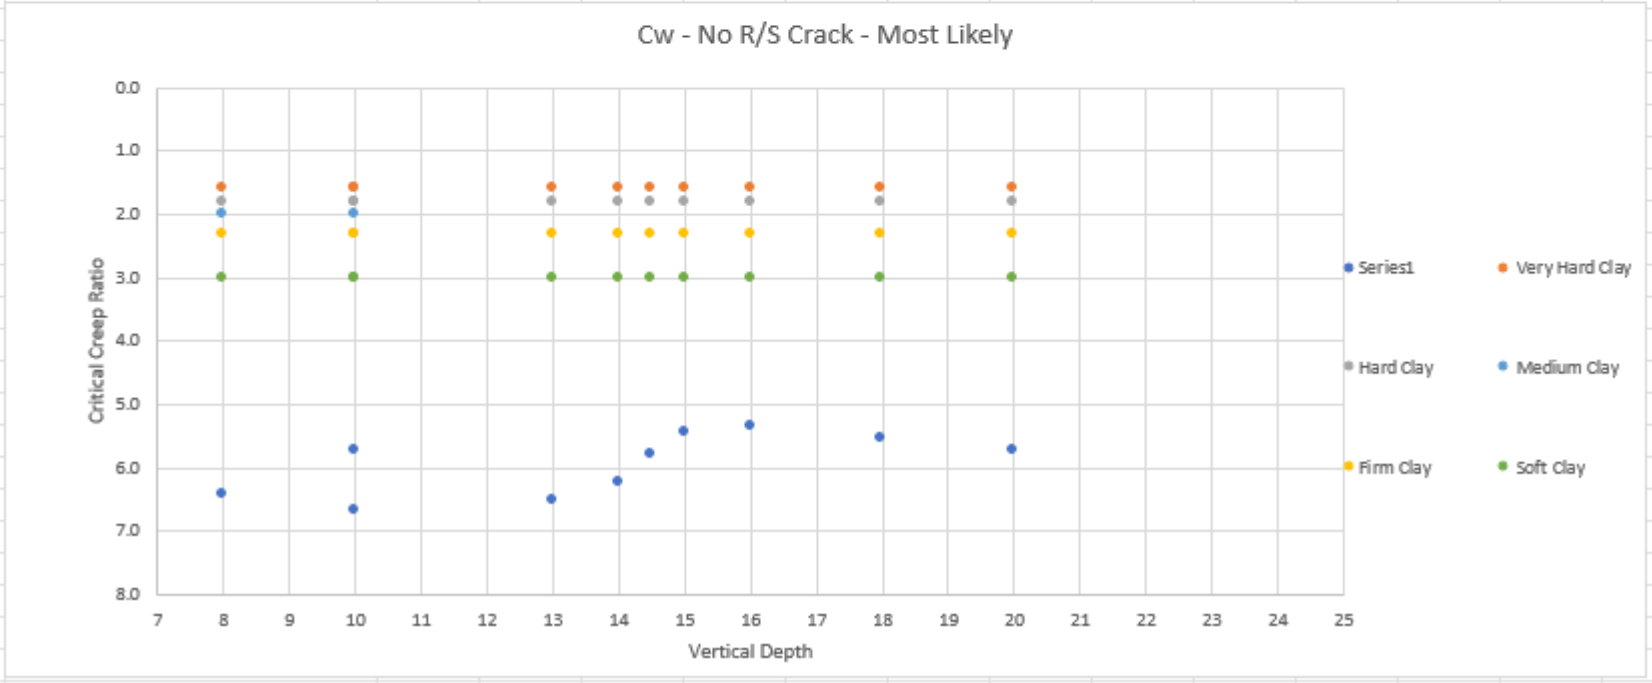
I-wall Line of Creep Analysis

No Crack vs. Vertical Crack

Using Lane's Theory

L_V for no crack scenario equals 2 x sheet pile depth (seepage has to travel full distance down and up the sheet pile)

Lane's Weighted Creep Ratio (No Crack)												
Dimension	Unit	A	B	C	D	E	F	G	H	I	J	K
Thickness of sheet pile	Feet	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125
Depth of sheet pile	Feet	6	8	10	10	13	14	14.5	15	16	18	20
Concrete - Beyond Sheet Pile Side	Feet	0	0	0	0	0	0	0	0	0	0	0
Concrete - Below Sheet Pile	feet	0	0	0	0	0	0	0	0	0	0	0
Horizontal Length	L	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125
Vertical Depth (penetration depth from CWALSHT analysis)	Feet	6	8	10	10	13	14	14.5	15	16	18	20
Head (I-wall height)	Feet	2	2.5	3	3.5	4	4.5	5	5.5	6	6.5	7
Cw	H/L	6.0	6.4	6.7	5.7	6.5	6.2	5.8	5.5	5.3	5.5	5.7
Critical Creep Ratios												
Very Hard Clay		1.6	1.6	1.6	1.6	1.6	1.6	1.6	1.6	1.6	1.6	1.6
Hard Clay		1.8	1.8	1.8	1.8	1.8	1.8	1.8	1.8	1.8	1.8	1.8
Medium Clay		2	2	2	2	2	2	2	2	2	2	2
Firm Clay		2.3	2.3	2.3	2.3	2.3	2.3	2.3	2.3	2.3	2.3	2.3
Soft Clay		3	3	3	3	3	3	3	3	3	3	3



4.16

Lane's theory resolves itself into the following equation:

$$C_w = \frac{\Sigma L_H + 3\Sigma L_V}{3H} \qquad 4.7$$

where C_w = weighted creep ratio
L_H = horizontal or flat contact distances
L_V = vertical or steep contact distances
H = head between headwater and tailwater

Material	C_w
Clean gravel	5.0
Clean sand or sand and gravel mixture	6.5
Very fine sands and silts	8.5
Well-graded mixture of sand, silt, and less than 15 percent clay	5.5
Well-graded mixture of sand, silt, and more than 15 percent clay	4.0
Firm clay	2.3
Hard clay	1.8

TABLE 4.3

Material	C_w
Very fine sand and silt	8.5
Fine sand	7.0
Medium sand	6.0
Course sand	5.0
Fine gravel	4.0
Medium gravel	3.5
Course gravel including cobbles	3.0
Boulders with some cobbles and gravel	2.5
Soft clay	3.0
Medium clay	2.0
Hard clay	1.8
Very hard clay or hardpan	1.6

Sheet pile depths required for rotational stability will satisfy creep ratio requirements

L_V for crack scenario equals 1 x sheet pile depth (seepage has half the travel distance due to the crack)

Lane's Weighted Creep Ratio (With a Crack)												
Dimension	Unit	A	B	C	D	E	F	G	H	I	J	K
Thickness of sheet pile	Feet	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125	0.03125
Depth of sheet pile	Feet	6	7	8	10	13	14	14.5	15	16	18	20
Concrete - Beyond Sheet Pile Side	Feet	0	0	0	0	0	0	0	0	0	0	0
Concrete - Below Sheet Pile	feet	0	0	0	0	0	0	0	0	0	0	0

4.16

Lane's theory resolves itself into the following equation:

$$C_w = \frac{\Sigma L_H + 3\Sigma L_V}{3H} \qquad 4.7$$

where C_w = weighted creep ratio
L_H = horizontal or flat contact distances
L_V = vertical or steep contact distances
H = head between headwater and tailwater

Material	C_w
Clean gravel	5.0
Clean sand or sand and gravel mixture	6.5
Very fine sands and silts	8.5
Well-graded mixture of sand, silt, and less than 15 percent clay	5.5
Well-graded mixture of sand, silt, and more than 15 percent clay	4.0
Firm clay	2.3
Hard clay	1.8

TABLE 4.3

Material	C_w
Very fine sand and silt	8.5
Fine sand	7.0
Medium sand	6.0
Course sand	5.0
Fine gravel	4.0
Medium gravel	3.5
Course gravel including cobbles	3.0
Boulders with some cobbles and gravel	2.5
Soft clay	3.0
Medium clay	2.0
Hard clay	1.8
Very hard clay or hardpan	1.6

Sheet pile depths required for rotational stability will satisfy creep ratio requirements

APPENDIX B.4 – FLOODWALL BEARING CAPACITY

Bearing Capacity

Bearing capacity for floodwall footings was determined for drained and undrained cases, using a friction angle of 28 degrees for the drained case (see 6.9.2) and a cohesion of 1000 psf for the undrained case (see 6.9.3). A groundwater depth of 10.8 feet was used (see 6.3 and this appendix).

Floodwall continuous footing widths ranged from 7 feet to 20 feet and depth is 3 feet below adjacent finished grade (see this appendix). For bearing capacity, for drained conditions, the smallest footing size results in smallest bearing capacity for Terzaghi and Vesic methods. For bearing capacity, for undrained conditions, Terazaghi method result does not change with footing size and Vesic bearing capacity goes down as footing size increases. Showed footing widths of 7 feet for drained and 20 feet for undrained.

The undrained case controlled. An allowable bearing capacity of 2000 psf was selected for design.

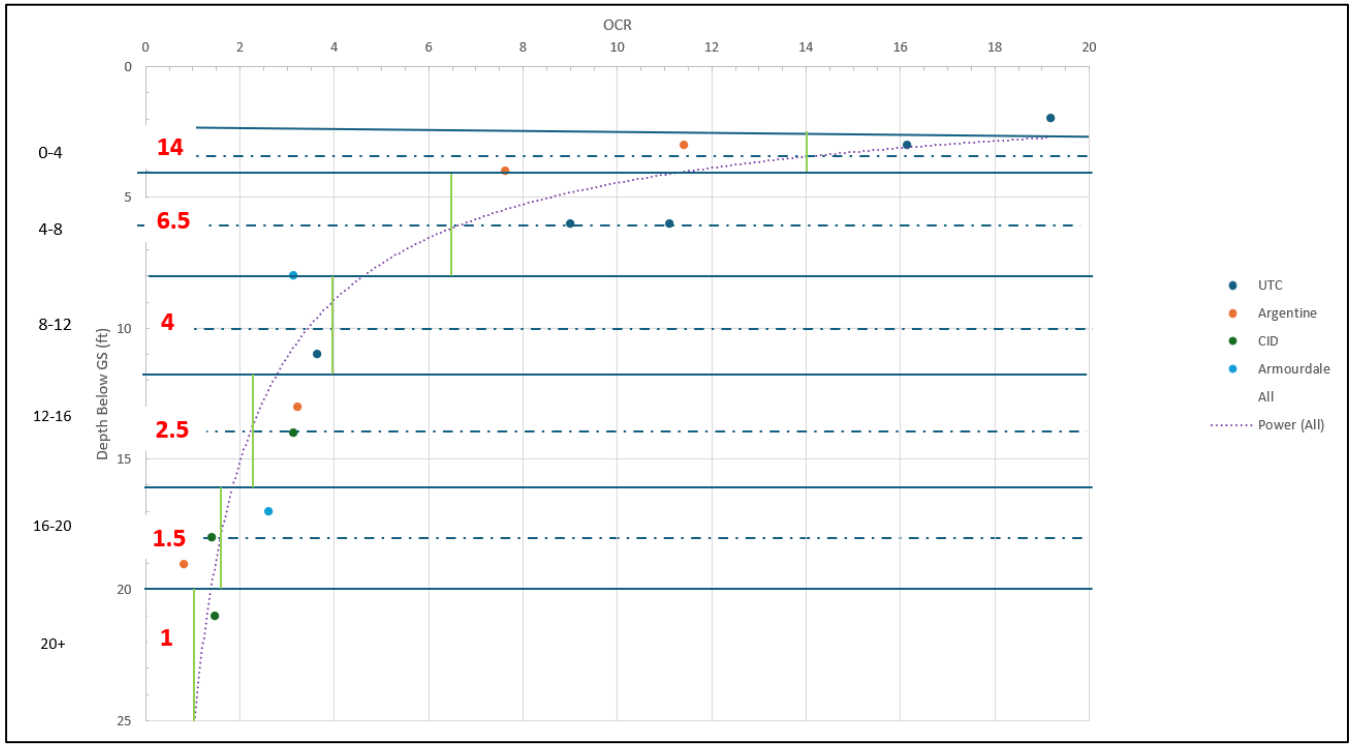
Overconsolidation Ratio (OCR) = Preconsolidation Pressure/Overburden Pressure

Overconsolidation Margin = Preconsolidation Pressure – Overburden Pressure

An overconsolidation margin of 4500 psf was used in the Coduto spreadsheet.



The design overconsolidation ratio was varied by depth incorporating the consolidation testing results from UTC and similar soils at KC Levees with a power trendline

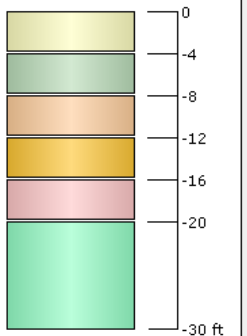
Soil Layer Column



Insert Layer Above | Insert Layer Below | Delete Layer | OK | Cancel

Layer 6 only used for the 12’ wall in an area with 30’ of compressible soil above bedrock. In other areas, bedrock was found at 20’.

Assumed no groundwater/groundwater at creek/bedrock elevation. According to Settle3 documentation, groundwater is not needed for calculations that are not time-dependent.

- If you are NOT modelling time-dependent consolidation, then you do not necessarily have to define groundwater (e.g. if you are only interested in immediate settlement or long-term consolidation).

https://www.rocscience.com/help/settle3/documentation/project-settings/groundwater

Bedrock Depth

The majority of the borings showed compressible clay soil down to bedrock. Some borings had clayey gravel or weathered rock above bedrock. Bedrock depth varied from 6.5’ to 27.8’ below grade, generally deeper on the downstream (north) end of the project.

Boring	Bedrock Depth (ft)	Bedrock EL

PLUS STD DEV	19.7	
MINUS STD DEV		890.5

The area around ADUC-196 (UTC RB 60+70) has a floodwall planned, 9.5’ max above grade (12’ total stem length).

Settlement Checks

- The area around ADUC-196 (UTC RB 60+70) has a floodwall planned, 9.5’ max above grade.
- Checked settlement for 9.5’ floodwall with 30’ of compressible fill
- Checked other floodwall and levee settlements with 20’ of compressible fill

Levee Settlement

The maximum levee settlement (for 10’ tall levee with 20’ of compressible overburden soils) is expected to be around 3 inches

1V:3H slopes for 10’ tall levee = 30’ slope on each side
30’(2) + 10’ crest width = 70’ base width

$\tan^{-1}$ (1/3) = 18.4 degrees

NC: Normally Consolidated

$$S_c = C_c H_c/(1+e_o) \log ((p_o + \Delta p)/p_o)$$

uses virgin compression curve

OC1: Overconsolidated but not loaded beyond Preconsolidation Pressure

$$S_c = C_s H_c/(1+e_o) \log ((p_o + \Delta p)/p_o)$$

uses recompression curve

OC2: Overconsolidated and loaded beyond Preconsolidation Pressure

$$S_c = C_s H_c/(1+e_o) \log p_c/p_o + C_c H_c/(1+e_o) \log ((p_o + \Delta p)/p_o)$$

uses both curves

Definitions

P_c	Max past pressure based on overburden*OCR
P_o'	Effective Overburden Pressure, γ x z
ΔP	Stress Increase from Fill or Footing Pressure
P_f	Final Pressure at given depth, P_o' + Δp
εrz	Recompressive Strain
εcz	Compressive Strain
C_r	Recompression Index
C_c	Virgin Compression Index
H_o	Sublayer Thickness
e_o	Initial Void Ratio

Preconsolidation Margin

$P_m' = P_c - P_o'$

P_o' for sample at depth of sample

for Normally Consolidated, $P_m' = 0$

Adjusted Preconsolidation Pressure

P_c adjusted = $P_m' + P_o'$ at depth being analyzed

Floodwall Settlement

The maximum floodwall settlement (for 12’ tall wall [10.5’ above grade] with 30’ of compressible overburden soils) is expected to be 0.93 inches

Max total allowable settlement is 1” based on waterstops and structural considerations

For the 8’ tall wall [6.5’ above grade]: 1.3 yd^3 of concrete
based on EDD-S spreadsheet on 1/8/26
Concrete volume = 1.3*27 = 35.1 ft^3
Concrete weight = 35.1ft^3*150 pcf = 5265 lb/ft wall length
Check w 20’ compressible soil

For the 12’ tall wall [10.5’ above grade]: 2.22 yd^3 of concrete
based on EDD-S spreadsheet on 1/8/26
Concrete volume = 2.22*27 = 59.94 ft^3
Concrete weight = 59.94ft^3*150 pcf = 8991 lb/ft wall length
Check with 30’ compressible soil

For the 14’ tall wall [12.5’ above grade]: 2.51 yd^3 of concrete
based on EDD-S spreadsheet on 1/8/26
Concrete volume = 2.51*27 = 67.77 ft^3
Concrete weight = 67.77ft^3*150 pcf = 10,165.5 lb/ft wall length
Check with 20’ compressible soil

APPENDIX B.6 – RIPRAP AND BEDDING DESIGN

UTC Riprap Design

D100 max riprap sizes needed for UTC channel velocities were provided by H&H/Civil for various locations in the system using FS of 1.5, with results of 42”, 33”, and 21”

The 42” riprap was needed for one reach downstream of Merriam Bridge (right bank UTC Sta 64+00 to 65+75).
As 42” riprap is not locally available, rather than import rock from a nonlocal source, H&H determined it was okay to use a reduced FS of 1.3 for this area (1.1 is the minimum required), resulting in a D100 of 36”

From Chapter 4 of DDR:

A total of six unique maximum riprap diameters were determined from the HEC-RAS tool and then condensed down to three to reduce design complexity. The largest riprap required has a D_{100} of 42 inches. This is located downstream of the Merriam Drive bridge on the right bank which is a sharp outside bend. A 36-inch diameter was selected for this area due to the lack of local availability of 42-inch riprap.

A D_{100} of 36 inches was deemed suitable as it retained a factor of safety of 1.3 which is still above the minimum factor of safety (1.1) specified in EM 1110-2-1601. Additionally, this section of the flood protection system is lower risk given the riprap is located at the downstream end of the project. Any floodwall failure at this location would result in backwater flooding which would act as a bathtub until river stages drop and water drains out of the interior through the breach. The bathub effect occurs when backwater enters the downstream portion of a protection system and slowly fills rather than conveying through the leveed area. This presents less life safety risk than breaches that occur upstream and have hydraulic head to flow through the leveed area.

UTC Riprap Design

Notes:
1. Stone weight limit data from ETL 1110-2-120 (HQUSACE, 1971 (14 May), "Additional Guidance for Riprap Channel Protection, Ch 1," US Government Printing Office, Washington, DC). Relationship between diameter and weight is based on the shape of a sphere.
2. The maximum limits at the W_{50} and W_{15} sizes can be increased as in the Lower Mississippi Valley Division Standardized Gradations shown in Appendix F.

Table 3-1 in EM 1110-2-1601 (Hydraulic Design of Flood Channels) was used to develop a range of weights for W100, W50, and W15 for the different specific weight options. EDG-G stated that the 155 and 165 pcf specific weights should be used for rock in this area.

- For 36” riprap, W100 of 877-2331 lb, W50 of 438-691 lb, and W15 of 137-346 lb
- For 33” riprap, W100 of 675-1797 lb, W50 of 338-532 lb, and W15 of 105-266 lb
- For 21” riprap, W100 of 174-463 lb, W50 of 87-137 lb, and W15 of 27-69 lb

UTC Riprap Design

Layer Thickness

EM 1110-2-1601
Change 1
30 Jun 94

Section 3-2e:

e. Layer thickness. All stones should be contained within the riprap layer thickness to provide maximum resistance against erosive forces. Oversize stones, even in isolated spots, may result in riprap failure by precluding mutual support and interlock between individual stones, causing large voids that expose filter and bedding materials, and creating excessive local turbulence that removes smaller size stone. Small amounts of oversize stone should be removed individually and replaced with proper size stones. The following criteria apply to the riprap layer thickness:

(1) It should not be less than the spherical diameter of the upper limit W_{100} stone or less than 1.5 times the spherical diameter of the upper limit W_{50} stone, whichever results in the greater thickness.

(2) The thickness determined by (1) above should be increased by 50 percent when the riprap is placed underwater to provide for uncertainties associated with this type of placement. At one location in the US Army Engineer Division, Missouri River, divers and sonic sounders were used to reduce the underwater thickness to 1.25 times the dry placement thickness.

Layer thickness should not be less than spherical diameter of the upper limit W100 stone

36” for 36” D100 riprap

Layer thickness should not be less than 1.5 times the spherical diameter of the upper limit W50 stone

Largest W50 would be 691 lb
691lb/165pcf = 4.19 ft^3
$4/3\pi r^3 = 4.19\ ft^3$, r = 1 ft, d = 2 ft
1.5 x 24” = 36”

Layer thickness for 36” riprap should be at least 36”

UTC Bedding Design

No specific guidance is available for levees. General requirements for dams were used.

The gradation of the bedding material should provide for retention of bedding particles by the overlying riprap layer and for retention of the material underlying the bedding layer. Bedding material should generally conform to Equations C-1 through C-3 from EM 1110-2-2300, General Design and Construction Considerations for Earth and Rock-Fill Dams (2004).

In addition, the bedding must not be so broadly graded as to be susceptible to internal instability. USBR guidance recommends bedding material be considered internally unstable when its coefficient of uniformity is less than 10 (Design Standards No. 13 Embankment Dams, Chapter 7 Riprap Slope Protection, Section 7.3.7.1, dated May 2014).

EM 1110-2-2300 states that bedding materials over erosion-resistant clay materials need not be designed to meet the criteria of Equation C-1 or C-2 but must still satisfy Equation C-3.

$$D_{15B} > 5D_{15E} \quad \text{(C-1)}$$

$$D_{15B} < 5D_{85E} \quad \text{(C-2)}$$

$$D_{85B} > D_{15R}/5 \quad \text{(C-3)}$$

where

D_{15B} = the 15 percent passing the size of the bedding

D_{85B} = the 85 percent passing the size of the bedding

D_{15E} = the 15 percent passing the size of the material to be protected

D_{85E} = the 85 percent passing the size of the material to be protected

D_{15R} = the 15 percent passing the size of the riprap

An intermediate filter layer may be required between the bedding and riprap to prevent washout of the bedding. Bedding layers over erosion-resistant clay materials need not be designed to meet the criteria of Equation C-1 or Equation C-2 but must still satisfy Equation C-3. Each design should produce a specification that defines material sources, gradations, and layer thickness to economically provide the riprap and bedding layers required to protect the embankment.

UTC Bedding Design

Riprap will be placed over impervious fill on the riverside levee slope. Levee construction specifications define impervious fill as lean clay, low plasticity silt, or borderline clay and silt in accordance with ASTM D2487.

The in-place soils at Upper Turkey Creek are predominantly lean clays, so the existing bank slope and embankment fill material obtained from required excavations will likely be lean clay. Borrow soils are expected to be lean clay soils. The levee cross section is shown as homogenous impervious fill in plans.

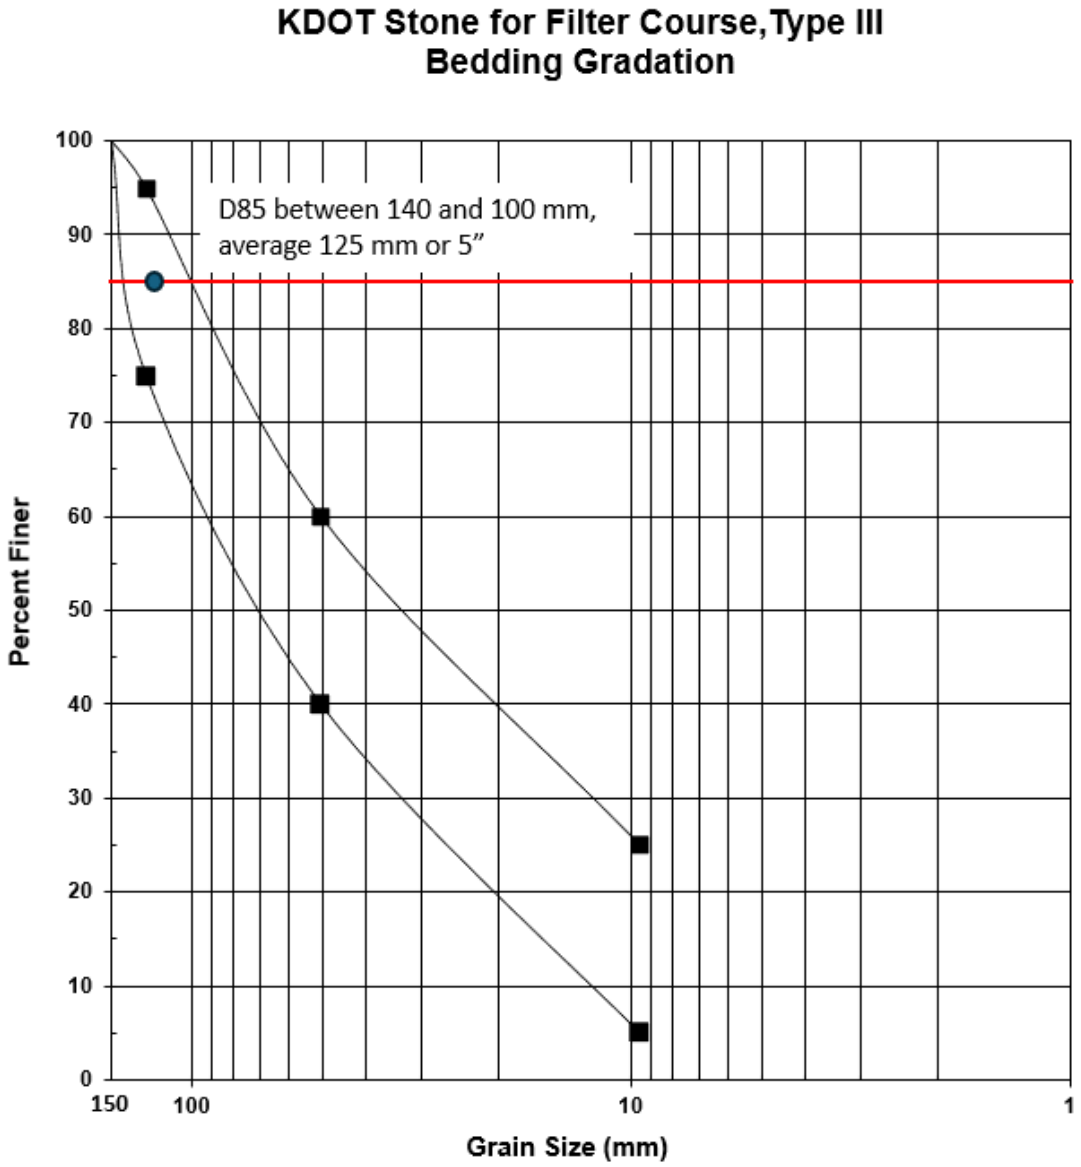
As the riverside levee slope will consist of erosion-resistant clay materials, bedding is being designed to satisfy Equation C-3 but not C-1 and C-2. Retention of the material underlying bedding is less important for levees which are loaded irregularly for short durations as compared to dams.

It is recommended that bedding material for the riprap overlay meet the gradation requirements of Kansas Department of Transportation (KDOT) Stone for Filter Course, Type III material.

TABLE 1114-3: STONE FOR FILTER COURSE									
Material	Percent Retained on Sieve Size								
	6”	5”	4”	3”	2”	1”	½”	3/8”	No. 4
Type I		0	0-5		10-40	25-60		55-85	70-95
Type II			0	0-5			50-90		
Type III	0	5-25			40-60			75-95	

Sieve/Size	Percent Finer
6” (152.4 mm)	100
5” (125 mm)	75-95
2” (50.8 mm)	40-60
3/8” (9.525 mm)	5-25

UTC Bedding Design



UTC Bedding Design

Retention of Bedding Material by Riprap per Equation C-3

$$D_{85B} > D_{15R}/5$$

Determined D_{15R} for the largest 36" riprap using the largest W_{15R} for the 165 pcf specific weight. The results are the same using the largest W_{15R} with the 155 pcf specific weight.

For the 36" riprap, the largest W_{15} for that range is 346 lb. 346 lb/165 pcf = 2.10 ft^3 volume. Using volume of sphere of $4/3\pi r^3$, r = 0.794 ft and d = 1.58 ft or 19.06".

$D_{15R}/5$ = 19.06"/5= 3.81"
D_{85B} ~ 5" supposed to be >$D_{15R}/5$ ~ 3.81"
For the largest riprap, Equation C-3 is satisfied

The average W_{15} for 36" riprap is 246 lb. 246 lb/165 pcf = 1.49 ft^3 volume. Using volume of sphere of $4/3\pi r^3$, r = 0.709 ft and d = 1.42 ft or 17.01".

$D_{15R}/5$ = 17.01"/5= 3.40"
D_{85B} ~ 5" >D_{15R} ~ 3.4"
For the average size 36" riprap, Equation C-3 is satisfied

For the smaller 33" and 21" riprap used over the majority of the project, the D_{15R} is smaller than for the 36" riprap and Equation C-3 is satisfied.

Internal Stability of Bedding

The approximate coefficient of uniformity C_u for the recommended bedding gradation D_{60}/D_{10} is 50.8 mm/9.525 mm or 5.33, meeting USBR guidance to be less than 10 for internal stability.

It is recommended that the gradation requirements for KDOT Stone for Filter Course, Type III material be used for bedding for all three riprap sizes

UTC Bedding Design

Bedding Thickness

There is no specific guidance for bedding thickness for levees. The levee design EM and flood channel EM do not specify.

Thickness guidance for riprap in flood channels specified thickness of not less than the spherical diameter of the W100 stone or 1.5 times the spherical diameter of the W50 stone (which roughly equals the spherical diameter of the W100 stone). D100 for the specified bedding gradation is 6”.

6” bedding thickness was used for KC Levees design and that is typical for levees in NWK. As levees have performed well for slope protection during flood loadings, 6” bedding thickness is recommended for Upper Turkey Creek

APPENDIX B.7 – FLOODWALL TOE DRAIN DESIGN

Floodwall Toe Drain

Used the example of a buried collector at Argentine and modeled the toe drain as a point in GeoStudio with a boundary condition of water total head equal to the ground surface. With loading to top of wall, I got a flow of approx. 3e-5 cfs/ft of wall length.

At Argentine, flow was two orders of magnitude higher, at 3e-3 cfs/ft of wall length. For that project, civil found that the 15” dia perforated pipe provided laminar flow and had sufficient capacity.

Civil subsequently checked expected flow for this floodwall toe drain (see Appendix C.3) and found that flow is laminar and pipe has sufficient capacity.

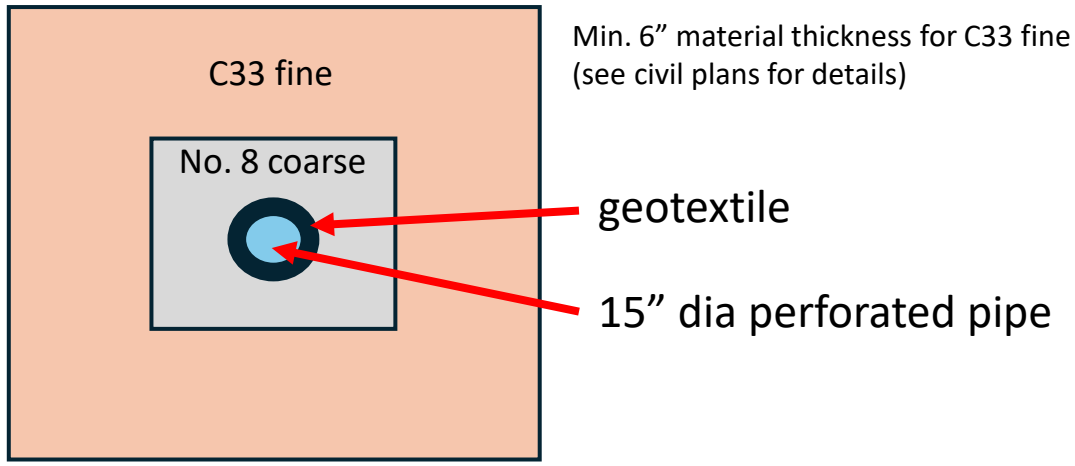
[A] Size number 9 aggregate is defined in Terminology C125 as a fine aggregate. It is included as a coarse aggregate when it is combined with a size number 8 material to create a size number 89, which is a coarse aggregate as defined by Terminology C125.

Toe Drain Filter Compatibility



Min. 6” material thickness for C33 fine and for No. 8 coarse
(see civil plans for details)

Check Perforated Pipe Opening Size limit for ASTM C33 No. 8 Coarse Aggregate

per EM 1110-2-1913, Appendix D (30 April 2000)

Min D_{50} filter material/(hole diameter or slot width) ≥ 1.0

D_{50} of ASTM C33 No. 8 Coarse Filter ranges from 6 to 7 mm

Hole diameter ≤ 6 mm

AASHTO M294 Class 2 HDPE Type SP Pipe normally allows 5 mm to 10 mm perforations. Based on previous projects, it was difficult to limit hole diameter to 6 mm.

Use geotextile to provide filter compatibility between perforated pipe and coarse aggregate

U.S.ARMY CORPS OF ENGINEERS - KANSAS CITY DISTRICT

T Wall Load Cases, Strength Design and Serviceability - EM 1110-2-2104

Upper Turkey Creek

Merriam, KS

PURPOSE

The Engineering Manual for the design of Reinforced Hydraulic Concrete Structures states that the loading conditions for the floodwalls is outlined in Engineering Manual 1110-2-2104 for Strength Design for Reinforced Concrete Hydraulic Structures. Chapter 3 of EM 1110-2-2104 states that both the strength and serviceability loading requirements of the manual must be met. This package will show that the serviceability loading requirements will govern the design of the floodwalls. The serviceability loading will be used to design the T-wall sections in following calculations in this package.

ASSUMPTIONS AND REFERENCES

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104
- For the 100 year event, the design event for the project, water elevation is assumed to the top of the floodwall and is treated as the Unusual Loading condition. for the usual case; the 10 year event, water is loaded minimally on the foundation of the wall. The hydraulic analysis shows that the 10% event is on the order of several hours in a given year based on H&H analysis and does not reach the stem of the floodwalls. Reference Hydraulic section of the DDR for additional commentary on this. For this analysis the 10 year event is assumed to not load the T-walls.

WALL LAYOUT AND GEOMETRY, SECTION AT CREEK STATION 40+24, 14 FT TALL T-WALL

Concrete Structure

$\gamma_{concrete} := 150\ pcf$ *(unit weight of concrete)*

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(saturated unit weight of soil)*

$Elev_{wall} := 920.12\ ft$ *(elevation at top of stem: ELTS)*

$H_{wall} := 14\ ft$ *(wall height measured from the top of footing: HTS)*

$t_{stem.top} := 1.5\ ft$ *(thickness at top of stem: TTS)*

$t_{stem.bot} := 1.5\ ft$ *(thickness at bottom of stem: TBS)*

$t_{stem.batter} := t_{stem.bot} - t_{stem.top} = 0\ in$ *(distance of batter for stem: TBSR)*

$Elev_{foun.top} := Elev_{wall} - H_{wall} = 906.1\ ft$ *(elevation of the top of the foundation)*

$Elev_{soil} := 908.86\ ft$ *(elevation of the soil on stem)*

$Elev_{key} := 900.62\ ft$ *(elevation of the bottom of the key)*

$Elev_{soilwedge} := 907.72\ ft$

$H_{stem} := Elev_{wall} - Elev_{soil} = 11.3\ ft$ *(exposed height of stem above ground level)*

STRENGTH DESIGN LOAD CASES

Permanent Loads

Effective Lateral Earth Pressure: Driving Side

$\rho_{soil.key} := 0.213\ \frac{kip}{ft}$ *(soil lateral loading at base of key, from CTWALL)*

$Elev_{soil} - Elev_{foun.top} = 2.7\ ft$ *(depth of maximum lateral soil loading)*

$\rho_{soil.stem.d} := \rho_{soil.key} \cdot \frac{\left(Elev_{soil} - Elev_{foun.top}\right)}{\left(Elev_{soil} - Elev_{key}\right)} = 0.071 \ \frac{kip}{ft}$ *(lateral soil loading at the top of foundation, bottom of stem)*

$EH_d := \rho_{soil.stem.d} \cdot 0.5 \cdot \left(Elev_{soil} - Elev_{foun.top}\right) = 0.097 \ kip$ *(lateral soil loading, driving side)*

$(x)_{EH.d} := \frac{1}{3} \cdot \left(Elev_{soil} - Elev_{foun.top}\right) = 0.9 \ ft$ *(resultant height above base of stem)*

Effective Lateral Earth Pressure: Resisting Side

$\rho_{soil.foun.bot} := 0.131 \ \frac{kip}{ft}$ *(soil lateral loading at bottom of foundation, from CTWALL)*

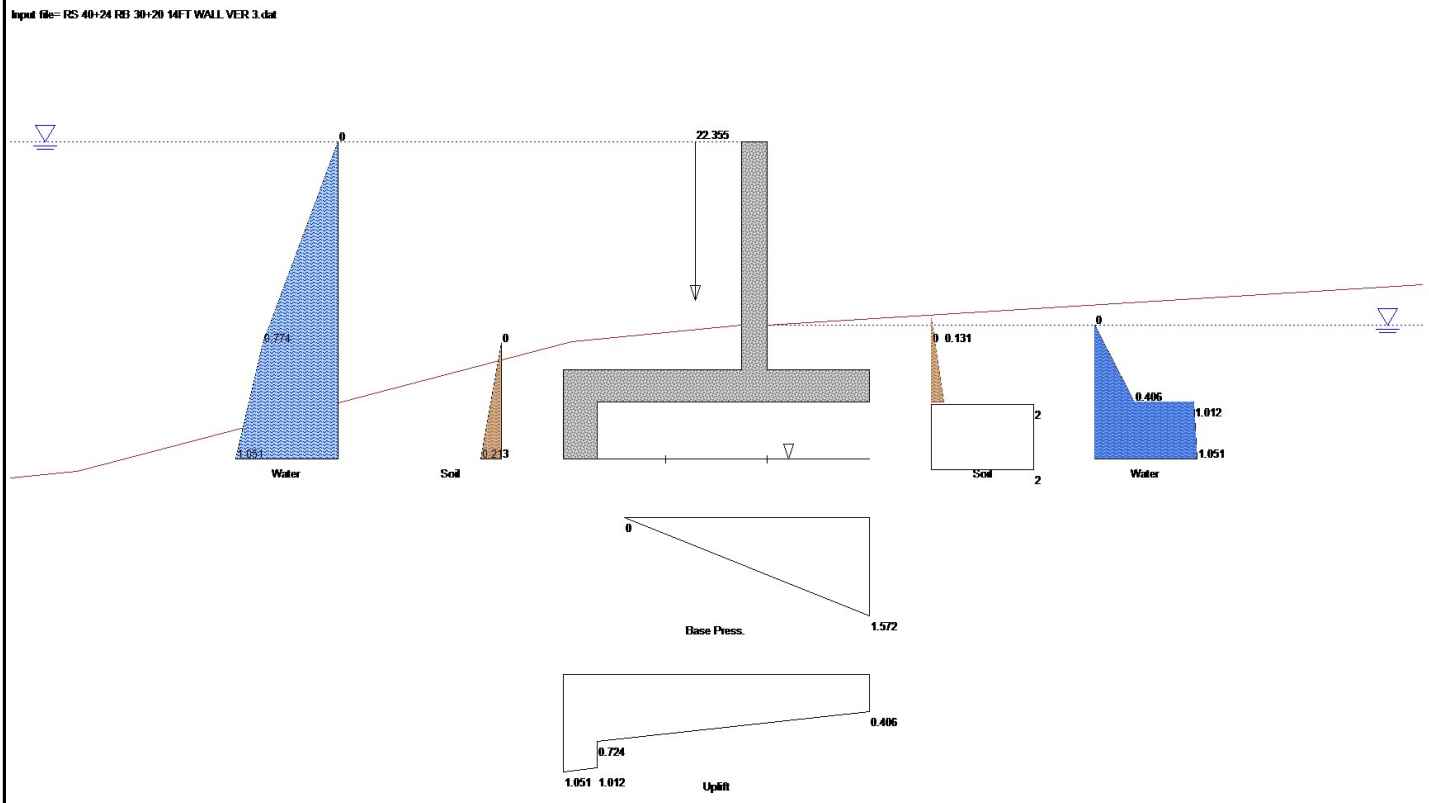
$Elev_{soil} - Elev_{foun.top} = 2.7 \ ft$ *(depth of maximum lateral soil loading)*

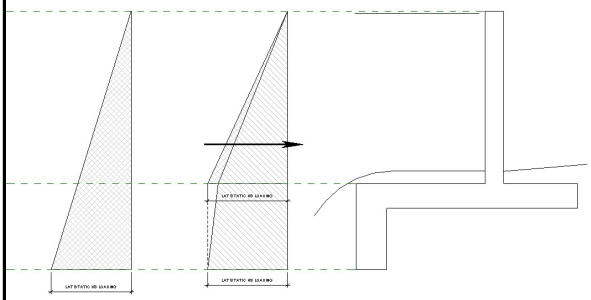
$EH_r := \rho_{soil.foun.bot} \cdot 0.5 \cdot \left(Elev_{soil} - Elev_{foun.top}\right) = 0.179 \ kip$ *(usual lateral soil loading, resisting side)*

$(x)_{EH.r} := \frac{1}{3} \left(Elev_{soil} - Elev_{foun.top}\right) = 0.9 \ ft$ *(resultant height above base of stem)*

Note: reference attached CTWALL printouts for effective lateral earth pressures to the stem of floodwalls.

Reference calculations for the derivation of the lateral static hydraulic pressure. Static hydraulic pressure is calculated assuming that the full fluid pressure at the elevation of the top of the foundation applied to the stem. This provides a conservative estimate of the resultant of the hydraulic loading to the stem without the reduction for the soil's reduction for pore pressure.





Temporary Loading

Hydrostatic Loading - Driving Side

Note: For simplicity water loading assumed to the top of the wall for the unusual case, for the usual case water assumed to not load the stem of the wall.

$\rho_{H.us} := 0.0\ \frac{kip}{ft}$ *(calculated pore pressure to driving side of stem, usual case, assumed 0)*

$\rho_{H.un} := \gamma_{water} \cdot \left(Elev_{wall} - Elev_{foun.top}\right) \cdot 1\ ft = 0.874\ \frac{kip}{ft}$ *(calculated pore pressure to driving side of stem, unusual case)*

$Hs_{us.d} := \rho_{H.us} \cdot 0.5 \cdot \frac{\left(Elev_{wall} - Elev_{foun.top}\right)}{2} = 0\ kip$ *(usual hydrostatic loading or companion load, 10 yr event)*

$(x)_{Hs.us.d} := \frac{1}{3} \cdot \frac{\left(Elev_{wall} - Elev_{foun.top}\right)}{2} = 2.3\ ft$ *(resultant height above base of stem, usual loading driving side)*

$Hs_{un.d} := \rho_{H.un} \cdot 0.5 \cdot \left(Elev_{wall} - Elev_{foun.top}\right) = 6.1\ kip$ *(unusual hydrostatic loading or primary load, 100 yr event)*

$(x)_{Hs.un.d} := \frac{1}{3} \cdot \left(Elev_{wall} - Elev_{foun.top}\right) = 4.7\ ft$ *(resultant height above base of stem, unusual loading driving side)*

Note: the extreme loading even is not considered as the floodwalls are being designed for the 100 year event which is the unusual loading condition

Hydrostatic Loading - Resisting Side

Note: The resisting side hydraulic loading is conservatively assumed to be hydrostatic from the soil surface. Increasing the pressure to include seepage would decrease the demand on the stem.

$\rho_{H.un} := \gamma_{water} \cdot \left(Elev_{wall} - Elev_{foun.top}\right) \cdot 1\ ft = 0.874\ \frac{1}{ft} \cdot kip$ *(calculated pore pressure to driving side of stem, unusual case)*

$Hs_{us.r} := \rho_{H.us} \cdot 0.5 \cdot \frac{\left(Elev_{soil} - Elev_{foun.top}\right)}{2} = 0\ kip$ *(usual hydrostatic loading or companion load, 10 yr event)*

$(x)_{Hs.us.r} := \frac{1}{3} \cdot \frac{\left(Elev_{soil} - Elev_{foun.top}\right)}{2} = 0.5\ ft$ *(resultant height above base of stem, usual loading driving side)*

$Hs_{un.r} := \rho_{H.un} \cdot 0.5 \cdot \left(Elev_{soil} - Elev_{foun.top}\right) = 1.2\ kip$ *(unusual hydrostatic loading or primary load, 100 yr event)*

$(x)_{Hs.un.r} := \frac{1}{3} \cdot \left(Elev_{soil} - Elev_{foun.top}\right) = 0.9\ ft$ *(resultant height above base of stem, unusual loading driving side)*

Note: the extreme loading even is not considered as the floodwalls are being designed for the 100 year event which is the unusual loading condition

Temporary Loads

Peak Hydrostatic Load

$Hs_{peak} := Hs_{un.d}$ *(principle hydrostatic load; maximum differential physically possible on wall)*

Expansion of Ice

Note: Ice loading not included in analysis, reference DDR documentation.

Soil Surcharge

Note: Soil surcharge loading is not included in this calculation. Loading in applicable in certain locations, but does not contribute significantly to the loading condition that governs design. For the strength vs serviceability comparison only load case 1 per Table E-3 of EM 1110-2-2104 will govern design.

Dynamic Loading

Hydrodynamic Loading

Note: Reference DDR section for Hydrodynamic loading as well as the analysis in this document. Hydrodynamic loading considerations excluded as flows are parallel to the face of the floodwall.

Wave Loading

Note: wave loading not considered as fetch lengths are too short and water velocities are perpendicular to the wall in most instances.

Debris Loading

$I_{us} := 0\ kip$ *(impact loading, EM 1110-2-2502 6.12.3)*

$I_{un} := 0.1\ kip$ *(impact loading, EM 1110-2-2502 6.12.3)*

Wind Loading

Note: Wind loading only applicable while water not loaded to the top of floodwall. For comparison of the strength and serviceability loading load case 1 with hydrostatic loading to the top of the floodwall considered for analysis.

LOAD FACTORS

Strength Design

Dead Loads

$\gamma_{p.D} := 1.2$ *(load factor - Usual dead load)*

$\gamma_{p.D\_sub} := 0.9$ *(load factor when loads subtract from predominant load effect - Extreme dead load)*

Effective Lateral Earth Loads

$\gamma_{c.EH\_driving} := 1.5$ *(load factor for at-rest pressures, EM 1110-2-2104 3-3d)*

$\gamma_{c.EH\_resisting} := 0.5$ *(load factor for at-rest pressures, EM 1110-2-2104 3-3d)*

Hydrostatic Loading

$(\gamma_{Hs})_c := 1.0$ *(hydrostatic companion loading, EM 1110-2-2104, Table 3-2)*

$(\gamma_{Hs})_{pr.U} := 1.5$ *(hydrostatic principle Usual loading, EM 1110-2-2104, Table 3-2)*

$(\gamma_{Hs})_{pr.N} := 1.4$ *(hydrostatic principle Unusual loading, EM 1110-2-2104, Table 3-2)*

Debris Loading

$(\gamma_{IM})_c := 1.0$ *(debris companion loading, EM 1110-2-2104, Table 3-2)*

$(\gamma_{IM})_{pr.U} := 0$ *(debris principle Usual loading, EM 1110-2-2104, Table 3-2)*

$(\gamma_{IM})_{pr.N} := 1.4$ *(debris principle Unusual loading, EM 1110-2-2104, 3-3d (2) (b))*

$(\gamma_{IM})_{pr.X} := 1.3$ *(debris principle Extreme loading, EM 1110-2-2104, Table 3-2)*

Serviceability Design

$\Phi_{us} := 2.2$ *(serviceability single load case factor for usual flexural and shear loading, EM 1110-2-2104 Table 3-4*

$\Phi_{un} := 1.6$ *(serviceability single load case factor for unusual flexural and shear loading, EM 1110-2-2104 Table 3-4*

STRENGTH LOADING COMBINATIONS

Permanent Loadings

Driving Side

$(\Sigma\gamma_p L_p)_{driving} := \gamma_{c.EH\_driving} \cdot EH_d = 145.6\ lbf$ *(factored driving side permanent loading)*

Resisting Side

$(\Sigma\gamma_p L_p)_{resisting} := \gamma_{c.EH\_resisting} \cdot EH_r = 89.7\ lbf$ *(factored resisting side permanent loading)*

Temporary Loadings

Note: the controlling load combination contains hydrostatic pressure as the principle loading condition. The hydrostatic water level on the resisting side of the wall is to the ground surface.

Driving Side

$(\Sigma\gamma_{pr} L_{tpr})_{driving} := (\gamma_{Hs})_{pr.U} \cdot Hs_{un.d} = 9172.8\ lbf$ *(factored driving side temporary loading)*

Resisting Side

$(\Sigma\gamma_{pr} L_{tpr})_{resisting} := (\gamma_{Hs})_{pr.U} \cdot Hs_{un.r} = 1795.2\ lbf$ *(factored driving side temporary loading)*

Dynamic Loadings

Driving Side

$(\Sigma\gamma_c L_{dc})_{driving} := (\gamma_{IM})_{pr.N} \cdot I_{un} = 140\ lbf$ *(factored driving side temporary loading)*

Resisting Side

Note: there are no applicable dynamic loads to the resisting side of the floodwall

$(\Sigma\gamma_c L_{rc})_{resisting} := 0\ lbf$ *(factored driving side temporary loading)*

Strength Level Shear Combination

$$(LC_{Str})_{shear} := (\Sigma\gamma_p L_p)_{driving} + (\Sigma\gamma_{pr} L_{tpr})_{driving} + (\Sigma\gamma_c L_{dc})_{driving} - (\Sigma\gamma_p L_p)_{resisting} - (\Sigma\gamma_{pr} L_{tpr})_{resisting} - (\Sigma\gamma_c L_{rc})_{resisting} = 7.6\ kip$$

(factored shear loading for T-wall stem at strength level)

Strength Level Moment Combination

$$(LC_{Str})_{moment} := \left((\Sigma\gamma_p L_p)_{driving} \cdot (x)_{EH.d}\right) + \left((\Sigma\gamma_{pr} L_{tpr})_{driving} \cdot (x)_{Hs.un.d}\right) + \left((\Sigma\gamma_c L_{dc})_{driving} \cdot H_{wall}\right) - \left((\Sigma\gamma_p L_p)_{resisting} \cdot (x)_{EH.r}\right) - \left((\Sigma\gamma_{pr} L_{tpr})_{resisting} \cdot (x)_{Hs.un.r}\right) - \left((\Sigma\gamma_c L_{rc})_{resisting} \cdot H_{wall}\right) = 43.2\ kip \cdot ft$$

(factored moment loading for T-wall stem at strength level)

SERVICEABILITY LIMITS

Permanent Loads

Effective Lateral Earth Pressure: Driving Side

$EH_d = 0.097\ kip$ *(usual lateral soil loading, driving side)*

$EH_d = 0.097\ kip$ *(unusual lateral soil loading, driving side)*

Effective Lateral Earth Pressure: Resisting Side

$EH_r = 0.179\ kip$ *(usual lateral soil loading, resisting side)*

$EH_r = 0.179\ kip$ *(unusual lateral soil loading, resisting side)*

Temporary Loadings

Hydrostatic Loading - Driving Side

$Hs_{us.d} = 0\ kip$ *(usual hydrostatic loading or companion load, 10 yr event)*

$Hs_{un.d} = 6.1\ kip$ *(unusual hydrostatic loading or primary load, 100 yr event)*

Hydrostatic Loading - Resisting Side

$Hs_{us.r} = 0\ kip$ *(usual hydrostatic loading or companion load, 10 yr event)*

$Hs_{un.r} = 1.2\ kip$ *(unusual hydrostatic loading or primary load, 100 yr event)*

Dynamic Loading

Debris Loading

$I_{us} = 0\ kip$ *(impact loading, EM 1110-2-2502 6.12.3)*

$I_{un} = 0.1\ kip$ *(impact loading, EM 1110-2-2502 6.12.3)*

Serviceability Level Shear Combinations

$$(LC_{Ser})_{shear} := \Phi_{us} \cdot \left(EH_d + Hs_{un.d} + I_{un}\right) - \Phi_{us} \cdot \left(EH_r + Hs_{un.r}\right) = 10.9\ kip$$

(factored shear loading for T-wall stem at serviceability level)

Serviceability Level Moment Combinations

$$(LC_{Ser})_{moment} := \Phi_{us} \cdot \left(\left(EH_d \cdot (x)_{EH.d}\right) + \left(Hs_{un.d} \cdot (x)_{Hs.un.d}\right) + \left(I_{un} \cdot H_{wall}\right)\right) - \Phi_{us} \cdot \left(\left(EH_r \cdot (x)_{EH.r}\right) + \left(Hs_{un.r} \cdot (x)_{Hs.un.r}\right)\right) = 63.3\ ft \cdot kip$$

(factored shear loading for T-wall stem at serviceability level)

COMPARISON SHEAR AND MOMENT FORCES

Strength Level Loading	Serviceability Level Loading
$(LC_{Str})_{shear} = 7.6\ kip$	$(LC_{Ser})_{shear} = 10.9\ kip$
$(LC_{Str})_{moment} = 43.2\ kip \cdot ft$	$(LC_{Ser})_{moment} = 63.3\ kip \cdot ft$

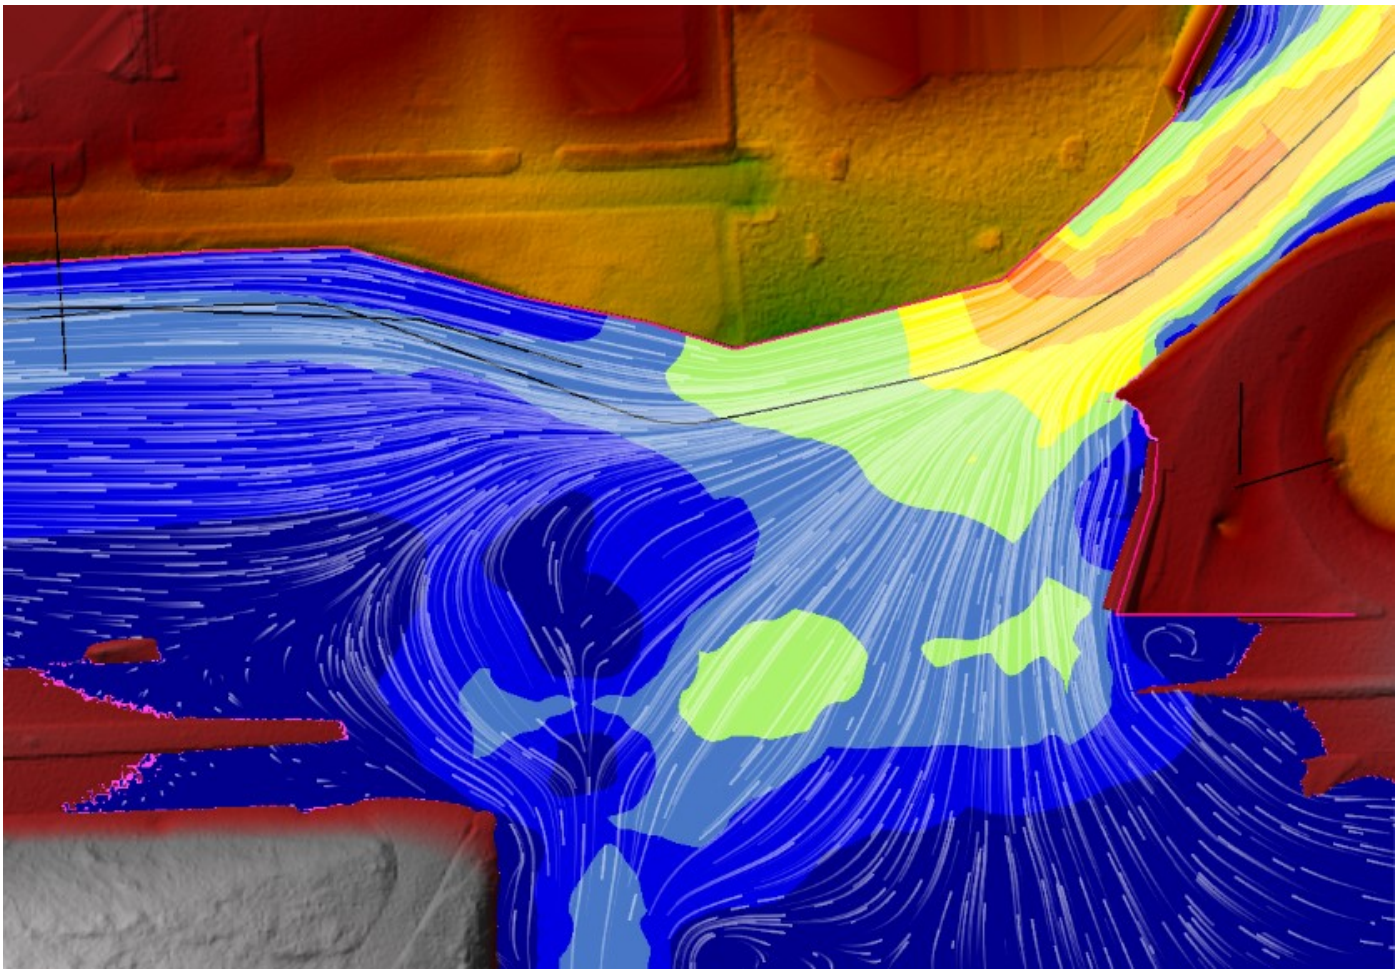
Note: The results show that using the single load factor for serviceability controls over the strength design factors. For the remainder of the design checks, the Serviceability level loadings will be used to size t-wall sections.

IMPACT LOADING

Note: Per EM 1110-2-2502 section 6.12.3 the impacting loading to the tops of T-walls should be considered to be between 100 lbs per foot and 500 lbs per foot depending on the site conditions and wall layout. for the Upper Turkey Creek corridor, channel flows are parallel, or nearly parallel to the face of the wall and thus impact loads would only come from glancing blows from objects being carried through the waterway.

One exception at the confluence between the tributary and Upper Turkey Creek approximately where Shawnee Mission Parkway meets Merriam Drive was reviewed as the T-wall on the left bank appears to be nearly perpendicular to the flow from Turkey Creek. However, after reviewing the velocity vector map provided by the Hydraulics and Hydrology model it can be seen that the flows here are also nearly parallel to the face of the wall.

Per engineering judgement and this analysis, impact loading applied to the top of the wall will be 100 lbs per foot for all wall sections being analyzed.



U.S.ARMY CORPS OF ENGINEERS - KANSAS CITY DISTRICT

T-Wall Load Cases and Strength Design

Upper Turkey Creek

Merriam, KS

ASSUMPTIONS

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

FLOOD LOAD CASES

Unusual Case

Top of Wall, ACE = 100 year event, Unusual Case

WSE = Top of Protection

Usual Case

ACE = 10 year event, Usual Case

WSE elevation below the top of the foundation

Note: The Unusual Flood Case with water to the top of the wall governs the design of this floodwall. Non-flood condition loads such as construction, seismic and wind are addressed in the stem design; however, it is apparent that the top of wall flood condition governs stability and the primary steel design so only the Unusual top of wall flood load is considered for stability and the base design.

The Usual Flood Case does not have water to the top of the foundation and is not included in these calculations.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$\gamma'_{soil} := \gamma_{soil} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$q_n := 2000\ psi$ *(bearing pressure, Reference DDR Table 9.2)*

Drained Soil Conditions

$\phi_{drained} := 28\ deg$ *(internal friction angle for drained soil condition)*

$C_{drained} := 0\ psf$ *(cohesion for drained soil condition)*

$k_0 := 1 - \sin\left(\phi_{drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

Undrained Soil Conditions

$\phi_{undrained} := 0\ deg$ *(internal friction angle for drained soil condition)*

$C_{undrained} := 1000\ psf$ *(cohesion for drained soil condition)*

$(k_0)_{undrained} := 1 - \sin\left(\phi_{undrained}\right) = 1$ *(at-rest soil pressure coefficient for the undrained condition)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(young's modulus of elasticity for steel)*

$(F_y)_{30} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$(F_y)_{60} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$\varepsilon_{ty} := \frac{(F_y)_{60}}{E_{steel}} = 0.0021$ *(yield strain of 60 ksi steel)*

Concrete Properties

$f'_c := 4500\ psi$ *(concrete compressive strength for all structures)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength for all structures)*

$q\lambda_c := 1.0$ *(concrete modification factor)*

$cover_3 := 3\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$cover_4 := 4\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$\gamma_{conc} := 150\ pcf$ *(concrete unit weight)*

$Ec := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$ *(young's modulus of elasticity for concrete)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

Load Factors

Serviceability Load Factors

Note: the unusual loading condition is used for the top of the floodwalls since they are designed to the 100 year event. the usual loading condition is defined as the 10 year event.

$(\gamma_p)_{Serve.u} := 2.2$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

$(\gamma_p)_{Serve.n} := 1.6$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

Strength Limit States

$\phi_b := 0.9$ *(bending load reduction factor - ACI 318-19 21.2.2, Table 21.2.2)*

$\phi_A := 0.9$

$\phi_V := 0.75$ *(shear load reduction factor - ACI 318-19 Table 21.2.1)*

Lateral Earth Loading

$\sigma_{EHd} := \begin{bmatrix} 0.202 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side, bottom of key; Drained, Undrained)*

$\sigma_{EHr} := \begin{bmatrix} 0.128 \\ 0.204 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side, bottom of foundation at toe; Drained, Undrained)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} := \begin{bmatrix} 1.41 \\ 1.13 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation; Drained, Undrained)*

$(\sigma_{EH})_{bh.bot} := \begin{bmatrix} 1.41 \\ 1.13 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key, Drained, Undrained)*

Impact Loading

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

Soil Pressure

$(\sigma_{SP})_{max} := -\begin{bmatrix} 1.405 \\ 1.425 \end{bmatrix} ksf$ *(max base soil loading from CT Wall Output)*

Uplift Pressure

$UL_1 := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$(\sigma_{UL})_{min} := UL_4 = \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(minimum uplift pressure at the end of the toe)*

$(\sigma_{UL})_{max} := UL_3 = \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(maximum uplift pressure behind the key)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

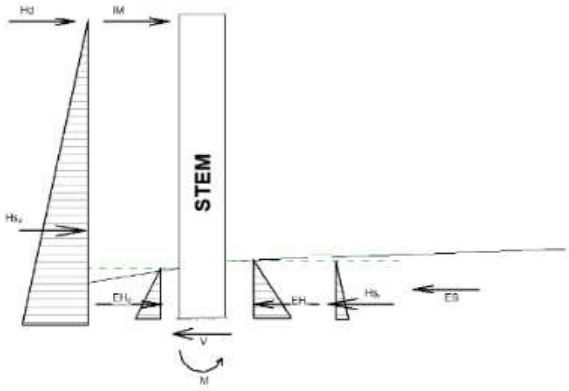
$(\sigma_{Hs})_{bh.bot} := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

STEM DESIGN, RIVER SIDE

Loads to Stem

Note: largest loading from drained and undrained cases used to determine the controlling load case. In each loading condition, drained loads are listed first and undrained last.

This design for the riverside steel, along with the EnerCalc calculations, attached will be used for the landside steel design for simplicity. By inspection, the riverside reinforcement is sufficient for the landside reinforcement design.



Hydrostatic Loads

$\sigma_{Hsd} := \begin{bmatrix} \gamma_{water} \cdot HTS \\ \gamma_{water} \cdot HTS \end{bmatrix} = \begin{bmatrix} 873.6 \\ 873.6 \end{bmatrix} psf$ *(hydrostatic pressure loading to driving side)*

$Hs_d := \overrightarrow{0.5 \cdot \sigma_{Hsd} \cdot HTS} = \begin{bmatrix} 6.115 \\ 6.115 \end{bmatrix} klf$ *(hydrostatic loading to driving side)*

$(x_{Hs})_d := HTS \cdot \frac{1}{3} = 4.7\ ft$ *(moment arm for hydrostatic loading to the driving side from the base of the stem)*

Note: assume that hydrostatic loading from the resisting side of the T-wall provided from groundwater up to the ground surface. Assume that all additional water from the resisting side, landside, of the floodwall is conveyed away through interior drainage systems.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 0.18 \\ 0.18 \end{bmatrix} ksf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{0.5 \cdot \sigma_{Hsr} \cdot HSR} = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} klf$ *(hydrostatic loading to resisting side)*

$(x_{Hs})_r := HSR \cdot \frac{1}{3} = 0.96\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Lateral Earth Loading

$(\sigma_{EHd})_{stem} := \sigma_{EHd} \cdot \left(\frac{HSD}{HSD + THEEL} \right) = \begin{bmatrix} 0.069 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side of stem)*

$EH_d := \overrightarrow{0.5 \cdot (\sigma_{EHd})_{stem} \cdot HSD} = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to driving side of stem)*

$(x_{EH})_d := HSD \cdot \frac{1}{3} = 1\ ft$ *(moment arm for lateral earth loading to the driving side from the base of the stem)*

$(\sigma_{EHr})_{stem} := \sigma_{EHr} \cdot \frac{HSR}{HSR + TTOE} = \begin{bmatrix} 0.076 \\ 0.12 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side of stem)*

$EH_r := \overrightarrow{0.5 \cdot (\sigma_{EHr})_{stem} \cdot HSR} = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix} klf$ *(lateral earth loading to resisting side of stem)*

$(x_{EH})_r := HSR \cdot \frac{1}{3} = 1\ ft$ *(moment arm for lateral earth loading to the resisting side from the base of the stem)*

Impact Loading

Note: reference DDR for discussion of impact loading on floodwalls.

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

$(x_{IM})_d := HTS = 14\ ft$ *(moment arm of the impact load from the base of the stem)*

Operating Equipment

$p_{const} := 250\ psf$ *(construction surcharge loading)*

Note: assume that the surcharge loading is uniform and that the resultant is mid-height of the soil depth.

$d_{soil} := HSR = 2.9\ ft$ *(depth of soil cover on stem)*

$(x_Q)_d := \frac{HSR}{2} = 1.4\ ft$ *(resultant height above base of stem)*

$x_Q := d_{soil} - (x_Q)_d = 1.4\ ft$ *(depth from resultant to top of soil)*

$\sigma_H := p_{const} \cdot k_0 = 0.133\ ksf$ *(lateral linear pressure applied to wall)*

$Q := \sigma_H \cdot HSR = 0.382\ klf$ *(lateral surcharge load to structure, usual case)*

Wind

Note: for conservative analysis, wind loading only applied to the driving side as a positive pressure or applied to the resisting side as a negative pressure.

$(p_w)_p := 30.4\ psf$ *(primary wind pressure, reference DDR)*

$(p_w)_c := 15.8\ psf$ *(companion wind pressure, reference DDR)*

$G := 0.85\ \frac{1}{ft}$ *(gust factor, ASCE 7-16 Section 26.11.1)*

$C_f := 1.3$ *(force coefficient from ASCE 7-16, figure 29.3-1, s/h = 1 and B/s = '>45')*

$d := HTS - HSR = 11.1\ ft$ *(exposed surface of the stem for wind pressure)*

$A_s := 1\ ft \cdot d = 11.1\ ft^2$ *(exposed surface area of the wall per linear foot)*

$W_c := (p_w)_c \cdot G \cdot C_f \cdot A_s = 0.194\ klf$ *(wind loading, usual case for companion loading)*

$W_p := (p_w)_p \cdot G \cdot C_f \cdot A_s = 0.374\ klf$ *(wind loading, unusual case)*

$(x_W)_d := HTS - \frac{d}{2} = 8.4\ ft$ *(resultant height above base of stem)*

Earthquake Loading: Equivalent Lateral Force

$D_{wall} := (TTS \cdot HTS) \cdot \gamma_{conc} = 3.2\ \frac{1}{ft} \cdot kip$ *(dead load of the stem of the wall)*

$I_e := 1.5$ *(importance factor, ASCE 7-16 Table 1.5-2)*

$R := 2.5$ *(response modification factor, ASCE 7-16, Table 12.2-1, Item G.3)*

$S_{DS} := 0.101$ *(seismic spectral acceleration for short period)*

$Cs := \frac{S_{DS}}{\frac{R}{I_e}} = 0.1$ *(seismic response coefficient, ASCE 7-16 12.8-2)*

$V := Cs \cdot D_{wall} = 0.2\ klf$ *(seismic base shear, ASCE 7-16, EQ 12.8-1)*

$EQ := V = 0.2\ klf$

$(x_{EQ}) := HSR = 2.9\ ft$ *(resultant height above base of stem)*

Load Combinations

Note: Usual design cases not considered here as the Usual pool level does not reach the base of the stem.

Driving Side Forces

$LC1_d := (\gamma_p)_{Serve.n} \cdot \langle EH_d + Hs_d + IM \rangle = \begin{bmatrix} 10.1 \\ 9.9 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \langle EH_d + EQ \rangle = \begin{bmatrix} 0.5 \\ 0.3 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \langle EH_d + Q \rangle = \begin{bmatrix} 0.8 \\ 0.6 \end{bmatrix} klf$ *(load case 3 for construction)*

Resisting Side Forces

$LC1_r := (\gamma_p)_{Serve.n} \cdot \langle EH_r + Hs_r - W_c \rangle = \begin{bmatrix} 0.3 \\ 0.4 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \langle EH_r \rangle = \begin{bmatrix} 0.2 \\ 0.3 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \langle EH_r \rangle = \begin{bmatrix} 0.2 \\ 0.3 \end{bmatrix} klf$ *(load case 4 for construction)*

Resultant Shear at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 9.8 \\ 9.6 \end{bmatrix} klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.3 \\ 0 \end{bmatrix} klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.6 \\ 0.3 \end{bmatrix} klf$ *(equilibrium load case 3)*

$\Sigma F_{stem} := \text{stack}(LC1, LC2, LC3)$

Note: Maximum factored shear loading to the stem is the governing loading for the river side steel design. Minimum factored shear loading is the governing landside steel design.

$(Vu)_{stem} := \max(\Sigma F_{stem}) = 9.8\ klf$ *(resultant factored shear at base of floodwall stem, driving side)*

Resultant Moment - Driving Side

$LC1_d := (\gamma_p)_{Serve.n} \cdot (\langle EH_d \cdot (x_{EH})_d \rangle + \langle Hs_d \cdot (x_{Hs})_d \rangle + IM \cdot (x_{IM})_d \rangle = \begin{bmatrix} 48.1 \\ 47.9 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot (\langle EH_d \cdot (x_{EH})_d \rangle + \langle EQ \cdot (x_{EQ}) \rangle) = \begin{bmatrix} 1 \\ 0.9 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot (\langle EH_d \cdot (x_{EH})_d \rangle + \langle Q \cdot \langle (x_Q)_d \rangle \rangle) = \begin{bmatrix} 1 \\ 0.9 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction)*

Resultant Moment - Resisting Side

$LC1_r := (\gamma_p)_{Serve.n} \cdot (\langle EH_r \cdot (x_{EH})_r \rangle + \langle Hs_r \cdot (x_{Hs})_r \rangle) = \begin{bmatrix} 0.6 \\ 0.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum flooding)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot (\langle EH_r \cdot (x_{EH})_r \rangle) = \begin{bmatrix} 0.2 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot (\langle EH_r \cdot (x_{EH})_r \rangle) = \begin{bmatrix} 0.2 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction or surcharge loading)*

Resultant Moment at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 47.5 \\ 47.2 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.9 \\ 0.6 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.9 \\ 0.6 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 3)*

$\Sigma M_{stem} := \text{stack}(LC1, LC2, LC3)$ *(resultant factored moment at base of floodwall stem)*

$(Mu)_{stem} := \max(\Sigma M_{stem}) \cdot 1\ ft = 47.5\ kip \cdot ft$ *(resultant moment at base of floodwall stem, riverside steel design)*

Design Check Function

(system check for capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing arrays)

$$Check_v(X_U, X_N) := \left| \begin{array}{l} \text{for } i \in \text{ORIGIN} .. \text{last}(X_U) \\ \quad \left| \begin{array}{l} \text{if } X_{U_i} > X_{N_i} \\ \quad \left| \begin{array}{l} ch_{i,1} \leftarrow \text{“NO GOOD”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \\ \text{else if } X_{N_i} = 0 \\ \quad \left| ch_{i,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left| \begin{array}{l} ch_{i,1} \leftarrow \text{“OK”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing scalar values)

$$Check(X_U, X_N) := \left| \begin{array}{l} \text{if } X_U > X_N \\ \quad \left| \begin{array}{l} ch_{1,1} \leftarrow \text{“NO GOOD”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ \text{else if } X_U = 0 \\ \quad \left| ch_{1,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left| \begin{array}{l} ch_{1,1} \leftarrow \text{“OK”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

$b := 12\ in$ *(strip width for analysis)*

Stem Reinforcement

Vertical Bars

$(d_b)_{stem.vert} :=$ Bar Size: #8 $= 1\ in$ *(vertical bar size in stem)*

$s_{stem.vert} := 12\ in$ *(vertical bar spacing in stem)*

$c_{stem.vert} :=$ 3″ cover *(cover for vertical reinforcement in stem)*

$$(A_s)_{stem.vert} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.vert}^{\ 2} \cdot b}{s_{stem.vert}} = 0.785\ in^2$$ *(area of steel vertical reinforcement in stem)*

$d_{stem.vert} := TTS - c_{stem.vert} - (0.5 \cdot (d_b)_{stem.vert}) = 14.5\ in$ *(depth to reinforcement vertical reinforcement in stem)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{stem} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$$a_{stem.vert} := \frac{(A_s)_{stem.vert} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}} = 0.85\ in$$

(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)

$$(\phi M_n)_{stem.vert} := \phi_b \cdot (A_s)_{stem.vert} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{a_{stem.vert}}{2}\right) = 49.7\ kip \cdot ft$$

(nominal flexural strength, EM1110-2-2104, B-49)

$$(Flex_{nom})_{Stem} := Check\left((Mu)_{stem}, (\phi M_n)_{stem.vert}\right) = [\text{"OK"} \quad 0.95]$$

(nominal flexural check, with Utilization ratio)

Minimum Required Steel for Flexure

Solve Constraints Given Values

$$As_{req} := 1.5\ in^2$$

$$(Mu)_{stem} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$$

$$As_{req.stem} := \text{find}\left(As_{req}\right) = 0.772\ in^2$$

$$(A_{s.min})_{stem.ten} := As_{req.stem} = 0.772\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.584\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.58\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTS \cdot b) = 0.324\ in^2$$

(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$

(minimum area of steel required for flexural capacity)

$$A_{s.min} = 0.584\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{stem.ten} \cdot \frac{4}{3} = 1.03\ in^2$$

(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)

$$(A_s)_{stem.req} := \begin{cases} as \leftarrow (A_{s.min})_{stem.ten} & \text{if } A_{s\_1.3} < (A_s)_{stem.vert} \\ as \leftarrow A_{s.min} & \text{else} \end{cases} = 0.584\ in^2$$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{stem.vert} = 0.8\ in^2$$

(area of steel provided in the vertical direction for the stem)

$$(Steel\_Check_{Vert})_{Stem} := Check\left((A_s)_{stem.req}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.7]$$

(check stem reinforcement to required reinforcement)

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Vert.ts})_{Stem} := Check\left((A_{s.min})_{temp}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$ *(check stem reinforcement to temperature and shrinkage requirements)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{stem.vert}}{\left(b \cdot d_{stem.vert}\right)} = 0.0045$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{Stem} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{stem.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in stem)*

$s_{stem.lat} := 12\ in$ *(lateral bar spacing in stem)*

$(A_s)_{stem.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.lat}^{\ 2} \cdot 12\ in}{s_{stem.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in stem)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot \left(TTS \cdot b\right)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.3\ in^2$

$(A_s)_{stem.lat} = 0.4\ in^2$ *(area of steel provided in the lateral direction for the stem)*

$(Steel\_Check_{Lat})_{Stem} := Check\left(A_{s.req}, (A_s)_{stem.lat}\right) = [\text{"OK"} \quad 0.7]$ *(check stem reinforcement to required reinforcement)*

Riverside Reinforcement

Primary Reinforcement

$(d_b)_{stem.vert} = 1\ in$ *bars located at* $s_{stem.vert} = 12\ in$ *centers*

Lateral Reinforcement

$(d_b)_{stem.lat} = 0.75\ in$ *bars located at* $s_{stem.lat} = 12\ in$ *centers*

Deflection Check

Note: Reference provided justification file for loading conditions and attached EnerCalc calculations for the deflections in floodwall stem since stem thickness is less than H/8. From EnerCalc report, wall deflections limited to H/6838, which is less than expected movement capacity in waterstop and wall joints. 14 ft tall floodwalls to have stems with above detailed reinforcement.

Landside Reinforcement

For design simplicity, landside reinforcement to match both primary and lateral reinforcement.

STEM SHEAR CONNECTION TO FOUNDATION

Shear Friction

$f_y := (F_y)_{60} = 60000\ psi$ *(yield strength of reinforcing steel)*

$\mu := 1.0$

$(d_b)_{stem.vert.2} :=$ Bar Size: #8 $= 1\ in$ *(vertical bar size in stem)*

$s_{stem.vert2} := 12\ in$

$A_{vf} := \left(\frac{\pi}{4}\right) \cdot (d_b)_{stem.vert.2}{}^2 \cdot \left(\frac{b}{s_{stem.vert2}}\right) = 0.8\ in^2$

$V_n := \mu \cdot A_{vf} \cdot f_y = 47.1\ kip$ *(shear-friction strength, ACI 318-19, eq 22.9.4.2)*

Table 22.9.4.2—Coefficients of friction

Contact surface condition	Coefficient of friction μ[1]	
Concrete placed monolithically	1.4λ	(a)
Concrete placed against hardened concrete that is clean, free of laitance, and intentionally roughened to a full amplitude of approximately 1/4 in.	1.0λ	(b)
Concrete placed against hardened concrete that is clean, free of laitance, and not intentionally roughened	0.6λ	(c)
Concrete placed against as-rolled structural steel that is clean, free of paint, and with shear transferred across the contact surface by headed studs or by welded deformed bars or wires.	0.7λ	(d)

[1]λ = 1.0 for normalweight concrete. For lightweight concrete, λ is calculated as given in 19.2.4, but shall not exceed 0.85.

Table 22.9.4.4—Maximum V_n across the assumed shear plane

Condition	Maximum V_n		
Normalweight concrete placed monolithically or placed against hardened concrete intentionally roughened to a full amplitude of approximately 1/4 in.	Least of (a), (b), and (c)	$0.2f'_cA_c$	(a)
		$(480 + 0.08f'_c)A_c$	(b)
		$1600A_c$	(c)
Other cases	Lesser of (d) and (e)	$0.2f'_cA_c$	(d)
		$800A_c$	(e)

Maximum Shear Friction

$A_c := b \cdot TTS = 1.5\ ft^2$

$(V_n)_a := 0.2\ f'_c \cdot A_c = 194.4\ kip$ *(shear-friction maximum, equation a, Table 22.9.4.4)*

$(V_n)_b := \left(480\ psi + 0.08 \cdot f'_c\right) \cdot A_c = 181.4\ kip$ *(shear-friction maximum, equation b, Table 22.9.4.4)*

$(V_n)_c := \left(16000\ psi\right) A_c = 3456\ kip$ *(shear-friction maximum, equation c, Table 22.9.4.4)*

$(V_n)_{max} := \max\left((V_n)_a, (V_n)_b, (V_n)_c\right) = 3456\ kip$ *(shear-friction maximum, Table 22.9.4.4)*

Shear Strength

$\phi_V = 0.75$ *(reduction factor for shear capacity)*

$\phi_V V_n := \phi_V \cdot min\left((V_n)_{max}, V_n\right) = 35.3\ kip$ *(factored shear-friction strength)*

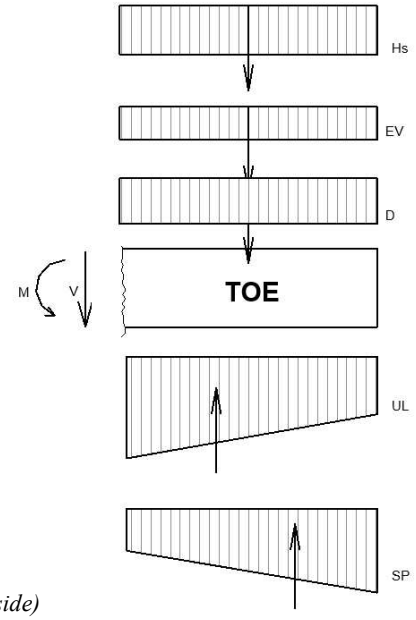
$V_{stem} := (Vu)_{stem} \cdot b = 9.8\ kip$ *(calculated shear required at base of stem)*

$V_{check} := Check\left(V_{stem}, \phi_V V_n\right) = [\text{“OK”}\ \ 0.3]$ *(shear check, utilization ratio)*

Toe Check

Loads to Toe

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



Dead Load

$\sigma_D := \gamma_{conc} \cdot TTOE = 300\ psf$

$D := \sigma_D \cdot TWIDTH = 1.8\ klf$ *(resultant dead load of toe)*

$(x_D)_{toe} := \frac{TWIDTH}{2} = 3\ ft$ *(moment arm of the dead loading from the connection of the toe to the foundation)*

Hydrostatic Loads Above Toe

Note: Groundwater assumed to the soil surface. Potential additional seepage pressure conservatively ignored.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 179.7 \\ 179.7 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{TWIDTH \cdot \sigma_{Hsr}} = \begin{bmatrix} 1.1 \\ 1.1 \end{bmatrix} klf$ *(Resultant hydrostatic loading to resisting side)*

$(x_{Hs})_r := TWIDTH \cdot 0.5 = 3\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Vertical Earth Pressure

$\sigma_{EV} := \gamma'_{soil} \cdot HSR = 165.9\ psf$

$EV_r := \begin{bmatrix} \sigma_{EV} \cdot TWIDTH \\ \sigma_{EV} \cdot TWIDTH \end{bmatrix} = \begin{bmatrix} 0.995 \\ 0.995 \end{bmatrix} klf$ *(buoyant force of vertical soil loading)*

$(x_{EV})_r := \frac{TWIDTH}{2} = 3\ ft$

Soil Pressure

$(\sigma_{SP})_{max} = \begin{bmatrix} -1.405 \\ -1.425 \end{bmatrix} ksf$ *(max soil loading from CT Wall Output)*

$BWIDTH = 18\ ft$ *(total length of base of wall)*

$BIC_{percent} := \begin{bmatrix} 89.61 \\ 75.35 \end{bmatrix}\%$ *(percent of the base in compression)*

$BIC := BWIDTH \cdot BIC_{percent} = \begin{bmatrix} 16.1 \\ 13.6 \end{bmatrix} ft$ *(length of base in compression)*

$TWIDTH = 6\ ft$ *(length of toe of the foundation)*

note: using the length of the toe to determine the soil loading at the the connection of the toe to the stem and heel, use similar triangles to determine the loading at the connection of the toe.

$NTWIDTH := BIC - TWIDTH = \begin{bmatrix} 10.1 \\ 7.6 \end{bmatrix} ft$ *(length of the not-toe of the foundation in compression)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{NTWIDTH}{(\sigma_{SP})_1}$ *(relationship of similar triangles)*

$(\sigma_{SP})_1 := \overrightarrow{NTWIDTH \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} -0.88 \\ -0.79 \end{bmatrix} ksf$ *(soil pressure loading at the connection of the toe)*

$SP_{toe} := \frac{TWIDTH \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1 \right)}{2} = \begin{bmatrix} -6.9 \\ -6.7 \end{bmatrix} klf$ *(resultant soil loading to the toe of the foundation)*

$$(x_{SP})_{toe} := \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{SP})_{max}\right) + (\sigma_{SP})_1\right)}{3 \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)} = \begin{bmatrix} 3.2 \\ 3.3 \end{bmatrix} ft$$

(moment arm from the connection of the toe to the resultant of the soil pressure loading)

Uplift Pressures

$$(\sigma_{UL})_{min} = \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$$

(minimum uplift pressure at the end of the toe)

$$(\sigma_{UL})_{max} = \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$$

(maximum uplift pressure behind the key)

Note: Uplift pressure drops off linearly from the back of the key to the toe of the foundation

$BWIDTH = 18\ ft$ *(foundation width)*

$TK = 2\ ft$ *(key width)*

$L := BWIDTH - TK = 16\ ft$ *(length of linear uplift pressure)*

$(\sigma_{UL})_{max} - (\sigma_{UL})_{min} = m(L)$ *(linear relationship)*

$$m := \frac{(\sigma_{UL})_{max} - (\sigma_{UL})_{min}}{L} = \begin{bmatrix} 0.0198 \\ 0.026 \end{bmatrix} \frac{ksf}{ft}$$

(linear relationship)

$$(\sigma_{UL})_{max.toe} := \overrightarrow{(m \cdot TWIDTH) + (\sigma_{UL})_{min}} = \begin{bmatrix} 0.525 \\ 0.596 \end{bmatrix} ksf$$

(uplift pressure at the connection of the toe to the foundation)

$$UL_{toe} := \frac{-TWIDTH \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)}{2} = \begin{bmatrix} -2.8 \\ -3.1 \end{bmatrix} klf$$

(uplift pressure resultant for the toe of the foundation)

$$(x_{UL})_{toe} := TWIDTH - \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{UL})_{max.toe}\right) + (\sigma_{UL})_{min}\right)}{3 \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)} = \begin{bmatrix} 2.9 \\ 2.8 \end{bmatrix} ft$$

(distance from the connection of the toe to the resultant of the uplift pressure)

Load Combinations

Resisting Side Forces - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \left(D + EV_r + Hs_r + SP_{toe} + UL_{toe}\right) = \begin{bmatrix} -9.2 \\ -9.4 \end{bmatrix} klf$$

(load case 1 for infrequent flooding)

$$\Sigma F_{toe} := \max\left(\overrightarrow{|LC1|}\right) = 9.4\ klf$$

(maximum of the drained vs undrained cases)

Factored Shear on Toe at Face of Stem

$$(V_u)_{toe} := \Sigma F_{toe} = 9.4\ klf$$

(maximum factored shear in toe)

Resultant Moment - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(D \cdot (x_D)_{toe}\right) + \left(\overrightarrow{Hs_r \cdot (x_{Hs})_r}\right) \\ + \left(\overrightarrow{EV_r \cdot (x_{EV})_r}\right) + \left(\overrightarrow{SP_{toe} \cdot (x_{SP})_{toe}}\right) \\ + \left(\overrightarrow{UL_{toe} \cdot (x_{UL})_{toe}}\right) \end{pmatrix} = \begin{bmatrix} -29.7 \\ -30.6 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case 1 for infrequent flooding)

Maximum Factored Moment in Toe at Face of Stem

$Mu_{toe} := \max(LC1) \cdot 1\ ft = -29.7\ kip \cdot ft$ *(resultant moment at base of floodwall stem per foot of wall)*

$Mu_{toe} := -Mu_{toe}$

Toe Reinforcement

Bottom Bars - Main Steel

$(d_b)_{toe.bot} := \text{Bar Size: \#8} = 1\ in$ *(bottom bar size in toe)*

$s_{toe.bot} := 12\ in$ *(bottom bar spacing in toe)*

$c_{toe.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in toe)*

$(A_s)_{toe.bot} := \frac{0.25 \cdot \pi \cdot (d_b)_{toe.bot}^{\ 2} \cdot b}{s_{toe.bot}} = 0.785\ in^2$ *(area of steel for bottom reinforcement in toe)*

$d_{toe.bot} := TTOE - c_{toe.bot} - \left(0.5 \cdot (d_b)_{toe.bot}\right) = 19.5\ in$ *(depth to reinforcement bottom reinforcement in toe)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{toe.bot} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot \langle f'_c - 4000\ psi \rangle}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$a_{toe.bot} := \frac{(A_s)_{toe.bot} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{toe.bot}} = 0.6\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)*

$(\phi M_n)_{toe.bot} := \phi_b \cdot (A_s)_{toe.bot} \cdot (F_y)_{60} \cdot \left(d_{toe.bot} - \frac{a_{toe.bot}}{2}\right) = 67.8\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{toe} := Check\left(Mu_{toe}, (\phi M_n)_{toe.bot}\right) = [\text{"OK"} \quad 0.44]$ *(nominal flexural check)*

Minimum Required Steel for Flexure

Solve Constraints Values

$As_{req} := 1.5\ in^2$

$Mu_{toe} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$

$(As_{req})_{toe} := \text{find}\left(As_{req}\right) = 0.5\ in^2$ *(minimum required reinforcement for flexural strength)*

Minimum Required Steel per ACI

$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.785\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.8\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.785\ in^2$

$A_{s\_1.3} := (As_{req})_{toe} \cdot \frac{4}{3} = 0.6\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{toe.req} := \text{if } A_{s\_1.3} < (A_s)_{toe.bot} \ \| \ as \leftarrow (As_{req})_{toe} \ \text{else} \ \| \ as \leftarrow A_{s.min} = 0.472\ in^2$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{toe.bot} = 0.8\ in^2$ *(area of steel provided in the horizontal direction for the toe)*

$(Steel\_Check_{bot})_{toe} := Check\left((A_s)_{toe.req}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.6]$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.4\ in^2$

$(Steel\_Check_{bot.ts})_{toe} := Check\left((A_{s.min})_{temp}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.6]$

(check stem reinforcement to required t&s reinforcement)

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{toe.bot}}{\left(b \cdot d_{toe.bot}\right)} = 0.0034$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{toe} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.4]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{toe.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in toe)*

$s_{toe.lat} := 12\ in$ *(lateral bar spacing in toe)*

$c_{toe.lat} :=$ 4″ cover *(cover for lateral reinforcement in toe)*

$(A_s)_{toe.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{toe.lat}^{\ 2} \cdot 12\ in}{s_{toe.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in toe)*

$d_{toe.lat} := TTS - c_{toe.lat} - (d_b)_{toe.bot} - 0.5 \cdot (d_b)_{toe.lat} = 12.625\ in$ *(depth to reinforcement lateral reinforcement in toe)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot (TTOE \cdot b)}{2} = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.43\ in^2$

$(A_s)_{toe.lat} = 0.442\ in^2$ *(area of steel provided in the lateral direction for the toe, both faces)*

$(Steel\_Check_{Lat})_{toe} := Check\left(A_{s.req}, (A_s)_{toe.lat}\right) = [\text{"OK"} \quad 1]$ *(check toe reinforcement to required reinforcement)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{actual} := \frac{(A_s)_{toe.lat}}{\left(b \cdot d_{toe.bot}\right)} = 0.0019$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Lat})_{toe} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.2]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

SHEAR CHECK

$N_u := 0\ kip$ *(compressive axial force in toe of foundation, conservatively ignored for analysis)*

$A_g := TTOE \cdot b = 288\ in^2$ *(gross area of concrete section)*

$V_c := \left(\left(2 \cdot \sqrt{f'c}\right) \cdot psi + \frac{N_u}{6 \cdot A_g}\right) \cdot b \cdot d_{toe.bot} = 31.4\ kip$ *(shear strength in concrete, EM 1110-2-2104, Eq 5-1)*

$\phi_V V_n := \phi_V \cdot V_c = 23.5\ kip$ *(nominal shear strength in concrete, EM 1110-2-2104, Eq 5-1)*

$V_{toe} := \left|(V_u)_{toe} \cdot b\right| = 9.4\ kip$

$V_{toe.check} := Check\left(V_{toe}, \phi_V V_n\right) = [\text{“OK”} \quad 0.4]$

Toe - Bottom Reinforcement

$(d_b)_{toe.bot} = 1\ in$ *bars located at* $s_{toe.bot} = 12\ in$ *centers*

Toe - Lateral Reinforcement

$(d_b)_{toe.lat} = 0.75\ in$ *bars located at* $s_{toe.lat} = 12\ in$ *centers*

Toe - Top Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

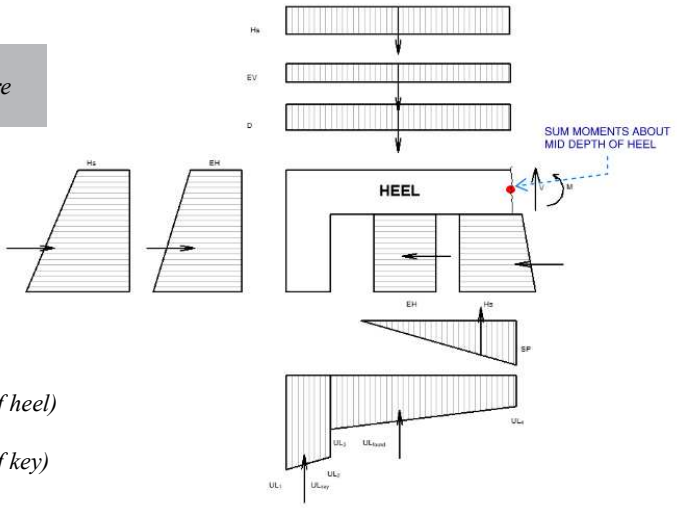
Toe - Top Lateral Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

HEEL DESIGN

Loads to Heel

Note: largest loading from drained and undrained cases used to create conservative design for loading. In each loading condition, drained loads are listed first and undrained last



$HWIDTH := BWIDTH - TTS - TWIDTH = 10.5\ ft$ *(Length of heel, includes key)*

Dead Load

$(\sigma_D)_{Heel} := \gamma_{conc} \cdot (TTOE) = 300\ psf$

$(\sigma_D)_{Key} := \gamma_{conc} \cdot (HK) = 525\ psf$

$D_{Heel} := (\sigma_D)_{Heel} \cdot HWIDTH = 3.2\ klf$ *(resultant dead load of heel)*

$D_{Key} := (\sigma_D)_{Key} \cdot TK = 1.1\ klf$ *(resultant dead load of key)*

$D := D_{Heel} + D_{Key} = 4.2\ klf$ *(resultant dead load of heel including key per linear foot of wall)*

$(x_{D.heel})_{heel} := \frac{HWIDTH}{2} = 5.3\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_{D.key})_{heel} := HWIDTH - \left(\frac{TK}{2}\right) = 9.5\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_D)_{heel} := \frac{D_{Heel} \cdot (x_{D.heel})_{heel} + D_{Key} \cdot (x_{D.key})_{heel}}{D_{Heel} + D_{Key}} = 6.3\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation including the key)*

Hydrostatic Loads - Top of Heel

Note: hydrostatic loads applied in three directions, notated as ah = above heel, fh = face of heel and bh = behind heel

$(\sigma_{Hs})_{ah} := \gamma_{water} \cdot HTS = 0.874\ ksf$ *(vertical water pressure from hydrostatic loading)*

$(Hs)_{ah} := (\sigma_{Hs})_{ah} \cdot HWIDTH = 9.2\ klf$ *(vertical water loading from hydrostatic loading)*

$(x_{Hs})_{ah} := \frac{HWIDTH}{2} = 5.25\ ft$ *(moment arm for vertical hydrostatic loading)*

Hydrostatic Loads - Face of Heel

$(\sigma_{Hs})_{fh.top} := \gamma_{water} \cdot HTS = 0.874\ ksf$ *(min horizontal hydrostatic loading, top of foundation)*

$(\sigma_{Hs})_{fh.bot} := \gamma_{water} \cdot (HTS + THEEL) = 1.217\ ksf$ *(min horizontal hydrostatic loading, bot of key)*

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(Hs)_{fh} := \frac{THEEL \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{2} = 5.7\ klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}\right) = 3.9\ ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} = \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(Hs)_{bh} := \frac{HK \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{2} = \begin{bmatrix} 3.6 \\ 4.2 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}\right) = \begin{bmatrix} 2.8 \\ 2.8 \end{bmatrix} ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Face of Heel

$(\sigma_{EH})_{fh.top} := \gamma'_{soil} \cdot k_0 \cdot HSD = 0.088\ ksf$ *(min horizontal soil loading, top of foundation)*

$(\sigma_{EH})_{fh.bot} := \gamma'_{soil} \cdot k_0 \cdot (HSD + THEEL) = 0.256\ ksf$ *(min horizontal soil loading, top of foundation)*

Note: conservatively the lateral earth pressure does not include the undrained case where the lateral soil pressure would be zero.

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(EH)_{fh} := \frac{THEEL \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{2} = 0.9\ klf$ *(resultant of the soil loading to the front face of heel)*

$(x_{EH})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{3 \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}\right) = 4.198\ ft$ *(moment arm for the soil loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.41 \\ 1.13 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bh.bot} = \begin{bmatrix} 1.41 \\ 1.13 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(EH)_{bh} := \frac{HK \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{2} = \begin{bmatrix} 4.9 \\ 4 \end{bmatrix} klf$ *(resultant of the horizontal soil loading to the back face of heel)*

Vertical Earth Pressures - Top of Heel

$(\sigma_{EV})_{ah} := \gamma'_{soil} \cdot HSD = 0.166\ ksf$ *(vertical buoyant soil pressure on heel)*

$(EV)_{ah} := (\sigma_{EV})_{ah} \cdot HWIDTH = 1.74\ klf$ *(vertical buoyant soil loading on heel)*

$(x_{EV})_{ah} := \frac{HWIDTH}{2} = 5.25\ ft$ *(moment arm for vertical soil loading)*

Soil Pressure Loading - Base of Heel

$L_0 := BWIDTH - BIC = \begin{bmatrix} 1.87 \\ 4.44 \end{bmatrix} ft$ *(length of base with no soil pressure loading, measured from front face of key back toward toe)*

$L := HWIDTH - L_0 = \begin{bmatrix} 8.63 \\ 6.06 \end{bmatrix} ft$ *(length of base with soil pressure loading, measured from beginning of pressure back toward connection)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{L}{(\sigma_{SP})_{heel}}$ *(similar triangles relationship between the total soil pressure load and the length of the base in compression to the length of the heel in compression to the maximum soil pressure loading at the connection)*

$(\sigma_{SP})_{heel} := \overrightarrow{-L \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} 0.75 \\ 0.64 \end{bmatrix} ksf$ *(maximum soil pressure loading at the connection of the heel)*

$SP_{heel} := \overrightarrow{0.5 \cdot (\sigma_{SP})_{heel} \cdot L} = \begin{bmatrix} 3.24 \\ 1.93 \end{bmatrix} klf$ *(resultant soil pressure loading on the heel)*

$(x_{SP})_{heel} := \frac{1}{3} L = \begin{bmatrix} 2.9 \\ 2 \end{bmatrix} ft$ *(moment arm for the soil pressure loading, measured from the connection of the heel)*

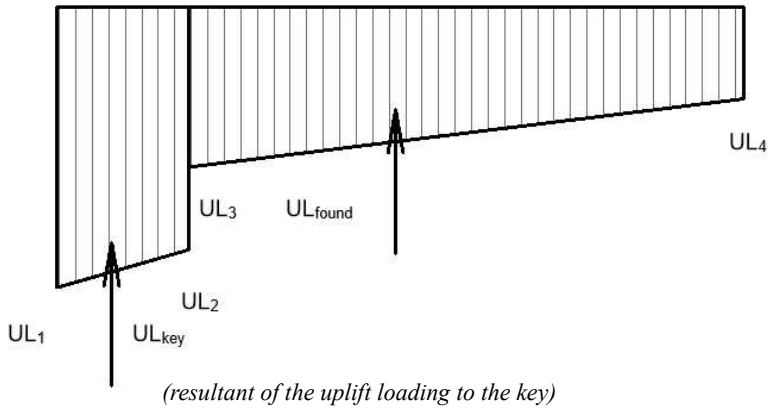
Uplifting Pressure

$UL_1 := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*



$UL_{key} := \frac{TK \cdot (UL_1 + UL_2)}{2} = \begin{bmatrix} 2.1 \\ 2.4 \end{bmatrix} klf$ *(resultant of the uplift loading to the key)*

$Heel\_Width := HWIDTH - TK = 8.5\ ft$ *(length of the heel; from the connection of the stem to the back face of the key)*

$(x_{UL})_{key} := Heel\_Width + \left(\frac{TK \cdot (2 \cdot UL_1 + UL_2)}{3 \cdot (UL_1 + UL_2)} \right) = \begin{bmatrix} 9.51 \\ 9.51 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

$m := \frac{(UL_4 - UL_3)}{BWIDTH - TK} = \begin{bmatrix} -0.0198 \\ -0.026 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship between the uplift pressure from the foundation behind the key)*

$UL_{stem} := m \cdot (HWIDTH - TK) + UL_3 = \begin{bmatrix} 0.6 \\ 0.6 \end{bmatrix} ksf$ *(uplift pressure at the stem)*

$UL_{found} := \frac{Heel\_Width \cdot (UL_3 + UL_{stem})}{2} = \begin{bmatrix} 5.4 \\ 6.3 \end{bmatrix} klf$ *(resultant of the uplift loading to the foundation; less the key)*

$(x_{UL})_{found} := \left(\frac{Heel\_Width \cdot (2 \cdot UL_3 + UL_{stem})}{3 \cdot (UL_3 + UL_{stem})} \right) = \begin{bmatrix} 4.44 \\ 4.46 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

Load Combinations

Note: Forces that are oriented to the left and up are considered negative forces and moments that would rotate the heel counterclockwise are positive for the purpose of summing forces and moments.

Forces on Heel - Horizontal Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left((EH)_{fh} - (EH)_{bh} \right) \\ + \left((Hs)_{fh} - (Hs)_{bh} \right) \end{pmatrix} = \begin{bmatrix} -2.9 \\ -2.3 \end{bmatrix} klf$ *(Summation of the forces in the horizontal direction note positive forces represent heel in compression)*

$(\Sigma F_{heelc})_{horz} := \max(LC1) = -2.3\ klf$

$(\Sigma F_{heel})_{horz} := \max\left(\overrightarrow{|LC1|}\right) = 2.9\ klf$ *(maximum of the drained vs undrained cases)*

$P\_Check :=$ if $(\Sigma F_{heelc})_{horz} > 0$
"Heel is in compression, conservatively ignore axial loads in moment capcacity check"
else
"Heel in tension, factored into moment capcacity check"

$P\_Check =$ "Heel in tension, factored into moment capcacity check"

$(\Sigma F_{heel})_{Tension} :=$ if $(\Sigma F_{heel})_{horz} > 0$ $= 0\ kip$
$0\ kip$
else
$|(\Sigma F_{heel})_{horz}| \cdot b$

Forces on Heel - Vertical Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} D + (EV)_{ah} + (Hs)_{ah} \\ + \left(UL_{key} + UL_{found}\right) + \left(SP_{heel}\right) \end{pmatrix} = \begin{bmatrix} 41.3 \\ 41.2 \end{bmatrix} klf$ *(summation of the forces in the vertical direction)*

$(\Sigma F_{heel})_{vert} := \max\left(LC1\right) = 41.3\ klf$ *(maximum of the drained vs undrained cases)*

Resultant Shear at Base

$Vu_{heel} := (\Sigma F_{heel})_{vert} = 41.3\ klf$ *(factored shear at connection of floodwall heel)*

Resultant Axial Load in Base

$(P_u)_{heel} := (\Sigma F_{heel})_{horz} = 2.9\ klf$ *(factored axial load at floodwall heel)*

$(\Sigma F_{heel})_{Tension} = 0\ ft \cdot klf$ *(tension in heel; from check above, zero if heel in compression)*

Note: Axial loads with positive values put the heel of the floodwall in compression and negative values put the heel of the floodwall in tension.

Resultant Moment - on Heel at Stem Face

$LC1_{pos} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{D \cdot (x_D)_{heel}}\right) \\ + \left(\overrightarrow{(EV)_{ah} \cdot (x_{EV})_{ah}}\right) + \left(\overrightarrow{(Hs)_{ah} \cdot (x_{Hs})_{ah}}\right) \\ + \left(\overrightarrow{(EH)_{fh} \cdot (x_{EH})_{fh}}\right) + \left(\overrightarrow{(Hs)_{fh} \cdot (x_{Hs})_{fh}}\right) \end{pmatrix} = 176.3\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{neg} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{(Hs)_{bh} \cdot (x_{Hs})_{bh}}\right) \\ + \left(\overrightarrow{(EH)_{bh} \cdot (x_{EH})_{bh}}\right) \\ + \left(\overrightarrow{SP_{heel} \cdot (x_{SP})_{heel}}\right) \\ + \left(\overrightarrow{UL_{key} \cdot (x_{UL})_{key}}\right) \\ + \left(\overrightarrow{UL_{found} \cdot (x_{UL})_{found}}\right) \end{pmatrix} = \begin{bmatrix} 122.4 \\ 123.5 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$\Sigma LC := \max\left(LC1_{pos} - LC1_{neg}\right) = 53.98\ kip$

$Mu_{heel} := \max\left(LC1_{pos} - LC1_{neg}\right) \cdot b = 54\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

Note: since section is under tension and flexure, heel to be designed per section B-4 of EM 1110-2-2104.

Heel Reinforcement

$Mu_{heel} = 54\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

$(P_u)_{heel} = 2.9\ \frac{kip}{ft}$ *(maximum factored axial tension at base of floodwall stem on the heel)*

$Vu_{heel} = 41.3\ \frac{kip}{ft}$ *(maximum factored shear at base of floodwall stem on the heel)*

Top Bars - Main Steel

$(d_b)_{heel.top} :=$ Bar Size: #8 $= 1\ in$ *(top bar size in heel)*

$(d_b)_{heel.bot} :=$ Bar Size: #8 $= 1\ in$ *(bottom bar size in heel)*

$s_{heel.top} := 8\ in$ *(top bar spacing in heel)*

$s_{heel.bot} := 12\ in$ *(bottom bar spacing in heel)*

$c_{heel.top} := 3''\ \text{cover}$ *(cover for top reinforcement in heel)*

$c_{heel.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in heel)*

$$(A_s)_{heel.top} := \frac{0.25 \cdot \pi \cdot (d_b)_{heel.top}^{\ 2} \cdot 12\ in}{s_{heel.top}} = 1.178\ in^2$$ *(area of steel for top reinforcement in heel)*

$$(A_s)_{heel.bot} := \frac{0.25 \cdot \pi \cdot (d_b)_{heel.bot}^{\ 2} \cdot 12\ in}{s_{heel.bot}} = 0.785\ in^2$$ *(area of steel for top reinforcement in heel)*

$$\rho := \frac{(A_s)_{heel.top}}{b \cdot TTOE} = 0.004$$ *(reinforcement ratio for primary tension steel)*

$$\rho' := \frac{(A_s)_{heel.bot}}{b \cdot TTOE} = 0.003$$ *(reinforcement ratio for bottom tension steel)*

$$d_{heel.top} := TTOE - c_{heel.top} - 0.5 \cdot (d_b)_{heel.top} = 20.5\ in$$ *(depth to top reinforcement in heel)*

$$a \cdot 0.85 \cdot f'c \cdot (d_b)_{heel.top} = (A_s)_{heel.top} \cdot f_y$$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\dfrac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$$a_{heel.top} := \frac{(A_s)_{heel.top} \cdot (F_y)_{60} + (P_u)_{heel} \cdot b}{0.85 \cdot f'_c \cdot d_{heel.top}} = 0.94\ in$$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1)*

Axial Strength Check

$$Pn_{max} := \left((A_s)_{heel.top} \cdot (F_y)_{60} + (A_s)_{heel.bot} \cdot (F_y)_{60}\right) = 117.8\ kip$$ *(design axial strength, EM 1110-2-2104, Eq B-44)*

$$\phi Pn := \phi_A \cdot Pn_{max} = 106\ kip$$

$$AxialCheck := Check\left((\Sigma F_{heel})_{horz} \cdot b, \phi Pn\right) = [\text{“OK”}\ \ 0.03]$$ *(tensile)*

Flexural Check

$$\phi M_{n.Heel} := \phi_b \cdot \left(0.85 \cdot f'_c \cdot a_{heel.top} \cdot b \cdot \left(d_{heel.top} - \frac{a_{heel.top}}{2}\right) - (P_u)_{heel} \cdot \left(d_{heel.top} - \frac{TTOE}{2}\right) \cdot b\right) = 62.9\ kip \cdot ft$$

(moment capacity for beam in flexure and axial tension, EM 2104, Eq D-1)

$$(M_{Flex\_Axial})_{Heel} := Check\left(Mu_{heel}, \phi M_{n.Heel}\right) = [\text{“OK”}\ \ 0.9]$$

Minimum Required Steel for Flexure

Guess Values

$$As_{req} := 1.5\ in^2$$

Constraints

$$Mu_{heel} = \phi_b \cdot \left(\left(As_{req} \cdot (F_y)_{60} \cdot \left(d_{heel.top} - \frac{\dfrac{As_{req} \cdot (F_y)_{60} + (P_u)_{heel} \cdot b}{0.85 \cdot f'_c \cdot d_{heel.top}}}{2}\right)\right) - \left((P_u)_{heel} \cdot \left(d_{heel.top} - \frac{TTOE}{2}\right) \cdot b\right)\right)$$

Solver

$$As_{req.stem} := \mathbf{find}\left(\mathbf{As_{req}}\right) = 0.613\ in^2$$

(minimum steel required for flexural strength)

$(A_{s.min})_{heel.top} := As_{req.stem} = 0.6\ in^2$

Minimum Required Steel per ACI

$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.825\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.82\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

temperature and shrinkage reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b, (A_{s.min})_{temp}\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.825\ in^2$

$A_{s\_1.3} := (A_{s.min})_{heel.top} \cdot \frac{4}{3} = 0.8\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{heel.req} := \text{if } A_{s\_1.3} < (A_s)_{heel.top} \parallel as \leftarrow (A_{s.min})_{heel.top}$ else $\parallel as \leftarrow A_{s.min} = 0.613\ in^2$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{heel.top} = 1.2\ in^2$ *(area of steel provided in the horizontal direction for the heel)*

$(Steel\_Check_{Top})_{heel} := Check\left((A_s)_{heel.req}, (A_s)_{heel.top}\right) = [\text{"OK"} \quad 0.52]$ *(check stem reinforcement to required reinforcement)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{actual} := \frac{(A_s)_{heel.top}}{\left(b \cdot d_{heel.top}\right)} = 0.0048$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{top})_{heel} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Note: Current version of EM 1110-2-2104 provides this limit as a guidance. This is ok

Lateral Bars

$(d_b)_{heel.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in heel)*

$s_{heel.lat} := 12\ in$ *(lateral bar spacing in heel)*

$c_{heel.lat} :=$ 4″ cover *(cover for lateral reinforcement in heel)*

$(A_s)_{heel.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{heel.lat}^2 \cdot 12\ in}{s_{heel.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in heel)*

$(\rho\_check_{lat})_{heel} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.5]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Heel - Top Reinforcement

$(d_b)_{heel.top} = 1\ in$ *bars located at* $s_{heel.top} = 8\ in$ *centers*

Heel - Lateral Reinforcement

$(d_b)_{heel.lat} = 0.75\ in$ *bars located at* $s_{heel.lat} = 12\ in$ *centers*

Heel - Bottom Reinforcement

Reference above calculations for the bottom steel from the toe design, toe steel is transferred through the base into the heel.

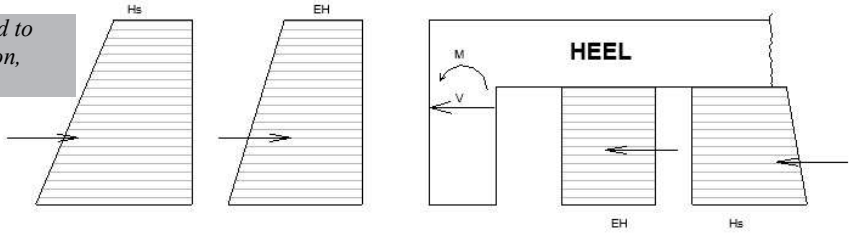
Heel - Bottom Lateral Reinforcement

Reference above calculations for the bottom steel from the toe design, toe steel is transferred through the base into the heel.

KEY DESIGN

Loads to Key

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



$HK = 3.5\ ft$ *(depth of key, from bottom of foundation down)*

$THEEL = 5.5\ ft$ *(depth of key, from top of foundation down)*

Hydrostatic Loads - Front of Key

Note: hydrostatic loads applied in two directions, notated as fk = front of key and bk = back of key

$(\sigma_{Hs})_{fk1} := \gamma_{water} \cdot (HTS + TTOE) = 0.998\ ksf$ *(horizontal water loading, top of key)*

$(\sigma_{Hs})_{fk2} := \gamma_{water} \cdot (HTS + THEEL) = 1.217\ ksf$ *(horizontal water loading, bottom of key)*

$(Hs)_{fk} := \frac{HK \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})}{2} = 3.9\ klf$ *(hydrostatic loading to the front of key)*

$(x_{Hs})_{fk} := \frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{fk2}) + (\sigma_{Hs})_{fk1})}{3 \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})} = 1.81\ ft$ *(moment arm for hydrostatic loading, measured down from key connection to foundation)*

Hydrostatic Loads - Back of key

$(\sigma_{Hs})_{bk.top} := (\sigma_{Hs})_{bh.top} = \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bk.bot} := (\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(Hs)_{bk} := \frac{HK \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{2} = \begin{bmatrix} 3.6 \\ 4.2 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of the key)*

$(x_{Hs})_{bk} := \left(\frac{HK \cdot (2 \cdot (\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{3 \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})} \right) = \begin{bmatrix} 1.8 \\ 1.8 \end{bmatrix} ft$ *(moment arm of the hydrostatic loading to the front face of the key, measured down from the connection to foundation)*

Lateral Earth Pressures - Face of Key

$(\sigma_{EH})_{fk.top} := \gamma'_{soil} \cdot k_0 \cdot (HTS + TTOE) = 0.489\ ksf$ *(min horizontal lateral earth loading, top of foundation)*

$(\sigma_{EH})_{fk.bot} := \gamma'_{soil} \cdot k_0 \cdot (HTS + THEEL) = 0.596\ ksf$ *(min horizontal lateral earth loading, bottom of foundation)*

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(EH)_{fk} := \frac{HK \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{2} = 1.9\ klf$ *(resultant of the lateral earth loading to the front face of key)*

$(x_{EH})_{fk} := \frac{HK \cdot (2 \cdot (\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{3 \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})} = 1.808\ ft$ *(moment arm of the lateral earth loading to to the front face of the key, measured from the the connection of the key to the foundation)*

Lateral Earth Pressures - Back of Key

$(\sigma_{EH})_{bk.top} := (\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.41 \\ 1.13 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

Resultant Moment - on Toe

$LC1_{fk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{fk} \cdot (x_{EH})_{fk}}\right) + \left(\overrightarrow{(Hs)_{fk} \cdot (x_{Hs})_{fk}}\right)\right) = 16.7\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{bk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{bk} \cdot (x_{EH})_{bk}}\right) + \left(\overrightarrow{(Hs)_{bk} \cdot (x_{Hs})_{bk}}\right)\right) = \begin{bmatrix} 24 \\ 22.8 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$LC1_{key} := LC1_{bk} - LC1_{fk} = \begin{bmatrix} 7.3 \\ 6.1 \end{bmatrix} \frac{kip \cdot ft}{ft}$

$Mu_{key} := \max\left(LC1_{bk} - LC1_{fk}\right) \cdot 1\ ft = 7.3\ kip \cdot ft$ *(factored maximum moment at connection of floodwall key to the heel)*

Key Reinforcement

Back Bars - Main Steel

$(d_b)_{key.main} :=$ Bar Size: #8 $= 1\ in$ *(main bar size in key)*

$s_{key.main} := 12\ in$ *(main bar spacing in key)*

$c_{key.main} :=$ 4″ cover *(cover for main reinforcement in key)*

$(A_s)_{key.main} := \frac{0.25 \cdot \pi \cdot (d_b)_{key.main}^{\ 2} \cdot 12\ in}{s_{key.main}} = 0.785\ in^2$ *(area of steel for top reinforcement in key)*

$d_{key.main} := TTOE - c_{key.main} - 0.5 \cdot (d_b)_{key.main} = 19.5\ in$ *(depth to main reinforcement in key)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{key.main} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot \left(f'_c - 4000\ psi\right)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.8$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{key.main} := \frac{(A_s)_{key.main} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{key.main}} = 0.6\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1)*

$(\phi M_n)_{key.main} := \phi_b \cdot (A_s)_{key.main} \cdot (F_y)_{60} \cdot \left(d_{key.main} - \frac{a_{key.main}}{2}\right) = 67.8\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{key} := Check\left(Mu_{key}, (\phi M_n)_{key.main}\right) = [\text{“OK”} \quad 0.11]$ *(nominal flexural check, utilization ratio)*

Minimum Required Steel for Flexure

Given Values

$As_{req} := 1.5\ in^2$

Constraints

$Mu_{key} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{key.main} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{key.main}} \right)$

Solve

$As_{req.stem} := \mathbf{find}\left(\mathbf{As_{req}}\right) = 0.083\ in^2$

$(A_{s.min})_{key.min} := As_{req.stem} = 0.1\ in^2$

Minimum Required Steel per ACI

$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{key.main} = 0.8\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{key.main} = 0.8\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.003 \cdot \left(\frac{TK \cdot b}{2} \right) = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b \right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.785\ in^2$

$A_{s\_1.3} := (A_{s.min})_{key.min} \cdot \frac{4}{3} = 0.1\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{key.req} := \text{if } A_{s\_1.3} < (A_s)_{key.main} \ \| \ as \leftarrow (A_{s.min})_{key.min} \ \text{else} \ \| \ as \leftarrow A_{s.min} = 0.083\ in^2$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{key.main} = 0.8\ in^2$ *(area of steel provided in the horizontal direction for the heel)*

$(Steel\_Check_{Top})_{key} := Check\left((A_s)_{key.req}, (A_s)_{key.main} \right) = [\text{“OK”} \quad 0.1]$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Requirements

$(A_{s.min})_{temp} = 0.4\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Top.ts})_{key} := Check\left((A_{s.min})_{temp}, (A_s)_{key.main} \right) = [\text{“OK”} \quad 0.6]$

(temperature and shrinkage steel of key, check utilization ratio)

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}} \right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1} \right)} \right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{actual} := \frac{(A_s)_{key.main}}{\left(b \cdot d_{key.main} \right)} = 0.0034$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{main})_{key} := Check\left(\rho_{actual}, \rho_{max} \right) = [\text{“OK”} \quad 0.4]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{key.lat} := \text{Bar Size: \#6} = 0.75\ in$ *(lateral bar size in key)*

$s_{key.lat} := 12\ in$ *(lateral bar spacing in key)*

$c_{key.lat} := 4''\ \text{cover}$ *(cover for lateral reinforcement in key)*

$(A_s)_{key.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{key.lat}^{\ 2} \cdot 12\ in}{s_{key.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in key)*

$d_{key.lat} := TK - c_{key.lat} - (d_b)_{key.main} - 0.5 \cdot (d_b)_{key.lat} = 18.6\ in$ *(depth to reinforcement lateral reinforcement in key)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot (TK \cdot b)}{2} = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.4\ in^2$

$(A_s)_{key.lat} := (A_s)_{key.lat} \cdot 2 = 0.9\ in^2$ *(area of steel provided in the lateral direction for the key, both faces)*

$(Steel\_Check_{Lat})_{key} := Check\left(A_{s.req}, (A_s)_{key.lat}\right) = [\text{"OK"} \quad 0.5]$

(check key reinforcement to required reinforcement)

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{actual} := \frac{(A_s)_{key.lat}}{(b \cdot d_{key.main})} = 0.0038$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{lat})_{key} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.5]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

12 FT T-Wall Load Cases and Strength Design

Upper Turkey Creek

Merriam, KS

ASSUMPTIONS

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

FLOOD LOAD CASES

Unusual Case

Top of Wall, ACE = 100 year event, Unusual Case

WSE = Top of Protection

Usual Case

ACE = 10 year event, Usual Case

WSE elevation below the top of the foundation

Note: The Unusual Flood Case with water to the top of the wall governs the design of this floodwall. Non-flood condition loads such as construction, seismic and wind are addressed in the stem design; however, it is apparent that the top of wall flood condition governs stability and the primary steel design so only the Unusual top of wall flood load is considered for stability and the base design.

The Usual Flood Case does not have water to the top of the foundation and is not included in these calculations.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$\gamma'_{soil} := \gamma_{soil} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$q_n := 2000\ psi$ *(bearing pressure, Reference DDR Table 9.2)*

Drained Soil Conditions

$\phi_{drained} := 28\ deg$ *(internal friction angle for drained soil condition)*

$C_{drained} := 0\ psf$ *(cohesion for drained soil condition)*

$k_0 := 1 - \sin\left(\phi_{drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

Undrained Soil Conditions

$\phi_{undrained} := 0\ deg$ *(internal friction angle for drained soil condition)*

$C_{undrained} := 1000\ psf$ *(cohesion for drained soil condition)*

$(k_0)_{undrained} := 1 - \sin\left(\phi_{undrained}\right) = 1$ *(at-rest soil pressure coefficient for the undrained condition)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(young's modulus of elasticity for steel)*

$(F_y)_{30} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$(F_y)_{60} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$\varepsilon_{ty} := \frac{(F_y)_{60}}{E_{steel}} = 0.0021$ *(yield strain of 60 ksi steel)*

Concrete Properties

$f'_c := 4500\ psi$ *(concrete compressive strength for all structures)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength for all structures)*

$q\lambda_c := 1.0$ *(concrete modification factor)*

$cover_3 := 3\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$cover_4 := 4\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$\gamma_{conc} := 150\ pcf$ *(concrete unit weight)*

$Ec := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$ *(young's modulus of elasticity for concrete)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

Load Factors

Serviceability Load Factors

Note: the unusual loading condition is used for the top of the floodwalls since they are designed to the 100 year event. the usual loading condition is defined as the 10 year event.

$(\gamma_p)_{Serve.u} := 2.2$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

$(\gamma_p)_{Serve.n} := 1.6$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

Strength Limit States

$\phi_b := 0.9$ *(bending load reduction factor - ACI 318-19 21.2.2, Table 21.2.2)*

$\phi_A := 0.9$

$\phi_V := 0.75$ *(shear load reduction factor - ACI 318-19 Table 21.2.1)*

CT WALL DATA

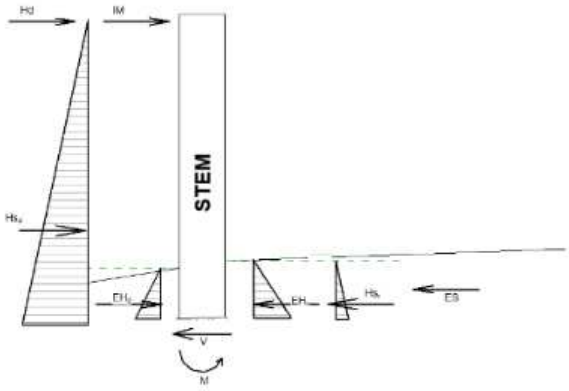
STEM DESIGN, RIVER SIDE

Loads to Stem

Note: largest loading from drained and undrained cases used to determine the controlling load case. In each loading condition, drained loads are listed first and undrained last.

This design for the riverside steel, along with the EnerCalc calculations, attached will be used for the landside steel design for simplicity. By inspection, the riverside reinforcement is sufficient for the landside reinforcement design.



Hydrostatic Loads

$\sigma_{Hsd} := \begin{bmatrix} \gamma_{water} \cdot HTS \\ \gamma_{water} \cdot HTS \end{bmatrix} = \begin{bmatrix} 748.8 \\ 748.8 \end{bmatrix} psf$ *(hydrostatic pressure loading to driving side)*

$Hs_d := \overrightarrow{0.5 \cdot \sigma_{Hsd} \cdot HTS} = \begin{bmatrix} 4.493 \\ 4.493 \end{bmatrix} klf$ *(hydrostatic loading to driving side)*

$(x_{Hs})_d := HTS \cdot \frac{1}{3} = 4\ ft$ *(moment arm for hydrostatic loading to the driving side from the base of the stem)*

Note: assume that hydrostatic loading from the resisting side of the T-wall provided from groundwater up to the ground surface. Assume that all additional water from the resisting side, landside, of the floodwall is conveyed away through interior drainage systems.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 156 \\ 156 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{0.5 \cdot \sigma_{Hsr} \cdot HSR} = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} klf$ *(hydrostatic loading to resisting side)*

$(x_{Hs})_r := HSR \cdot \frac{1}{3} = 0.83\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Lateral Earth Loading

$(\sigma_{EHd})_{stem} := \sigma_{EHd} \cdot \left(\frac{HSD}{HSD + THEEL} \right) = \begin{bmatrix} 0.096 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side of stem)*

$EH_d := \overrightarrow{0.5 \cdot (\sigma_{EHd})_{stem} \cdot HSD} = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to driving side of stem)*

$(x_{EH})_d := HSD \cdot \frac{1}{3} = 0.8\ ft$ *(moment arm for lateral earth loading to the driving side from the base of the stem)*

$(\sigma_{EHr})_{stem} := \sigma_{EHr} \cdot \frac{HSR}{HSR + TTOE} = \begin{bmatrix} 0.12 \\ 0.207 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side of stem)*

$EH_r := \overrightarrow{0.5 \cdot (\sigma_{EHr})_{stem} \cdot HSR} = \begin{bmatrix} 0.2 \\ 0.3 \end{bmatrix} klf$ *(lateral earth loading to resisting side of stem)*

$(x_{EH})_r := HSR \cdot \frac{1}{3} = 0.8\ ft$ *(moment arm for lateral earth loading to the resisting side from the base of the stem)*

Impact Loading

Note: reference DDR for discussion of impact loading on floodwalls.

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

$(x_{IM})_d := HTS = 12\ ft$ *(moment arm of the impact load from the base of the stem)*

Operating Equipment

$p_{const} := 250\ psf$ *(construction surcharge loading)*

Note: assume that the surcharge loading is uniform and that the resultant is mid-height of the soil depth.

$d_{soil} := HSR = 2.5\ ft$ *(depth of soil cover on stem)*

$(x_Q)_d := \frac{HSR}{2} = 1.3\ ft$ *(resultant height above base of stem)*

$x_Q := d_{soil} - (x_Q)_d = 1.3\ ft$ *(depth from resultant to top of soil)*

$\sigma_H := p_{const} \cdot k_0 = 0.133\ ksf$ *(lateral linear pressure applied to wall)*

$Q := \sigma_H \cdot HSR = 0.332\ klf$ *(lateral surcharge load to structure, usual case)*

Wind

Note: for conservative analysis, wind loading only applied to the driving side as a positive pressure or applied to the resisting side as a negative pressure.

$(p_w)_p := 30.4\ psf$ *(primary wind pressure, reference DDR)*

$(p_w)_c := 15.8\ psf$ *(companion wind pressure, reference DDR)*

$G := 0.85\ \frac{1}{ft}$ *(gust factor, ASCE 7-16 Section 26.11.1)*

$C_f := 1.3$ *(force coefficient from ASCE 7-16, figure 29.3-1, s/h = 1 and B/s = '>45')*

$d := HTS - HSR = 9.5\ ft$ *(exposed surface of the stem for wind pressure)*

$A_s := 1\ ft \cdot d = 9.5\ ft^2$ *(exposed surface area of the wall per linear foot)*

$W_c := (p_w)_c \cdot G \cdot C_f \cdot A_s = 0.166\ klf$ *(wind loading, usual case for companion loading)*

$W_p := (p_w)_p \cdot G \cdot C_f \cdot A_s = 0.319\ klf$ *(wind loading, unusual case)*

$(x_W)_d := HTS - \frac{d}{2} = 7.3\ ft$ *(resultant height above base of stem)*

Earthquake Loading: Equivalent Lateral Force

$D_{wall} := (TTS \cdot HTS) \cdot \gamma_{conc} = 2.7\ \frac{1}{ft} \cdot kip$ *(dead load of the stem of the wall)*

$I_e := 1.5$ *(importance factor, ASCE 7-16 Table 1.5-2)*

$R := 2.5$ *(response modification factor, ASCE 7-16, Table 12.2-1, Item G.3)*

$S_{DS} := 0.101$ *(seismic spectral acceleration for short period)*

$Cs := \frac{S_{DS}}{\frac{R}{I_e}} = 0.1$ *(seismic response coefficient, ASCE 7-16 12.8-2)*

$V := Cs \cdot D_{wall} = 0.2\ klf$ *(seismic base shear, ASCE 7-16, EQ 12.8-1)*

$EQ := V = 0.2\ klf$

$(x_{EQ}) := HSR = 2.5\ ft$ *(resultant height above base of stem)*

Load Combinations

Note: Usual design cases not considered here as the Usual pool level does not reach the base of the stem.

Driving Side Forces

$LC1_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Hs_d + IM) = \begin{bmatrix} 7.5 \\ 7.3 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot (EH_d + EQ) = \begin{bmatrix} 0.5 \\ 0.3 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Q) = \begin{bmatrix} 0.7 \\ 0.5 \end{bmatrix} klf$ *(load case 3 for construction)*

Resisting Side Forces

$LC1_r := (\gamma_p)_{Serve.n} \cdot (EH_r + Hs_r - W_c) = \begin{bmatrix} 0.3 \\ 0.5 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.2 \\ 0.4 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.2 \\ 0.4 \end{bmatrix} klf$ *(load case 4 for construction)*

Resultant Shear at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 7.3 \\ 6.9 \end{bmatrix} klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.2 \\ -0.2 \end{bmatrix} klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.5 \\ 0.1 \end{bmatrix} klf$ *(equilibrium load case 3)*

$\Sigma F_{stem} := \text{stack}(LC1, LC2, LC3)$

Note: Maximum factored shear loading to the stem is the governing loading for the river side steel design. Minimum factored shear loading is the governing landside steel design.

$(Vu)_{stem} := \max(\Sigma F_{stem}) = 7.3\ klf$ *(resultant factored shear at base of floodwall stem, driving side)*

Resultant Moment - Driving Side

$LC1_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Hs_d \cdot (x_{Hs})_d \right) + IM \cdot (x_{IM})_d \right) = \begin{bmatrix} 30.8 \\ 30.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(EQ \cdot (x_{EQ}) \right) \right) = \begin{bmatrix} 0.8 \\ 0.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Q \cdot \left((x_Q)_d \right) \right) \right) = \begin{bmatrix} 0.8 \\ 0.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction)*

Resultant Moment - Resisting Side

$LC1_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) + \left(Hs_r \cdot (x_{Hs})_r \right) \right) = \begin{bmatrix} 0.5 \\ 0.6 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum flooding)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0.2 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0.2 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction or surcharge loading)*

Resultant Moment at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 30.4 \\ 30.1 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.6 \\ 0.3 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.6 \\ 0.3 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 3)*

$\Sigma M_{stem} := \text{stack}(LC1, LC2, LC3)$ *(resultant factored moment at base of floodwall stem)*

$(Mu)_{stem} := \max(\Sigma M_{stem}) \cdot 1\ ft = 30.4\ kip \cdot ft$ *(resultant moment at base of floodwall stem, riverside steel design)*

Design Check Function

(system check for capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing arrays)

$Check_v(X_U, X_N) :=$
- for $i \in$ **ORIGIN** .. last(X_U)
  - if $X_{U_i} > X_{N_i}$
    - $ch_{i,1} \leftarrow$ "NO GOOD"
    - $ch_{i,2} \leftarrow \frac{X_{U_i}}{X_{N_i}}$
  - else if $X_{N_i} = 0$ *(if the capacity is zero, used for error handling)*
    - $ch_{i,1} \leftarrow$ "N/A"
  - else *(if the required is less than the capacity)*
    - $ch_{i,1} \leftarrow$ "OK"
    - $ch_{i,2} \leftarrow \frac{X_{U_i}}{X_{N_i}}$
- ch

(user defined function to check the design capacity against the required capacity, function for use with comparing scalar values)

$Check(X_U, X_N) :=$
- if $X_U > X_N$
  - $ch_{1,1} \leftarrow$ "NO GOOD"
  - $ch_{1,2} \leftarrow \frac{X_U}{X_N}$
- else if $X_U = 0$ *(if the capacity is zero, used for error handling)*
  - $ch_{1,1} \leftarrow$ "N/A"
- else *(if the required is less than the capacity)*
  - $ch_{1,1} \leftarrow$ "OK"
  - $ch_{1,2} \leftarrow \frac{X_U}{X_N}$
- ch

(if the required is greater than the capacity)

$b := 12\ in$ *(strip width for analysis)*

Stem Reinforcement

Vertical Bars

$(d_b)_{stem.vert} :=$ Bar Size: #8 $= 1\ in$ *(vertical bar size in stem)*

$s_{stem.vert} := 12\ in$ *(vertical bar spacing in stem)*

$c_{stem.vert} :=$ 3″ cover *(cover for vertical reinforcement in stem)*

$(A_s)_{stem.vert} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.vert}^{\ 2} \cdot b}{s_{stem.vert}} = 0.785\ in^2$ *(area of steel vertical reinforcement in stem)*

$d_{stem.vert} := TTS - c_{stem.vert} - \left(0.5 \cdot (d_b)_{stem.vert}\right) = 14.5\ in$ *(depth to reinforcement vertical reinforcement in stem)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{stem} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$$a_{stem.vert} := \frac{(A_s)_{stem.vert} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}} = 0.85\ in$$

(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)

$$(\phi M_n)_{stem.vert} := \phi_b \cdot (A_s)_{stem.vert} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{a_{stem.vert}}{2}\right) = 49.7\ kip \cdot ft$$

(nominal flexural strength, EM1110-2-2104, B-49)

$$(Flex_{nom})_{Stem} := Check\left((Mu)_{stem}, (\phi M_n)_{stem.vert}\right) = [\text{"OK"} \quad 0.61]$$

(nominal flexural check, with Utilization ratio)

Minimum Required Steel for Flexure

Solve Constraints Given Values

$$As_{req} := 1.5\ in^2$$

$$(Mu)_{stem} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$$

$$As_{req.stem} := \mathbf{find}\left(\mathbf{As_{req}}\right) = 0.483\ in^2$$

$$(A_{s.min})_{stem.ten} := As_{req.stem} = 0.483\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.584\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.58\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTS \cdot b) = 0.324\ in^2$$

(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$

(minimum area of steel required for flexural capacity)

$$A_{s.min} = 0.584\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{stem.ten} \cdot \frac{4}{3} = 0.644\ in^2$$

(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)

$$(A_s)_{stem.req} := \begin{cases} as \leftarrow (A_{s.min})_{stem.ten} & \text{if } A_{s\_1.3} < (A_s)_{stem.vert} \\ as \leftarrow A_{s.min} & \text{else} \end{cases} = 0.483\ in^2$$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{stem.vert} = 0.8\ in^2$$

(area of steel provided in the vertical direction for the stem)

$$(Steel\_Check_{Vert})_{Stem} := Check\left((A_s)_{stem.req}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.6]$$

(check stem reinforcement to required reinforcement)

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Vert.ts})_{Stem} := Check\left((A_{s.min})_{temp}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$ *(check stem reinforcement to temperature and shrinkage requirements)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{stem.vert}}{\left(b \cdot d_{stem.vert}\right)} = 0.0045$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{Stem} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{stem.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in stem)*

$s_{stem.lat} := 12\ in$ *(lateral bar spacing in stem)*

$(A_s)_{stem.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.lat}^{\ 2} \cdot 12\ in}{s_{stem.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in stem)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot \left(TTS \cdot b\right)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.3\ in^2$

$(A_s)_{stem.lat} = 0.4\ in^2$ *(area of steel provided in the lateral direction for the stem)*

$(Steel\_Check_{Lat})_{Stem} := Check\left(A_{s.req}, (A_s)_{stem.lat}\right) = [\text{"OK"} \quad 0.7]$ *(check stem reinforcement to required reinforcement)*

Riverside Reinforcement

Primary Reinforcement

$(d_b)_{stem.vert} = 1\ in$ *bars located at* $s_{stem.vert} = 12\ in$ *centers*

Lateral Reinforcement

$(d_b)_{stem.lat} = 0.75\ in$ *bars located at* $s_{stem.lat} = 12\ in$ *centers*

Deflection Check

Note: Reference provided justification file for loading conditions and attached EnerCalc calculations for the deflections in floodwall stem since stem thickness is less than H/8. From EnerCalc report, wall deflections limited to H/6838, which is less than expected movement capacity in waterstop and wall joints. 12 ft tall floodwalls to have stems with above detailed reinforcement.

Landside Reinforcement

For design simplicity, landside reinforcement to match both primary and lateral reinforcement.

$s_{stem.vert2} := 12\ in$

$A_{vf} := \left(\frac{\pi}{4}\right) \cdot (d_b)_{stem.vert.2}{}^2 \cdot \left(\frac{b}{s_{stem.vert2}}\right) = 0.4\ in^2$

$V_n := \mu \cdot A_{vf} \cdot f_y = 26.5\ kip$ *(shear-friction strength, ACI 318-19, eq 22.9.4.2)*

Table 22.9.4.2—Coefficients of friction

Contact surface condition	Coefficient of friction μ[1]	
Concrete placed monolithically	1.4λ	(a)
Concrete placed against hardened concrete that is clean, free of laitance, and intentionally roughened to a full amplitude of approximately 1/4 in.	1.0λ	(b)
Concrete placed against hardened concrete that is clean, free of laitance, and not intentionally roughened	0.6λ	(c)
Concrete placed against as-rolled structural steel that is clean, free of paint, and with shear transferred across the contact surface by headed studs or by welded deformed bars or wires.	0.7λ	(d)

[1]λ = 1.0 for normalweight concrete. For lightweight concrete, λ is calculated as given in 19.2.4, but shall not exceed 0.85.

Table 22.9.4.4—Maximum V_n across the assumed shear plane

Condition	Maximum V_n		
Normalweight concrete placed monolithically or placed against hardened concrete intentionally roughened to a full amplitude of approximately 1/4 in.	Least of (a), (b), and (c)	$0.2f'_cA_c$	(a)
		$(480 + 0.08f'_c)A_c$	(b)
		$1600A_c$	(c)
Other cases	Lesser of (d) and (e)	$0.2f'_cA_c$	(d)
		$800A_c$	(e)

Maximum Shear Friction

$A_c := b \cdot TTS = 1.5\ ft^2$

$(V_n)_a := 0.2\ f'_c \cdot A_c = 194.4\ kip$ *(shear-friction maximum, equation a, Table 22.9.4.4)*

$(V_n)_b := \left(480\ psi + 0.08 \cdot f'_c\right) \cdot A_c = 181.4\ kip$ *(shear-friction maximum, equation b, Table 22.9.4.4)*

$(V_n)_c := \left(16000\ psi\right) A_c = 3456\ kip$ *(shear-friction maximum, equation c, Table 22.9.4.4)*

$(V_n)_{max} := \max\left((V_n)_a, (V_n)_b, (V_n)_c\right) = 3456\ kip$ *(shear-friction maximum, Table 22.9.4.4)*

Shear Strength

$\phi_V = 0.75$ *(reduction factor for shear capacity)*

$\phi_V V_n := \phi_V \cdot min\left((V_n)_{max}, V_n\right) = 19.9\ kip$ *(factored shear-friction strength)*

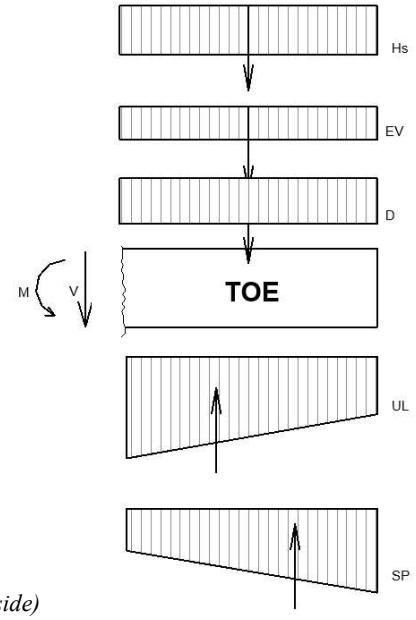
$V_{stem} := (Vu)_{stem} \cdot b = 7.3\ kip$ *(calculated shear required at base of stem)*

$V_{check} := Check\left(V_{stem}, \phi_V V_n\right) = [\text{“OK”} \quad 0.4]$ *(shear check, utilization ratio)*

Toe Check

Loads to Toe

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



Dead Load

$\sigma_D := \gamma_{conc} \cdot TTOE = 300\ psf$

$D := \sigma_D \cdot TWIDTH = 1.2\ klf$ *(resultant dead load of toe)*

$(x_D)_{toe} := \frac{TWIDTH}{2} = 2\ ft$ *(moment arm of the dead loading from the connection of the toe to the foundation)*

Hydrostatic Loads Above Toe

Note: Groundwater assumed to the soil surface. Potential additional seepage pressure conservatively ignored.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 156 \\ 156 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{TWIDTH \cdot \sigma_{Hsr}} = \begin{bmatrix} 0.6 \\ 0.6 \end{bmatrix} klf$ *(Resultant hydrostatic loading to resisting side)*

$(x_{Hs})_r := TWIDTH \cdot 0.5 = 2\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Vertical Earth Pressure

$\sigma_{EV} := \gamma'_{soil} \cdot HSR = 144\ psf$

$EV_r := \begin{bmatrix} \sigma_{EV} \cdot TWIDTH \\ \sigma_{EV} \cdot TWIDTH \end{bmatrix} = \begin{bmatrix} 0.576 \\ 0.576 \end{bmatrix} klf$ *(buoyant force of vertical soil loading)*

$(x_{EV})_r := \frac{TWIDTH}{2} = 2\ ft$

Soil Pressure

$(\sigma_{SP})_{max} = \begin{bmatrix} -1.581 \\ -1.36 \end{bmatrix} ksf$ *(max soil loading from CT Wall Output)*

$BWIDTH = 12.5\ ft$ *(total length of base of wall)*

$BIC_{percent} := \begin{bmatrix} 89.61 \\ 75.35 \end{bmatrix}\%$ *(percent of the base in compression)*

$BIC := BWIDTH \cdot BIC_{percent} = \begin{bmatrix} 11.2 \\ 9.4 \end{bmatrix} ft$ *(length of base in compression)*

$TWIDTH = 4\ ft$ *(length of toe of the foundation)*

note: using the length of the toe to determine the soil loading at the the connection of the toe to the stem and heel, use similar triangles to determine the loading at the connection of the toe.

$NTWIDTH := BIC - TWIDTH = \begin{bmatrix} 7.2 \\ 5.4 \end{bmatrix} ft$ *(length of the not-toe of the foundation in compression)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{NTWIDTH}{(\sigma_{SP})_1}$ *(relationship of similar triangles)*

$(\sigma_{SP})_1 := \overrightarrow{NTWIDTH \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} -1.02 \\ -0.78 \end{bmatrix} ksf$ *(soil pressure loading at the connection of the toe)*

$SP_{toe} := \frac{TWIDTH \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)}{2} = \begin{bmatrix} -5.2 \\ -4.3 \end{bmatrix} klf$ *(resultant soil loading to the toe of the foundation)*

$(x_{SP})_{toe} := \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{SP})_{max}\right) + (\sigma_{SP})_1\right)}{3 \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)} = \begin{bmatrix} 2.1 \\ 2.2 \end{bmatrix} ft$ *(moment arm from the connection of the toe to the resultant of the soil pressure loading)*

Uplift Pressures

$(\sigma_{UL})_{min} = \begin{bmatrix} 0.578 \\ 0.614 \end{bmatrix} ksf$ *(minimum uplift pressure at the end of the toe)*

$(\sigma_{UL})_{max} = \begin{bmatrix} 0.7 \\ 0.775 \end{bmatrix} ksf$ *(maximum uplift pressure behind the key)*

Note: Uplift pressure drops off linearly from the back of the key to the toe of the foundation

$BWIDTH = 12.5\ ft$ *(foundation width)*

$TK = 3\ ft$ *(key width)*

$L := BWIDTH - TK = 9.5\ ft$ *(length of linear uplift pressure)*

$(\sigma_{UL})_{max} - (\sigma_{UL})_{min} = m(L)$ *(linear relationship)*

$m := \frac{(\sigma_{UL})_{max} - (\sigma_{UL})_{min}}{L} = \begin{bmatrix} 0.0128 \\ 0.0169 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship)*

$(\sigma_{UL})_{max.toe} := \overrightarrow{(m \cdot TWIDTH) + (\sigma_{UL})_{min}} = \begin{bmatrix} 0.629 \\ 0.682 \end{bmatrix} ksf$ *(uplift pressure at the connection of the toe to the foundation)*

$UL_{toe} := \frac{-TWIDTH \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)}{2} = \begin{bmatrix} -2.4 \\ -2.6 \end{bmatrix} klf$ *(uplift pressure resultant for the toe of the foundation)*

$(x_{UL})_{toe} := TWIDTH - \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{UL})_{max.toe}\right) + (\sigma_{UL})_{min}\right)}{3 \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)} = \begin{bmatrix} 2 \\ 2 \end{bmatrix} ft$

(distance from the connection of the toe to the resultant of the uplift pressure)

Load Combinations

Resisting Side Forces - on Toe

$LC1 := (\gamma_p)_{Serve.n} \cdot \left(D + EV_r + Hs_r + SP_{toe} + UL_{toe}\right) = \begin{bmatrix} -8.3 \\ -7.2 \end{bmatrix} klf$ *(load case 1 for infrequent flooding)*

$\Sigma F_{toe} := \max\left(\overrightarrow{|LC1|}\right) = 8.3\ klf$ *(maximum of the drained vs undrained cases)*

Factored Shear on Toe at Face of Stem

$(V_u)_{toe} := \Sigma F_{toe} = 8.3\ klf$ *(maximum factored shear in toe)*

Resultant Moment - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(D \cdot (x_D)_{toe}\right) + \left(\overrightarrow{Hs_r \cdot (x_{Hs})_r}\right) \\ + \left(\overrightarrow{EV_r \cdot (x_{EV})_r}\right) + \left(\overrightarrow{SP_{toe} \cdot (x_{SP})_{toe}}\right) \\ + \left(\overrightarrow{UL_{toe} \cdot (x_{UL})_{toe}}\right) \end{pmatrix} = \begin{bmatrix} -17.8 \\ -15.4 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case 1 for infrequent flooding)

Maximum Factored Moment in Toe at Face of Stem

$Mu_{toe} := \max(LC1) \cdot 1\ ft = -15.4\ kip \cdot ft$ *(resultant moment at base of floodwall stem per foot of wall)*

$Mu_{toe} := -Mu_{toe}$

Toe Reinforcement

Bottom Bars - Main Steel

$(d_b)_{toe.bot} := \text{Bar Size: \#8} = 1\ in$ *(bottom bar size in toe)*

$s_{toe.bot} := 12\ in$ *(bottom bar spacing in toe)*

$c_{toe.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in toe)*

$(A_s)_{toe.bot} := \dfrac{0.25 \cdot \pi \cdot (d_b)_{toe.bot}^{\ 2} \cdot b}{s_{toe.bot}} = 0.785\ in^2$ *(area of steel for bottom reinforcement in toe)*

$d_{toe.bot} := TTOE - c_{toe.bot} - \left(0.5 \cdot (d_b)_{toe.bot}\right) = 19.5\ in$ *(depth to reinforcement bottom reinforcement in toe)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{toe.bot} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\dfrac{0.05 \cdot \langle f'_c - 4000\ psi \rangle}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$a_{toe.bot} := \dfrac{(A_s)_{toe.bot} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{toe.bot}} = 0.6\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)*

$(\phi M_n)_{toe.bot} := \phi_b \cdot (A_s)_{toe.bot} \cdot (F_y)_{60} \cdot \left(d_{toe.bot} - \dfrac{a_{toe.bot}}{2}\right) = 67.8\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{toe} := Check\left(Mu_{toe}, (\phi M_n)_{toe.bot}\right) = [\text{“OK”} \quad 0.23]$ *(nominal flexural check)*

Minimum Required Steel for Flexure

Solve Constraints Values

$As_{req} := 1.5\ in^2$

$Mu_{toe} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \dfrac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$

$(As_{req})_{toe} := \text{find}\left(As_{req}\right) = 0.2\ in^2$ *(minimum required reinforcement for flexural strength)*

Minimum Required Steel per ACI

$(A_{s.min})_a := \dfrac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.785\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \dfrac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.8\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.785\ in^2$

$A_{s\_1.3} := (As_{req})_{toe} \cdot \frac{4}{3} = 0.3\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{toe.req} := \text{if } A_{s\_1.3} < (A_s)_{toe.bot} \ \| \ as \leftarrow (As_{req})_{toe} \ \text{else} \ \| \ as \leftarrow A_{s.min} = 0.241\ in^2$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{toe.bot} = 0.8\ in^2$ *(area of steel provided in the horizontal direction for the toe)*

$(Steel\_Check_{bot})_{toe} := Check\left((A_s)_{toe.req}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.3]$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.4\ in^2$

$(Steel\_Check_{bot.ts})_{toe} := Check\left((A_{s.min})_{temp}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.6]$

(check stem reinforcement to required t&s reinforcement)

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{toe.bot}}{\left(b \cdot d_{toe.bot}\right)} = 0.0034$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{toe} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.4]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{toe.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in toe)*

$s_{toe.lat} := 12\ in$ *(lateral bar spacing in toe)*

$c_{toe.lat} :=$ 4″ cover *(cover for lateral reinforcement in toe)*

Toe - Top Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

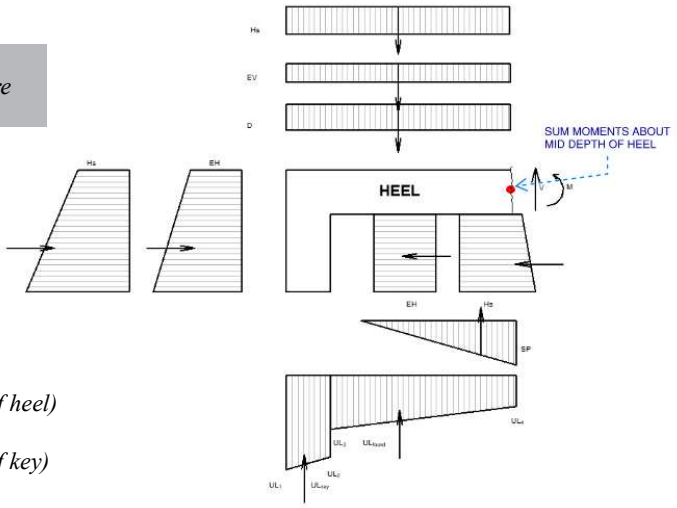
Toe - Top Lateral Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

HEEL DESIGN

Loads to Heel

Note: largest loading from drained and undrained cases used to create conservative design for loading. In each loading condition, drained loads are listed first and undrained last



$HWIDTH := BWIDTH - TTS - TWIDTH = 7\ ft$

(Length of heel, includes key)

Dead Load

$(\sigma_D)_{Heel} := \gamma_{conc} \cdot (TTOE) = 300\ psf$

$(\sigma_D)_{Key} := \gamma_{conc} \cdot (HK) = 300\ psf$

$D_{Heel} := (\sigma_D)_{Heel} \cdot HWIDTH = 2.1\ klf$ *(resultant dead load of heel)*

$D_{Key} := (\sigma_D)_{Key} \cdot TK = 0.9\ klf$ *(resultant dead load of key)*

$D := D_{Heel} + D_{Key} = 3\ klf$ *(resultant dead load of heel including key per linear foot of wall)*

$(x_{D.heel})_{heel} := \frac{HWIDTH}{2} = 3.5\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_{D.key})_{heel} := HWIDTH - \left(\frac{TK}{2}\right) = 5.5\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_D)_{heel} := \frac{D_{Heel} \cdot (x_{D.heel})_{heel} + D_{Key} \cdot (x_{D.key})_{heel}}{D_{Heel} + D_{Key}} = 4.1\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation including the key)*

Hydrostatic Loads - Top of Heel

Note: hydrostatic loads applied in three directions, notated as ah = above heel, fh = face of heel and bh = behind heel

$(\sigma_{Hs})_{ah} := \gamma_{water} \cdot HTS = 0.749\ ksf$ *(vertical water pressure from hydrostatic loading)*

$(Hs)_{ah} := (\sigma_{Hs})_{ah} \cdot HWIDTH = 5.2\ klf$ *(vertical water loading from hydrostatic loading)*

$(x_{Hs})_{ah} := \frac{HWIDTH}{2} = 3.5\ ft$ *(moment arm for vertical hydrostatic loading)*

Hydrostatic Loads - Face of Heel

$(\sigma_{Hs})_{fh.top} := \gamma_{water} \cdot HTS = 0.749\ ksf$ *(min horizontal hydrostatic loading, top of foundation)*

$(\sigma_{Hs})_{fh.bot} := \gamma_{water} \cdot (HTS + THEEL) = 0.998\ ksf$ *(min horizontal hydrostatic loading, bot of key)*

$THEEL = 4\ ft$ *(depth of applied loading)*

$(Hs)_{fh} := \frac{THEEL \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{2} = 3.5\ klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}\right) = 3.1\ ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.85 \\ 0.933 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.889 \\ 0.984 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 2\ ft$ *(depth of key from the back side face)*

$(Hs)_{bh} := \frac{HK \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{2} = \begin{bmatrix} 1.7 \\ 1.9 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}\right) = \begin{bmatrix} 2 \\ 2 \end{bmatrix} ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Face of Heel

$(\sigma_{EH})_{fh.top} := \gamma'_{soil} \cdot k_0 \cdot HSD = 0.076\ ksf$ *(min horizontal soil loading, top of foundation)*

$(\sigma_{EH})_{fh.bot} := \gamma'_{soil} \cdot k_0 \cdot (HSD + THEEL) = 0.199\ ksf$ *(min horizontal soil loading, top of foundation)*

Note: conservatively the lateral earth pressure does not include the undrained case where the lateral soil pressure would be zero.

$THEEL = 4\ ft$ *(depth of applied loading)*

$(EH)_{fh} := \frac{THEEL \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{2} = 0.6\ klf$ *(resultant of the soil loading to the front face of heel)*

$(x_{EH})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{3 \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}\right) = 3.296\ ft$ *(moment arm for the soil loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.81 \\ 1.1 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bh.bot} = \begin{bmatrix} 1.81 \\ 1.1 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 2\ ft$ *(depth of key from the back side face)*

$(EH)_{bh} := \frac{HK \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{2} = \begin{bmatrix} 3.6 \\ 2.2 \end{bmatrix} klf$ *(resultant of the horizontal soil loading to the back face of heel)*

$(x_{EH})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{3 \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}\right) = \begin{bmatrix} 2 \\ 2 \end{bmatrix} ft$ *(moment arm for the soil loading to the back face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Vertical Earth Pressures - Top of Heel

$(\sigma_{EV})_{ah} := \gamma'_{soil} \cdot HSD = 0.144\ ksf$ *(vertical buoyant soil pressure on heel)*

$(EV)_{ah} := (\sigma_{EV})_{ah} \cdot HWIDTH = 1.01\ klf$ *(vertical buoyant soil loading on heel)*

$(x_{EV})_{ah} := \frac{HWIDTH}{2} = 3.5\ ft$ *(moment arm for vertical soil loading)*

Soil Pressure Loading - Base of Heel

$L_0 := BWIDTH - BIC = \begin{bmatrix} 1.3 \\ 3.08 \end{bmatrix} ft$ *(length of base with no soil pressure loading, measured from front face of key back toward toe)*

$L := HWIDTH - L_0 = \begin{bmatrix} 5.7 \\ 3.92 \end{bmatrix} ft$ *(length of base with soil pressure loading, measured from beginning of pressure back toward connection)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{L}{(\sigma_{SP})_{heel}}$ *(similar triangles relationship between the total soil pressure load and the length of the base in compression to the length of the heel in compression to the maximum soil pressure loading at the connection)*

$(\sigma_{SP})_{heel} := \overrightarrow{-L \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} 0.8 \\ 0.57 \end{bmatrix} ksf$ *(maximum soil pressure loading at the connection of the heel)*

$SP_{heel} := \overrightarrow{0.5 \cdot (\sigma_{SP})_{heel} \cdot L} = \begin{bmatrix} 2.29 \\ 1.11 \end{bmatrix} klf$ *(resultant soil pressure loading on the heel)*

$(x_{SP})_{heel} := \frac{1}{3} L = \begin{bmatrix} 1.9 \\ 1.3 \end{bmatrix} ft$ *(moment arm for the soil pressure loading, measured from the connection of the heel)*

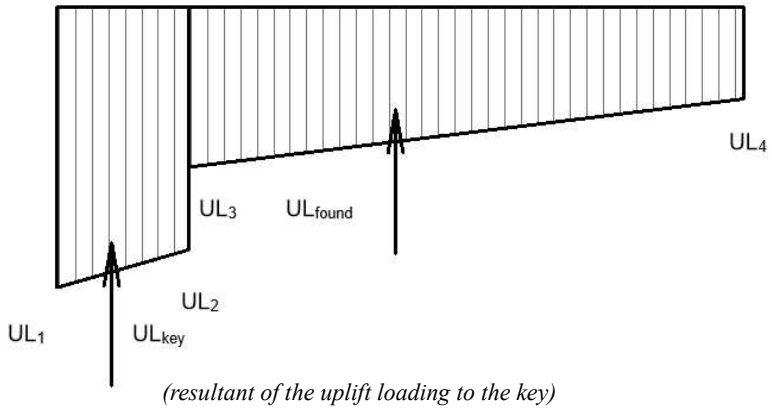
Uplifting Pressure

$UL_1 := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*



$UL_{key} := \frac{TK \cdot (UL_1 + UL_2)}{2} = \begin{bmatrix} 3.1 \\ 3.6 \end{bmatrix} klf$ *(resultant of the uplift loading to the key)*

$Heel\_Width := HWIDTH - TK = 4\ ft$ *(length of the heel; from the connection of the stem to the back face of the key)*

$(x_{UL})_{key} := Heel\_Width + \left(\frac{TK \cdot (2 \cdot UL_1 + UL_2)}{3 \cdot (UL_1 + UL_2)} \right) = \begin{bmatrix} 5.51 \\ 5.51 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

$m := \frac{(UL_4 - UL_3)}{BWIDTH - TK} = \begin{bmatrix} -0.0333 \\ -0.0438 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship between the uplift pressure from the foundation behind the key)*

$UL_{stem} := m \cdot (HWIDTH - TK) + UL_3 = \begin{bmatrix} 0.6 \\ 0.7 \end{bmatrix} ksf$ *(uplift pressure at the stem)*

$UL_{found} := \frac{Heel\_Width \cdot (UL_3 + UL_{stem})}{2} = \begin{bmatrix} 2.6 \\ 3.1 \end{bmatrix} klf$ *(resultant of the uplift loading to the foundation; less the key)*

$(x_{UL})_{found} := \left(\frac{Heel\_Width \cdot (2 \cdot UL_3 + UL_{stem})}{3 \cdot (UL_3 + UL_{stem})} \right) = \begin{bmatrix} 2.07 \\ 2.08 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

Load Combinations

Note: Forces that are oriented to the left and up are considered negative forces and moments that would rotate the heel counterclockwise are positive for the purpose of summing forces and moments.

Forces on Heel - Horizontal Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left((EH)_{fh} - (EH)_{bh} \right) \\ + \left((Hs)_{fh} - (Hs)_{bh} \right) \end{pmatrix} = \begin{bmatrix} -2.1 \\ -0.1 \end{bmatrix} klf$ *(Summation of the forces in the horizontal direction note positive forces represent heel in compression)*

$(\Sigma F_{heelc})_{horz} := \max(LC1) = -0.1\ klf$

$(\Sigma F_{heel})_{horz} := \max\left(\overrightarrow{|LC1|}\right) = 2.1\ klf$ *(maximum of the drained vs undrained cases)*

$P\_Check :=$ if $(\Sigma F_{heelc})_{horz} > 0$
"Heel is in compression, conservatively ignore axial loads in moment capcacity check"
else
"Heel in tension, factored into moment capcacity check"

$P\_Check =$ "Heel in tension, factored into moment capcacity check"

$(\Sigma F_{heel})_{Tension} :=$ if $(\Sigma F_{heel})_{horz} > 0$
$0\ kip$
else
$|(\Sigma F_{heel})_{horz}| \cdot b$
$= 0\ kip$

Forces on Heel - Vertical Forces

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} D + (EV)_{ah} + (Hs)_{ah} \\ + \left(UL_{key} + UL_{found}\right) + \left(SP_{heel}\right) \end{pmatrix} = \begin{bmatrix} 27.6 \\ 27.2 \end{bmatrix} klf$$

(summation of the forces in the vertical direction)

$$(\Sigma F_{heel})_{vert} := \max\left(LC1\right) = 27.6\ klf$$

(maximum of the drained vs undrained cases)

Resultant Shear at Base

$$Vu_{heel} := (\Sigma F_{heel})_{vert} = 27.6\ klf$$

(factored shear at connection of floodwall heel)

Resultant Axial Load in Base

$$(P_u)_{heel} := (\Sigma F_{heel})_{horz} = 2.1\ klf$$

(factored axial load at floodwall heel)

$$(\Sigma F_{heel})_{Tension} = 0\ ft \cdot klf$$

(tension in heel; from check above, zero if heel in compression)

Note: Axial loads with positive values put the heel of the floodwall in compression and negative values put the heel of the floodwall in tension.

Resultant Moment - on Heel at Stem Face

$$LC1_{pos} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \overrightarrow{\left(D \cdot (x_D)_{heel}\right)} \\ + \overrightarrow{\left((EV)_{ah} \cdot (x_{EV})_{ah}\right)} + \overrightarrow{\left((Hs)_{ah} \cdot (x_{Hs})_{ah}\right)} \\ + \overrightarrow{\left((EH)_{fh} \cdot (x_{EH})_{fh}\right)} + \overrightarrow{\left((Hs)_{fh} \cdot (x_{Hs})_{fh}\right)} \end{pmatrix} = 74.9\ \frac{kip \cdot ft}{ft}$$

(load case for positive bending moments applied to heel)

$$LC1_{neg} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \overrightarrow{\left((Hs)_{bh} \cdot (x_{Hs})_{bh}\right)} \\ + \overrightarrow{\left((EH)_{bh} \cdot (x_{EH})_{bh}\right)} \\ + \overrightarrow{\left(SP_{heel} \cdot (x_{SP})_{heel}\right)} \\ + \overrightarrow{\left(UL_{key} \cdot (x_{UL})_{key}\right)} \\ + \overrightarrow{\left(UL_{found} \cdot (x_{UL})_{found}\right)} \end{pmatrix} = \begin{bmatrix} 60 \\ 57.2 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case for negative bending moments applied to heel)

Resultant Moment at Base

$$\Sigma LC := \max\left(LC1_{pos} - LC1_{neg}\right) = 17.65\ kip$$

$$Mu_{heel} := \max\left(LC1_{pos} - LC1_{neg}\right) \cdot b = 17.7\ kip \cdot ft$$

(maximum factored moment at base of floodwall stem on the heel)

Note: since section is under tension and flexure, heel to be designed per section B-4 of EM 1110-2-2104.

Heel Reinforcement

$$Mu_{heel} = 17.7\ kip \cdot ft$$

(maximum factored moment at base of floodwall stem on the heel)

$$(P_u)_{heel} = 2.1\ \frac{kip}{ft}$$

(maximum factored axial tension at base of floodwall stem on the heel)

$$Vu_{heel} = 27.6\ \frac{kip}{ft}$$

(maximum factored shear at base of floodwall stem on the heel)

Top Bars - Main Steel

U.S.ARMY CORPS OF ENGINEERS - KANSAS CITY DISTRICT

T-Wall Load Cases and Strength Design

Upper Turkey Creek

Merriam, KS

ASSUMPTIONS

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

FLOOD LOAD CASES

Unusual Case

Top of Wall, ACE = 100 year event, Unusual Case

WSE = Top of Protection

Usual Case

ACE = 10 year event, Usual Case

WSE elevation below the top of the foundation

Note: The Unusual Flood Case with water to the top of the wall governs the design of this floodwall. Non-flood condition loads such as construction, seismic and wind are addressed in the stem design; however, it is apparent that the top of wall flood condition governs stability and the primary steel design so only the Unusual top of wall flood load is considered for stability and the base design.

The Usual Flood Case does not have water to the top of the foundation and is not included in these calculations.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$\gamma'_{soil} := \gamma_{soil} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$q_n := 2000\ psi$ *(bearing pressure, Reference DDR Table 9.2)*

Drained Soil Conditions

$\phi_{drained} := 28\ deg$ *(internal friction angle for drained soil condition)*

$C_{drained} := 0\ psf$ *(cohesion for drained soil condition)*

$k_0 := 1 - \sin\left(\phi_{drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

Undrained Soil Conditions

$\phi_{undrained} := 0\ deg$ *(internal friction angle for drained soil condition)*

$C_{undrained} := 1000\ psf$ *(cohesion for drained soil condition)*

$(k_0)_{undrained} := 1 - \sin\left(\phi_{undrained}\right) = 1$ *(at-rest soil pressure coefficient for the undrained condition)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(young's modulus of elasticity for steel)*

$(F_y)_{30} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$(F_y)_{60} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$\varepsilon_{ty} := \frac{(F_y)_{60}}{E_{steel}} = 0.0021$ *(yield strain of 60 ksi steel)*

Concrete Properties

$f'_c := 4500\ psi$ *(concrete compressive strength for all structures)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength for all structures)*

$q\lambda_c := 1.0$ *(concrete modification factor)*

$cover_3 := 3\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$cover_4 := 4\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$\gamma_{conc} := 150\ pcf$ *(concrete unit weight)*

$Ec := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$ *(young's modulus of elasticity for concrete)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

Load Factors

Serviceability Load Factors

Note: the unusual loading condition is used for the top of the floodwalls since they are designed to the 100 year event. the usual loading condition is defined as the 10 year event.

$(\gamma_p)_{Serve.u} := 2.2$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

$(\gamma_p)_{Serve.n} := 1.6$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

Strength Limit States

$\phi_b := 0.9$ *(bending load reduction factor - ACI 318-19 21.2.2, Table 21.2.2)*

$\phi_A := 0.9$

$\phi_V := 0.75$ *(shear load reduction factor - ACI 318-19 Table 21.2.1)*

CT WALL DATA

$(\sigma_{UL})_{min} := UL_4 = \begin{bmatrix} 0.296 \\ 0.327 \end{bmatrix} ksf$ *(minimum uplift pressure at the end of the toe)*

$(\sigma_{UL})_{max} := UL_3 = \begin{bmatrix} 0.475 \\ 0.577 \end{bmatrix} ksf$ *(maximum uplift pressure behind the key)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} := \begin{bmatrix} 0.756 \\ 0.883 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

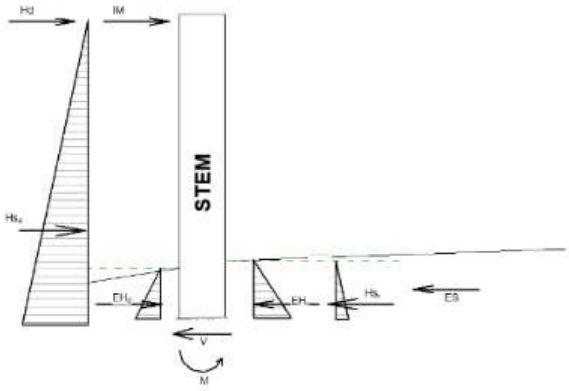
$(\sigma_{Hs})_{bh.bot} := \begin{bmatrix} 0.809 \\ 0.959 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

STEM DESIGN, RIVER SIDE

Loads to Stem

Note: largest loading from drained and undrained cases used to determine the controlling load case. In each loading condition, drained loads are listed first and undrained last.

This design for the riverside steel, along with the EnerCalc calculations, attached will be used for the landside steel design for simplicity. By inspection, the riverside reinforcement is sufficient for the landside reinforcement design.



Hydrostatic Loads

$\sigma_{Hsd} := \begin{bmatrix} \gamma_{water} \cdot HTS \\ \gamma_{water} \cdot HTS \end{bmatrix} = \begin{bmatrix} 624 \\ 624 \end{bmatrix} psf$ *(hydrostatic pressure loading to driving side)*

$Hs_d := \overrightarrow{0.5 \cdot \sigma_{Hsd} \cdot HTS} = \begin{bmatrix} 3.12 \\ 3.12 \end{bmatrix} klf$ *(hydrostatic loading to driving side)*

$(x_{Hs})_d := HTS \cdot \frac{1}{3} = 3.3\ ft$ *(moment arm for hydrostatic loading to the driving side from the base of the stem)*

Note: assume that hydrostatic loading from the resisting side of the T-wall provided from groundwater up to the ground surface. Assume that all additional water from the resisting side, landside, of the floodwall is conveyed away through interior drainage systems.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 105.5 \\ 105.5 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{0.5 \cdot \sigma_{Hsr} \cdot HSR} = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(hydrostatic loading to resisting side)*

$(x_{Hs})_r := HSR \cdot \frac{1}{3} = 0.56\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Lateral Earth Loading

$(\sigma_{EHd})_{stem} := \sigma_{EHd} \cdot \left(\frac{HSD}{HSD + THEEL} \right) = \begin{bmatrix} 0.046 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side of stem)*

$EH_d := \overrightarrow{0.5 \cdot (\sigma_{EHd})_{stem} \cdot HSD} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to driving side of stem)*

$(x_{EH})_d := HSD \cdot \frac{1}{3} = 0.6\ ft$ *(moment arm for lateral earth loading to the driving side from the base of the stem)*

$(\sigma_{EHr})_{stem} := \sigma_{EHr} \cdot \frac{HSR}{HSR + TTOE} = \begin{bmatrix} 0.041 \\ 0.034 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side of stem)*

$EH_r := \overrightarrow{0.5 \cdot (\sigma_{EHr})_{stem} \cdot HSR} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to resisting side of stem)*

$(x_{EH})_r := HSR \cdot \frac{1}{3} = 0.6\ ft$ *(moment arm for lateral earth loading to the resisting side from the base of the stem)*

Impact Loading

Note: reference DDR for discussion of impact loading on floodwalls.

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

$(x_{IM})_d := HTS = 10\ ft$ *(moment arm of the impact load from the base of the stem)*

Operating Equipment

$p_{const} := 250\ psf$ *(construction surcharge loading)*

Note: assume that the surcharge loading is uniform and that the resultant is mid-height of the soil depth.

$d_{soil} := HSR = 1.7\ ft$ *(depth of soil cover on stem)*

$(x_Q)_d := \frac{HSR}{2} = 0.8\ ft$ *(resultant height above base of stem)*

$x_Q := d_{soil} - (x_Q)_d = 0.8\ ft$ *(depth from resultant to top of soil)*

$\sigma_H := p_{const} \cdot k_0 = 0.133\ ksf$ *(lateral linear pressure applied to wall)*

$Q := \sigma_H \cdot HSR = 0.224\ klf$ *(lateral surcharge load to structure, usual case)*

Wind

Note: for conservative analysis, wind loading only applied to the driving side as a positive pressure or applied to the resisting side as a negative pressure.

$(p_w)_p := 30.4\ psf$ *(primary wind pressure, reference DDR)*

$(p_w)_c := 15.8\ psf$ *(companion wind pressure, reference DDR)*

$G := 0.85\ \frac{1}{ft}$ *(gust factor, ASCE 7-16 Section 26.11.1)*

$C_f := 1.3$ *(force coefficient from ASCE 7-16, figure 29.3-1, s/h = 1 and B/s = '>45')*

$d := HTS - HSR = 8.3\ ft$ *(exposed surface of the stem for wind pressure)*

$A_s := 1\ ft \cdot d = 8.3\ ft^2$ *(exposed surface area of the wall per linear foot)*

$W_c := (p_w)_c \cdot G \cdot C_f \cdot A_s = 0.145\ klf$ *(wind loading, usual case for companion loading)*

$W_p := (p_w)_p \cdot G \cdot C_f \cdot A_s = 0.279\ klf$ *(wind loading, unusual case)*

$(x_W)_d := HTS - \frac{d}{2} = 5.8\ ft$ *(resultant height above base of stem)*

Earthquake Loading: Equivalent Lateral Force

$D_{wall} := (TTS \cdot HTS) \cdot \gamma_{conc} = 2.3\ \frac{1}{ft} \cdot kip$ *(dead load of the stem of the wall)*

$I_e := 1.5$ *(importance factor, ASCE 7-16 Table 1.5-2)*

$R := 2.5$ *(response modification factor, ASCE 7-16, Table 12.2-1, Item G.3)*

$S_{DS} := 0.101$ *(seismic spectral acceleration for short period)*

$Cs := \frac{S_{DS}}{\frac{R}{I_e}} = 0.1$ *(seismic response coefficient, ASCE 7-16 12.8-2)*

$V := Cs \cdot D_{wall} = 0.1\ klf$ *(seismic base shear, ASCE 7-16, EQ 12.8-1)*

$EQ := V = 0.1\ klf$

$(x_{EQ}) := HSR = 1.7\ ft$ *(resultant height above base of stem)*

Load Combinations

Note: Usual design cases not considered here as the Usual pool level does not reach the base of the stem.

Driving Side Forces

$LC1_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Hs_d + IM) = \begin{bmatrix} 5.2 \\ 5.2 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot (EH_d + EQ) = \begin{bmatrix} 0.3 \\ 0.2 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Q) = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} klf$ *(load case 3 for construction)*

Resisting Side Forces

$LC1_r := (\gamma_p)_{Serve.n} \cdot (EH_r + Hs_r - W_c) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix} klf$ *(load case 4 for construction)*

Resultant Shear at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 5.2 \\ 5.2 \end{bmatrix} klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix} klf$ *(equilibrium load case 3)*

$\Sigma F_{stem} := \text{stack}(LC1, LC2, LC3)$

Note: Maximum factored shear loading to the stem is the governing loading for the river side steel design. Minimum factored shear loading is the governing landside steel design.

$(Vu)_{stem} := \max(\Sigma F_{stem}) = 5.2\ klf$ *(resultant factored shear at base of floodwall stem, driving side)*

Resultant Moment - Driving Side

$LC1_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Hs_d \cdot (x_{Hs})_d \right) + IM \cdot (x_{IM})_d \right) = \begin{bmatrix} 18.3 \\ 18.2 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(EQ \cdot (x_{EQ}) \right) \right) = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Q \cdot \left((x_Q)_d \right) \right) \right) = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction)*

Resultant Moment - Resisting Side

$LC1_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) + \left(Hs_r \cdot (x_{Hs})_r \right) \right) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum flooding)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0.03 \\ 0.03 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0.03 \\ 0.03 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction or surcharge loading)*

Resultant Moment at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 18.2 \\ 18.1 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 3)*

$\Sigma M_{stem} := \text{stack}(LC1, LC2, LC3)$ *(resultant factored moment at base of floodwall stem)*

$(Mu)_{stem} := \max(\Sigma M_{stem}) \cdot 1\ ft = 18.2\ kip \cdot ft$ *(resultant moment at base of floodwall stem, riverside steel design)*

Design Check Function

(system check for capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing arrays)

$$Check_v\left(X_U, X_N\right) := \left\| \begin{array}{l} \text{for } i \in \mathbf{ORIGIN} .. \text{last}\left(X_U\right) \\ \quad \left\| \begin{array}{l} \text{if } X_{U_i} > X_{N_i} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“NO GOOD”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \\ \text{else if } X_{N_i} = 0 \\ \quad \left\| ch_{i,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“OK”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing scalar values)

$$Check\left(X_U, X_N\right) := \left\| \begin{array}{l} \text{if } X_U > X_N \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“NO GOOD”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ \text{else if } X_U = 0 \\ \quad \left\| ch_{1,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“OK”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

$b := 12\ in$ *(strip width for analysis)*

Stem Reinforcement

Vertical Bars

$(d_b)_{stem.vert} :=$ Bar Size: #8 $= 1\ in$ *(vertical bar size in stem)*

$s_{stem.vert} := 12\ in$ *(vertical bar spacing in stem)*

$c_{stem.vert} :=$ 3″ cover *(cover for vertical reinforcement in stem)*

$$(A_s)_{stem.vert} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.vert}^{\ 2} \cdot b}{s_{stem.vert}} = 0.785\ in^2$$ *(area of steel vertical reinforcement in stem)*

$d_{stem.vert} := TTS - c_{stem.vert} - \left(0.5 \cdot (d_b)_{stem.vert}\right) = 14.5\ in$ *(depth to reinforcement vertical reinforcement in stem)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{stem} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$$a_{stem.vert} := \frac{(A_s)_{stem.vert} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}} = 0.85\ in$$

(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)

$$(\phi M_n)_{stem.vert} := \phi_b \cdot (A_s)_{stem.vert} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{a_{stem.vert}}{2}\right) = 49.7\ kip \cdot ft$$

(nominal flexural strength, EM1110-2-2104, B-49)

$$(Flex_{nom})_{Stem} := Check\left((Mu)_{stem}, (\phi M_n)_{stem.vert}\right) = [\text{"OK"} \quad 0.37]$$

(nominal flexural check, with Utilization ratio)

Minimum Required Steel for Flexure

Solve Constraints Given Values

$$As_{req} := 1.5\ in^2$$

$$(Mu)_{stem} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$$

$$As_{req.stem} := \mathbf{find}\left(\mathbf{As_{req}}\right) = 0.284\ in^2$$

$$(A_{s.min})_{stem.ten} := As_{req.stem} = 0.284\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.584\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.58\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTS \cdot b) = 0.324\ in^2$$

(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$

(minimum area of steel required for flexural capacity)

$$A_{s.min} = 0.584\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{stem.ten} \cdot \frac{4}{3} = 0.379\ in^2$$

(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)

$$(A_s)_{stem.req} := \begin{cases} as \leftarrow (A_{s.min})_{stem.ten} & \text{if } A_{s\_1.3} < (A_s)_{stem.vert} \\ as \leftarrow A_{s.min} & \text{else} \end{cases} = 0.284\ in^2$$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{stem.vert} = 0.8\ in^2$$

(area of steel provided in the vertical direction for the stem)

$$(Steel\_Check_{Vert})_{Stem} := Check\left((A_s)_{stem.req}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$$

(check stem reinforcement to required reinforcement)

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Vert.ts})_{Stem} := Check\left((A_{s.min})_{temp}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$ *(check stem reinforcement to temperature and shrinkage requirements)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{stem.vert}}{\left(b \cdot d_{stem.vert}\right)} = 0.0045$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{Stem} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{stem.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in stem)*

$s_{stem.lat} := 12\ in$ *(lateral bar spacing in stem)*

$(A_s)_{stem.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.lat}^{\ 2} \cdot 12\ in}{s_{stem.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in stem)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot \left(TTS \cdot b\right)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.3\ in^2$

$(A_s)_{stem.lat} = 0.4\ in^2$ *(area of steel provided in the lateral direction for the stem)*

$(Steel\_Check_{Lat})_{Stem} := Check\left(A_{s.req}, (A_s)_{stem.lat}\right) = [\text{"OK"} \quad 0.7]$ *(check stem reinforcement to required reinforcement)*

Riverside Reinforcement

Primary Reinforcement

$(d_b)_{stem.vert} = 1\ in$ *bars located at* $s_{stem.vert} = 12\ in$ *centers*

Lateral Reinforcement

$(d_b)_{stem.lat} = 0.75\ in$ *bars located at* $s_{stem.lat} = 12\ in$ *centers*

Deflection Check

Note: Reference provided justification file for loading conditions and attached EnerCalc calculations for the deflections in floodwall stem since stem thickness is less than H/8. From EnerCalc report, wall deflections limited to H/6838, which is less than expected movement capacity in waterstop and wall joints. 10 ft tall floodwalls to have stems with above detailed reinforcement.

Landside Reinforcement

For design simplicity, landside reinforcement to match both primary and lateral reinforcement.

STEM SHEAR CONNECTION TO FOUNDATION

Shear Friction

$f_y := (F_y)_{60} = 60000\ psi$ *(yield strength of reinforcing steel)*

$\mu := 1.0$

$(d_b)_{stem.vert.2} :=$ Bar Size: #6 $= 0.75\ in$ *(vertical bar size in stem)*

$s_{stem.vert2} := 12\ in$

$A_{vf} := \left(\frac{\pi}{4}\right) \cdot (d_b)_{stem.vert.2}{}^2 \cdot \left(\frac{b}{s_{stem.vert2}}\right) = 0.4\ in^2$

$V_n := \mu \cdot A_{vf} \cdot f_y = 26.5\ kip$ *(shear-friction strength, ACI 318-19, eq 22.9.4.2)*

Table 22.9.4.2—Coefficients of friction

Contact surface condition	Coefficient of friction μ[1]	
Concrete placed monolithically	1.4λ	(a)
Concrete placed against hardened concrete that is clean, free of laitance, and intentionally roughened to a full amplitude of approximately 1/4 in.	1.0λ	(b)
Concrete placed against hardened concrete that is clean, free of laitance, and not intentionally roughened	0.6λ	(c)
Concrete placed against as-rolled structural steel that is clean, free of paint, and with shear transferred across the contact surface by headed studs or by welded deformed bars or wires.	0.7λ	(d)

[1]λ = 1.0 for normalweight concrete. For lightweight concrete, λ is calculated as given in 19.2.4, but shall not exceed 0.85.

Maximum Shear Friction

$A_c := b \cdot TTS = 1.5\ ft^2$

$(V_n)_a := 0.2\ f'_c \cdot A_c = 194.4\ kip$ *(shear-friction maximum, equation a, Table 22.9.4.4)*

$(V_n)_b := \left(480\ psi + 0.08 \cdot f'_c\right) \cdot A_c = 181.4\ kip$ *(shear-friction maximum, equation b, Table 22.9.4.4)*

$(V_n)_c := \left(16000\ psi\right) A_c = 3456\ kip$ *(shear-friction maximum, equation c, Table 22.9.4.4)*

Table 22.9.4.4—Maximum V_n across the assumed shear plane

Condition	Maximum V_n		
Normalweight concrete placed monolithically or placed against hardened concrete intentionally roughened to a full amplitude of approximately 1/4 in.	Least of (a), (b), and (c)	$0.2f'_cA_c$	(a)
		$(480 + 0.08f'_c)A_c$	(b)
		$1600A_c$	(c)
Other cases	Lesser of (d) and (e)	$0.2f'_cA_c$	(d)
		$800A_c$	(e)

$(V_n)_{max} := \max\left((V_n)_a, (V_n)_b, (V_n)_c\right) = 3456\ kip$ *(shear-friction maximum, Table 22.9.4.4)*

Shear Strength

$\phi_V = 0.75$ *(reduction factor for shear capacity)*

$\phi_V V_n := \phi_V \cdot min\left((V_n)_{max}, V_n\right) = 19.9\ kip$ *(factored shear-friction strength)*

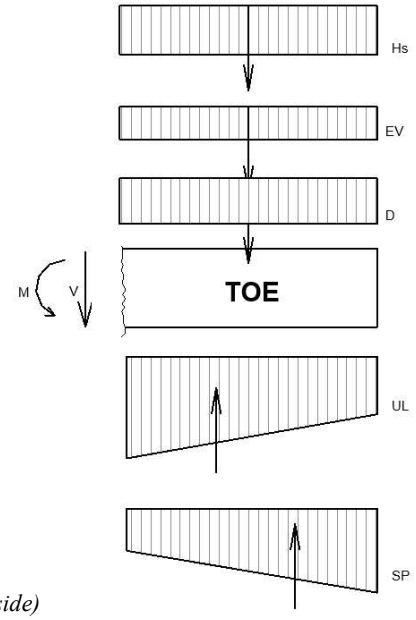
$V_{stem} := (Vu)_{stem} \cdot b = 5.2\ kip$ *(calculated shear required at base of stem)*

$V_{check} := Check\left(V_{stem}, \phi_V V_n\right) = [\text{"OK"} \quad 0.3]$ *(shear check, utilization ratio)*

Toe Check

Loads to Toe

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



Dead Load

$\sigma_D := \gamma_{conc} \cdot TTOE = 300\ psf$

$D := \sigma_D \cdot TWIDTH = 0.8\ klf$ *(resultant dead load of toe)*

$(x_D)_{toe} := \frac{TWIDTH}{2} = 1.3\ ft$ *(moment arm of the dead loading from the connection of the toe to the foundation)*

Hydrostatic Loads Above Toe

Note: Groundwater assumed to the soil surface. Potential additional seepage pressure conservatively ignored.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 105.5 \\ 105.5 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{TWIDTH \cdot \sigma_{Hsr}} = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} klf$ *(Resultant hydrostatic loading to resisting side)*

$(x_{Hs})_r := TWIDTH \cdot 0.5 = 1.25\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Vertical Earth Pressure

$\sigma_{EV} := \gamma'_{soil} \cdot HSR = 97.3\ psf$

$EV_r := \begin{bmatrix} \sigma_{EV} \cdot TWIDTH \\ \sigma_{EV} \cdot TWIDTH \end{bmatrix} = \begin{bmatrix} 0.243 \\ 0.243 \end{bmatrix} klf$ *(buoyant force of vertical soil loading)*

$(x_{EV})_r := \frac{TWIDTH}{2} = 1.3\ ft$

Soil Pressure

$(\sigma_{SP})_{max} = \begin{bmatrix} -1.421 \\ -1.45 \end{bmatrix} ksf$ *(max soil loading from CT Wall Output)*

$BWIDTH = 13\ ft$ *(total length of base of wall)*

$BIC_{percent} := \begin{bmatrix} 89.61 \\ 75.35 \end{bmatrix}\%$ *(percent of the base in compression)*

$BIC := BWIDTH \cdot BIC_{percent} = \begin{bmatrix} 11.6 \\ 9.8 \end{bmatrix} ft$ *(length of base in compression)*

$TWIDTH = 2.5\ ft$ *(length of toe of the foundation)*

note: using the length of the toe to determine the soil loading at the the connection of the toe to the stem and heel, use similar triangles to determine the loading at the connection of the toe.

$NTWIDTH := BIC - TWIDTH = \begin{bmatrix} 9.1 \\ 7.3 \end{bmatrix} ft$ *(length of the not-toe of the foundation in compression)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{NTWIDTH}{(\sigma_{SP})_1}$ *(relationship of similar triangles)*

$(\sigma_{SP})_1 := \overrightarrow{NTWIDTH \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} -1.12 \\ -1.08 \end{bmatrix} ksf$ *(soil pressure loading at the connection of the toe)*

$SP_{toe} := \frac{TWIDTH \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)}{2} = \begin{bmatrix} -3.2 \\ -3.2 \end{bmatrix} klf$ *(resultant soil loading to the toe of the foundation)*

$$(x_{SP})_{toe} := \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{SP})_{max}\right) + (\sigma_{SP})_1\right)}{3 \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)} = \begin{bmatrix} 1.3 \\ 1.3 \end{bmatrix} ft$$

(moment arm from the connection of the toe to the resultant of the soil pressure loading)

Uplift Pressures

$$(\sigma_{UL})_{min} = \begin{bmatrix} 0.296 \\ 0.327 \end{bmatrix} ksf$$

(minimum uplift pressure at the end of the toe)

$$(\sigma_{UL})_{max} = \begin{bmatrix} 0.475 \\ 0.577 \end{bmatrix} ksf$$

(maximum uplift pressure behind the key)

Note: Uplift pressure drops off linearly from the back of the key to the toe of the foundation

$BWIDTH = 13\ ft$ *(foundation width)*

$TK = 3\ ft$ *(key width)*

$L := BWIDTH - TK = 10\ ft$ *(length of linear uplift pressure)*

$(\sigma_{UL})_{max} - (\sigma_{UL})_{min} = m(L)$ *(linear relationship)*

$$m := \frac{(\sigma_{UL})_{max} - (\sigma_{UL})_{min}}{L} = \begin{bmatrix} 0.0179 \\ 0.025 \end{bmatrix} \frac{ksf}{ft}$$

(linear relationship)

$$(\sigma_{UL})_{max.toe} := \overrightarrow{(m \cdot TWIDTH) + (\sigma_{UL})_{min}} = \begin{bmatrix} 0.341 \\ 0.39 \end{bmatrix} ksf$$

(uplift pressure at the connection of the toe to the foundation)

$$UL_{toe} := \frac{-TWIDTH \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)}{2} = \begin{bmatrix} -0.8 \\ -0.9 \end{bmatrix} klf$$

(uplift pressure resultant for the toe of the foundation)

$$(x_{UL})_{toe} := TWIDTH - \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{UL})_{max.toe}\right) + (\sigma_{UL})_{min}\right)}{3 \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)} = \begin{bmatrix} 1.2 \\ 1.2 \end{bmatrix} ft$$

(distance from the connection of the toe to the resultant of the uplift pressure)

Load Combinations

Resisting Side Forces - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \left(D + EV_r + Hs_r + SP_{toe} + UL_{toe}\right) = \begin{bmatrix} -4.3 \\ -4.5 \end{bmatrix} klf$$

(load case 1 for infrequent flooding)

$$\Sigma F_{toe} := \max\left(\overrightarrow{|LC1|}\right) = 4.5\ klf$$

(maximum of the drained vs undrained cases)

Factored Shear on Toe at Face of Stem

$$(V_u)_{toe} := \Sigma F_{toe} = 4.5\ klf$$

(maximum factored shear in toe)

Resultant Moment - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(D \cdot (x_D)_{toe}\right) + \left(\overrightarrow{Hs_r \cdot (x_{Hs})_r}\right) \\ + \left(\overrightarrow{EV_r \cdot (x_{EV})_r}\right) + \left(\overrightarrow{SP_{toe} \cdot (x_{SP})_{toe}}\right) \\ + \left(\overrightarrow{UL_{toe} \cdot (x_{UL})_{toe}}\right) \end{pmatrix} = \begin{bmatrix} -5.6 \\ -5.9 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case 1 for infrequent flooding)

Maximum Factored Moment in Toe at Face of Stem

$$Mu_{toe} := \max(LC1) \cdot 1\ ft = -5.6\ kip \cdot ft$$

(resultant moment at base of floodwall stem per foot of wall)

$$Mu_{toe} := -Mu_{toe}$$

Toe Reinforcement

Bottom Bars - Main Steel

$(d_b)_{toe.bot} := \text{Bar Size: \#8} = 1\ in$ *(bottom bar size in toe)*

$s_{toe.bot} := 12\ in$ *(bottom bar spacing in toe)*

$c_{toe.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in toe)*

$(A_s)_{toe.bot} := \dfrac{0.25 \cdot \pi \cdot (d_b)_{toe.bot}^{\ 2} \cdot b}{s_{toe.bot}} = 0.785\ in^2$ *(area of steel for bottom reinforcement in toe)*

$d_{toe.bot} := TTOE - c_{toe.bot} - \left(0.5 \cdot (d_b)_{toe.bot}\right) = 19.5\ in$ *(depth to reinforcement bottom reinforcement in toe)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{toe.bot} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\dfrac{0.05 \cdot \langle f'_c - 4000\ psi \rangle}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$a_{toe.bot} := \dfrac{(A_s)_{toe.bot} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{toe.bot}} = 0.6\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)*

$(\phi M_n)_{toe.bot} := \phi_b \cdot (A_s)_{toe.bot} \cdot (F_y)_{60} \cdot \left(d_{toe.bot} - \dfrac{a_{toe.bot}}{2}\right) = 67.8\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{toe} := Check\left(Mu_{toe}, (\phi M_n)_{toe.bot}\right) = [\text{“OK”} \quad 0.08]$ *(nominal flexural check)*

Minimum Required Steel for Flexure

Solve Constraints Values

$As_{req} := 1.5\ in^2$

$Mu_{toe} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \dfrac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$

$(As_{req})_{toe} := \text{find}\left(As_{req}\right) = 0.1\ in^2$ *(minimum required reinforcement for flexural strength)*

Minimum Required Steel per ACI

$(A_{s.min})_a := \dfrac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.785\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \dfrac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.8\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.785\ in^2$

$A_{s\_1.3} := (As_{req})_{toe} \cdot \frac{4}{3} = 0.1\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{toe.req} := \text{if } A_{s\_1.3} < (A_s)_{toe.bot} \ \| \ as \leftarrow (As_{req})_{toe} \ \text{else} \ \| \ as \leftarrow A_{s.min} = 0.087\ in^2$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{toe.bot} = 0.8\ in^2$ *(area of steel provided in the horizontal direction for the toe)*

$(Steel\_Check_{bot})_{toe} := Check\left((A_s)_{toe.req}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.1]$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Reinforcement

Toe - Top Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

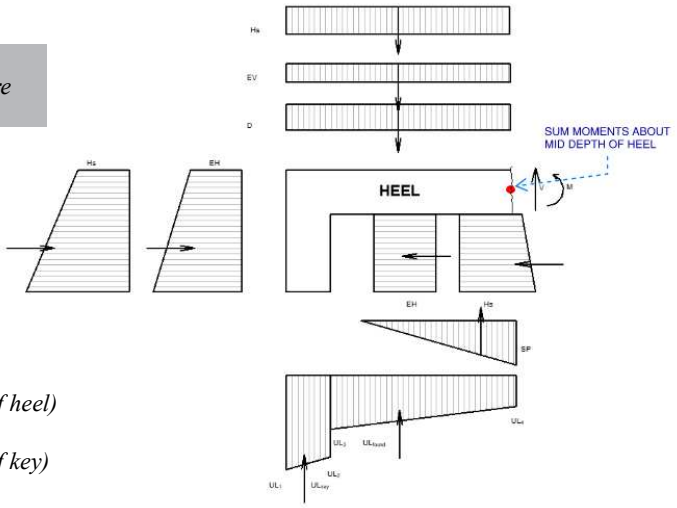
Toe - Top Lateral Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

HEEL DESIGN

Loads to Heel

Note: largest loading from drained and undrained cases used to create conservative design for loading. In each loading condition, drained loads are listed first and undrained last



$HWIDTH := BWIDTH - TTS - TWIDTH = 9\ ft$

(Length of heel, includes key)

Dead Load

$(\sigma_D)_{Heel} := \gamma_{conc} \cdot (TTOE) = 300\ psf$

$(\sigma_D)_{Key} := \gamma_{conc} \cdot (HK) = 525\ psf$

$D_{Heel} := (\sigma_D)_{Heel} \cdot HWIDTH = 2.7\ klf$ *(resultant dead load of heel)*

$D_{Key} := (\sigma_D)_{Key} \cdot TK = 1.6\ klf$ *(resultant dead load of key)*

$D := D_{Heel} + D_{Key} = 4.3\ klf$ *(resultant dead load of heel including key per linear foot of wall)*

$(x_{D.heel})_{heel} := \frac{HWIDTH}{2} = 4.5\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_{D.key})_{heel} := HWIDTH - \left(\frac{TK}{2}\right) = 7.5\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_D)_{heel} := \frac{D_{Heel} \cdot (x_{D.heel})_{heel} + D_{Key} \cdot (x_{D.key})_{heel}}{D_{Heel} + D_{Key}} = 5.6\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation including the key)*

Hydrostatic Loads - Top of Heel

Note: hydrostatic loads applied in three directions, notated as ah = above heel, fh = face of heel and bh = behind heel

$(\sigma_{Hs})_{ah} := \gamma_{water} \cdot HTS = 0.624\ ksf$ *(vertical water pressure from hydrostatic loading)*

$(Hs)_{ah} := (\sigma_{Hs})_{ah} \cdot HWIDTH = 5.6\ klf$ *(vertical water loading from hydrostatic loading)*

$(x_{Hs})_{ah} := \frac{HWIDTH}{2} = 4.5\ ft$ *(moment arm for vertical hydrostatic loading)*

Hydrostatic Loads - Face of Heel

$(\sigma_{Hs})_{fh.top} := \gamma_{water} \cdot HTS = 0.624\ ksf$ *(min horizontal hydrostatic loading, top of foundation)*

$(\sigma_{Hs})_{fh.bot} := \gamma_{water} \cdot (HTS + THEEL) = 0.967\ ksf$ *(min horizontal hydrostatic loading, bot of key)*

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(Hs)_{fh} := \frac{THEEL \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{2} = 4.4\ klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}\right) = 3.95\ ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.756 \\ 0.883 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.809 \\ 0.959 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(Hs)_{bh} := \frac{HK \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{2} = \begin{bmatrix} 2.7 \\ 3.2 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}\right) = \begin{bmatrix} 2.8 \\ 2.8 \end{bmatrix} ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Face of Heel

$(\sigma_{EH})_{fh.top} := \gamma'_{soil} \cdot k_0 \cdot HSD = 0.052\ ksf$ *(min horizontal soil loading, top of foundation)*

$(\sigma_{EH})_{fh.bot} := \gamma'_{soil} \cdot k_0 \cdot (HSD + THEEL) = 0.22\ ksf$ *(min horizontal soil loading, top of foundation)*

Note: conservatively the lateral earth pressure does not include the undrained case where the lateral soil pressure would be zero.

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(EH)_{fh} := \frac{THEEL \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{2} = 0.7\ klf$ *(resultant of the soil loading to the front face of heel)*

$(x_{EH})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{3 \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}\right) = 4.318\ ft$ *(moment arm for the soil loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.2 \\ 1.01 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bh.bot} = \begin{bmatrix} 1.2 \\ 1.01 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(EH)_{bh} := \frac{HK \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{2} = \begin{bmatrix} 4.2 \\ 3.5 \end{bmatrix} klf$ *(resultant of the horizontal soil loading to the back face of heel)*

$(x_{EH})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{3 \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}\right) = \begin{bmatrix} 2.8 \\ 2.8 \end{bmatrix} ft$ *(moment arm for the soil loading to the back face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Vertical Earth Pressures - Top of Heel

$(\sigma_{EV})_{ah} := \gamma'_{soil} \cdot HSD = 0.097\ ksf$ *(vertical buoyant soil pressure on heel)*

$(EV)_{ah} := (\sigma_{EV})_{ah} \cdot HWIDTH = 0.88\ klf$ *(vertical buoyant soil loading on heel)*

$(x_{EV})_{ah} := \frac{HWIDTH}{2} = 4.5\ ft$ *(moment arm for vertical soil loading)*

Soil Pressure Loading - Base of Heel

$L_0 := BWIDTH - BIC = \begin{bmatrix} 1.35 \\ 3.2 \end{bmatrix} ft$ *(length of base with no soil pressure loading, measured from front face of key back toward toe)*

$L := HWIDTH - L_0 = \begin{bmatrix} 7.65 \\ 5.8 \end{bmatrix} ft$ *(length of base with soil pressure loading, measured from beginning of pressure back toward connection)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{L}{(\sigma_{SP})_{heel}}$ *(similar triangles relationship between the total soil pressure load and the length of the base in compression to the length of the heel in compression to the maximum soil pressure loading at the connection)*

$(\sigma_{SP})_{heel} := \overrightarrow{-L \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} 0.93 \\ 0.86 \end{bmatrix} ksf$ *(maximum soil pressure loading at the connection of the heel)*

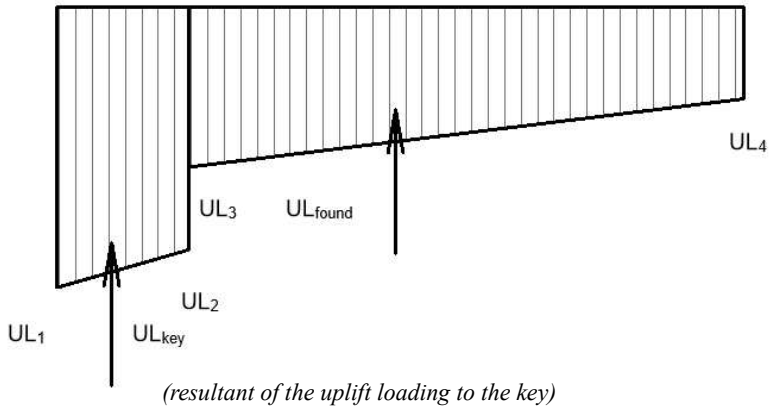
$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*



$UL_{key} := \frac{TK \cdot (UL_1 + UL_2)}{2} = \begin{bmatrix} 3.1 \\ 3.6 \end{bmatrix} klf$ *(resultant of the uplift loading to the key)*

$Heel\_Width := HWIDTH - TK = 6\ ft$ *(length of the heel; from the connection of the stem to the back face of the key)*

$(x_{UL})_{key} := Heel\_Width + \left(\frac{TK \cdot (2 \cdot UL_1 + UL_2)}{3 \cdot (UL_1 + UL_2)} \right) = \begin{bmatrix} 7.51 \\ 7.51 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

$m := \frac{(UL_4 - UL_3)}{BWIDTH - TK} = \begin{bmatrix} -0.0316 \\ -0.0416 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship between the uplift pressure from the foundation behind the key)*

$UL_{stem} := m \cdot (HWIDTH - TK) + UL_3 = \begin{bmatrix} 0.5 \\ 0.6 \end{bmatrix} ksf$ *(uplift pressure at the stem)*

$UL_{found} := \frac{Heel\_Width \cdot (UL_3 + UL_{stem})}{2} = \begin{bmatrix} 3.8 \\ 4.4 \end{bmatrix} klf$ *(resultant of the uplift loading to the foundation; less the key)*

$(x_{UL})_{found} := \left(\frac{Heel\_Width \cdot (2 \cdot UL_3 + UL_{stem})}{3 \cdot (UL_3 + UL_{stem})} \right) = \begin{bmatrix} 3.15 \\ 3.17 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

Load Combinations

Note: Forces that are oriented to the left and up are considered negative forces and moments that would rotate the heel counterclockwise are positive for the purpose of summing forces and moments.

Forces on Heel - Horizontal Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left((EH)_{fh} - (EH)_{bh} \right) \\ + \left((Hs)_{fh} - (Hs)_{bh} \right) \end{pmatrix} = \begin{bmatrix} -2.9 \\ -2.6 \end{bmatrix} klf$ *(Summation of the forces in the horizontal direction note positive forces represent heel in compression)*

$(\Sigma F_{heelc})_{horz} := \max(LC1) = -2.6\ klf$

$(\Sigma F_{heel})_{horz} := \max\left(\overrightarrow{|LC1|}\right) = 2.9\ klf$ *(maximum of the drained vs undrained cases)*

$P\_Check :=$ if $(\Sigma F_{heelc})_{horz} > 0$
"Heel is in compression, conservatively ignore axial loads in moment capcacity check"
else
"Heel in tension, factored into moment capcacity check"

$P\_Check =$ "Heel in tension, factored into moment capcacity check"

$(\Sigma F_{heel})_{Tension} :=$ if $(\Sigma F_{heel})_{horz} > 0$ $= 0\ kip$
$0\ kip$
else
$|(\Sigma F_{heel})_{horz}| \cdot b$

Forces on Heel - Vertical Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} D + (EV)_{ah} + (Hs)_{ah} \\ + \left(UL_{key} + UL_{found}\right) + \left(SP_{heel}\right) \end{pmatrix} = \begin{bmatrix} 33.9 \\ 33.9 \end{bmatrix} klf$ *(summation of the forces in the vertical direction)*

$(\Sigma F_{heel})_{vert} := \max\left(LC1\right) = 33.9\ klf$ *(maximum of the drained vs undrained cases)*

Resultant Shear at Base

$Vu_{heel} := (\Sigma F_{heel})_{vert} = 33.9\ klf$ *(factored shear at connection of floodwall heel)*

Resultant Axial Load in Base

$(P_u)_{heel} := (\Sigma F_{heel})_{horz} = 2.9\ klf$ *(factored axial load at floodwall heel)*

$(\Sigma F_{heel})_{Tension} = 0\ ft \cdot klf$ *(tension in heel; from check above, zero if heel in compression)*

Note: Axial loads with positive values put the heel of the floodwall in compression and negative values put the heel of the floodwall in tension.

Resultant Moment - on Heel at Stem Face

$LC1_{pos} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{D \cdot (x_D)_{heel}}\right) \\ + \left(\overrightarrow{(EV)_{ah} \cdot (x_{EV})_{ah}}\right) + \left(\overrightarrow{(Hs)_{ah} \cdot (x_{Hs})_{ah}}\right) \\ + \left(\overrightarrow{(EH)_{fh} \cdot (x_{EH})_{fh}}\right) + \left(\overrightarrow{(Hs)_{fh} \cdot (x_{Hs})_{fh}}\right) \end{pmatrix} = 117.9\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{neg} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{(Hs)_{bh} \cdot (x_{Hs})_{bh}}\right) \\ + \left(\overrightarrow{(EH)_{bh} \cdot (x_{EH})_{bh}}\right) \\ + \left(\overrightarrow{SP_{heel} \cdot (x_{SP})_{heel}}\right) \\ + \left(\overrightarrow{UL_{key} \cdot (x_{UL})_{key}}\right) \\ + \left(\overrightarrow{UL_{found} \cdot (x_{UL})_{found}}\right) \end{pmatrix} = \begin{bmatrix} 101.3 \\ 102.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$\Sigma LC := \max\left(LC1_{pos} - LC1_{neg}\right) = 16.61\ kip$

$Mu_{heel} := \max\left(LC1_{pos} - LC1_{neg}\right) \cdot b = 16.6\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

Note: since section is under tension and flexure, heel to be designed per section B-4 of EM 1110-2-2104.

Heel Reinforcement

$Mu_{heel} = 16.6\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

$(P_u)_{heel} = 2.9\ \frac{kip}{ft}$ *(maximum factored axial tension at base of floodwall stem on the heel)*

$Vu_{heel} = 33.9\ \frac{kip}{ft}$ *(maximum factored shear at base of floodwall stem on the heel)*

Top Bars - Main Steel

$(d_b)_{heel.top} :=$ Bar Size: #8 $= 1\ in$ *(top bar size in heel)*

$(d_b)_{heel.bot} :=$ Bar Size: #8 $= 1\ in$ *(bottom bar size in heel)*

$s_{heel.top} := 12\ in$ *(top bar spacing in heel)*

$s_{heel.bot} := 12\ in$ *(bottom bar spacing in heel)*

$c_{heel.top} := 3''\ \text{cover}$ *(cover for top reinforcement in heel)*

$c_{heel.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in heel)*

$(A_s)_{heel.top} := \frac{0.25 \cdot \pi \cdot (d_b)_{heel.top}^{\ 2} \cdot 12\ in}{s_{heel.top}} = 0.785\ in^2$ *(area of steel for top reinforcement in heel)*

$(A_s)_{heel.bot} := \frac{0.25 \cdot \pi \cdot (d_b)_{heel.bot}^{\ 2} \cdot 12\ in}{s_{heel.bot}} = 0.785\ in^2$ *(area of steel for top reinforcement in heel)*

$\rho := \frac{(A_s)_{heel.top}}{b \cdot TTOE} = 0.003$ *(reinforcement ratio for primary tension steel)*

$\rho' := \frac{(A_s)_{heel.bot}}{b \cdot TTOE} = 0.003$ *(reinforcement ratio for bottom tension steel)*

$d_{heel.top} := TTOE - c_{heel.top} - 0.5 \cdot (d_b)_{heel.top} = 20.5\ in$ *(depth to top reinforcement in heel)*

$a \cdot 0.85 \cdot f'c \cdot (d_b)_{heel.top} = (A_s)_{heel.top} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{heel.top} := \frac{(A_s)_{heel.top} \cdot (F_y)_{60} + (P_u)_{heel} \cdot b}{0.85 \cdot f'_c \cdot d_{heel.top}} = 0.64\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1)*

Axial Strength Check

$Pn_{max} := \left((A_s)_{heel.top} \cdot (F_y)_{60} + (A_s)_{heel.bot} \cdot (F_y)_{60}\right) = 94.2\ kip$ *(design axial strength, EM 1110-2-2104, Eq B-44)*

$\phi Pn := \phi_A \cdot Pn_{max} = 84.8\ kip$

$AxialCheck := Check\left((\Sigma F_{heel})_{horz} \cdot b, \phi Pn\right) = [\text{“OK”} \quad 0.03]$ *(tensile)*

Flexural Check

$\phi M_{n.Heel} := \phi_b \cdot \left(0.85 \cdot f'_c \cdot a_{heel.top} \cdot b \cdot \left(d_{heel.top} - \frac{a_{heel.top}}{2}\right) - (P_u)_{heel} \cdot \left(d_{heel.top} - \frac{TTOE}{2}\right) \cdot b\right) = 42.5\ kip \cdot ft$

(moment capacity for beam in flexure and axial tension, EM 2104, Eq D-1)

$(M_{Flex\_Axial})_{Heel} := Check\left(Mu_{heel}, \phi M_{n.Heel}\right) = [\text{“OK”} \quad 0.4]$

Minimum Required Steel for Flexure

Given

Constraints

Values

$As_{req} := 1.5\ in^2$

$Mu_{heel} = \phi_b \cdot \left(\left(As_{req} \cdot (F_y)_{60} \cdot \left(d_{heel.top} - \frac{As_{req} \cdot (F_y)_{60} + (P_u)_{heel} \cdot b}{0.85 \cdot f'_c \cdot d_{heel.top}}\right)\right) - \left((P_u)_{heel} \cdot \left(d_{heel.top} - \frac{TTOE}{2}\right) \cdot b\right)\right)$

Solver

$As_{req.stem} := \text{find}\left(\mathbf{As_{req}}\right) = 0.201\ in^2$

(minimum steel required for flexural strength)

$(A_{s.min})_{heel.top} := As_{req.stem} = 0.2\ in^2$

Minimum Required Steel per ACI

$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.825\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.82\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

temperature and shrinkage reinforcement

Heel - Top Reinforcement

$(d_b)_{heel.top} = 1\ in$ *bars located at* $s_{heel.top} = 12\ in$ *centers*

Heel - Lateral Reinforcement

$(d_b)_{heel.lat} = 0.75\ in$ *bars located at* $s_{heel.lat} = 12\ in$ *centers*

Heel - Bottom Reinforcement

Reference above calculations for the bottom steel from the toe design, toe steel is transferred through the base into the heel.

Heel - Bottom Lateral Reinforcement

Reference above calculations for the bottom steel from the toe design, toe steel is transferred through the base into the heel.

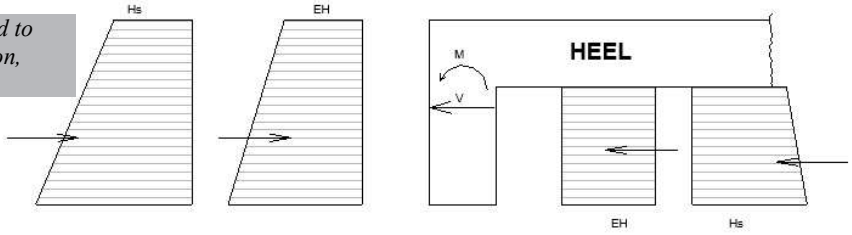
KEY DESIGN

Loads to Key

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last

$HK = 3.5\ ft$ *(depth of key, from bottom of foundation down)*

$THEEL = 5.5\ ft$ *(depth of key, from top of foundation down)*



Hydrostatic Loads - Front of Key

Note: hydrostatic loads applied in two directions, notated as fk = front of key and bk = back of key

$(\sigma_{Hs})_{fk1} := \gamma_{water} \cdot (HTS + TTOE) = 0.749\ ksf$ *(horizontal water loading, top of key)*

$(\sigma_{Hs})_{fk2} := \gamma_{water} \cdot (HTS + THEEL) = 0.967\ ksf$ *(horizontal water loading, bottom of key)*

$(Hs)_{fk} := \frac{HK \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})}{2} = 3\ klf$ *(hydrostatic loading to the front of key)*

$(x_{Hs})_{fk} := \frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{fk2}) + (\sigma_{Hs})_{fk1})}{3 \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})} = 1.82\ ft$ *(moment arm for hydrostatic loading, measured down from key connection to foundation)*

Hydrostatic Loads - Back of key

$(\sigma_{Hs})_{bk.top} := (\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.756 \\ 0.883 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bk.bot} := (\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.809 \\ 0.959 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(Hs)_{bk} := \frac{HK \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{2} = \begin{bmatrix} 2.7 \\ 3.2 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of the key)*

$(x_{Hs})_{bk} := \left(\frac{HK \cdot (2 \cdot (\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{3 \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})} \right) = \begin{bmatrix} 1.8 \\ 1.8 \end{bmatrix} ft$ *(moment arm of the hydrostatic loading to the front face of the key, measured down from the connection to foundation)*

Lateral Earth Pressures - Face of Key

$(\sigma_{EH})_{fk.top} := \gamma'_{soil} \cdot k_0 \cdot (HTS + TTOE) = 0.367\ ksf$ *(min horizontal lateral earth loading, top of foundation)*

$(\sigma_{EH})_{fk.bot} := \gamma'_{soil} \cdot k_0 \cdot (HTS + THEEL) = 0.474\ ksf$ *(min horizontal lateral earth loading, bottom of foundation)*

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(EH)_{fk} := \frac{HK \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{2} = 1.5\ klf$ *(resultant of the lateral earth loading to the front face of key)*

$(x_{EH})_{fk} := \frac{HK \cdot (2 \cdot (\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{3 \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})} = 1.824\ ft$ *(moment arm of the lateral earth loading to to the front face of the key, measured from the the connection of the key to the foundation)*

Lateral Earth Pressures - Back of Key

$(\sigma_{EH})_{bk.top} := (\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.202 \\ 1.007 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bk.bot} := (\sigma_{EH})_{bh.bot} = \begin{bmatrix} 1.202 \\ 1.007 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(EH)_{bk} := \frac{HK \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{2} = \begin{bmatrix} 4.2 \\ 3.5 \end{bmatrix} klf$ *(resultant of the lateral earth loading to the back face of key)*

$(x_{EH})_{bk} := \frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{3 \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)} = \begin{bmatrix} 1.8 \\ 1.8 \end{bmatrix} ft$ *(moment arm for the lateral earth loading to the back face of the key, measured from the connection of the key to the foundation)*

Resultant Moment - on Toe

$LC1_{fk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{fk} \cdot (x_{EH})_{fk}}\right) + \left(\overrightarrow{(Hs)_{fk} \cdot (x_{Hs})_{fk}}\right)\right) = 13.1 \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{bk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{bk} \cdot (x_{EH})_{bk}}\right) + \left(\overrightarrow{(Hs)_{bk} \cdot (x_{Hs})_{bk}}\right)\right) = \begin{bmatrix} 19.5 \\ 19 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$LC1_{key} := LC1_{bk} - LC1_{fk} = \begin{bmatrix} 6.5 \\ 6 \end{bmatrix} \frac{kip \cdot ft}{ft}$

$Mu_{key} := \max\left(LC1_{bk} - LC1_{fk}\right) \cdot 1\ ft = 6.5\ kip \cdot ft$ *(factored maximum moment at connection of floodwall key to the heel)*

Key Reinforcement

Back Bars - Main Steel

$(d_b)_{key.main} :=$ Bar Size: #8 $= 1\ in$ *(main bar size in key)*

$s_{key.main} := 12\ in$ *(main bar spacing in key)*

$c_{key.main} :=$ 4″ cover *(cover for main reinforcement in key)*

$(A_s)_{key.main} := \frac{0.25 \cdot \pi \cdot (d_b)_{key.main}^{\ 2} \cdot 12\ in}{s_{key.main}} = 0.785\ in^2$ *(area of steel for top reinforcement in key)*

$d_{key.main} := TTOE - c_{key.main} - 0.5 \cdot (d_b)_{key.main} = 19.5\ in$ *(depth to main reinforcement in key)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{key.main} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot \left(f'_c - 4000\ psi\right)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.8$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

Key reinforcement in back of key same as front of key

U.S.ARMY CORPS OF ENGINEERS - KANSAS CITY DISTRICT

T-Wall Load Cases and Strength Design

Upper Turkey Creek

Merriam, KS

ASSUMPTIONS

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

FLOOD LOAD CASES

Unusual Case

Top of Wall, ACE = 100 year event, Unusual Case

WSE = Top of Protection

Usual Case

ACE = 10 year event, Usual Case

WSE elevation below the top of the foundation

Note: The Unusual Flood Case with water to the top of the wall governs the design of this floodwall. Non-flood condition loads such as construction, seismic and wind are addressed in the stem design; however, it is apparent that the top of wall flood condition governs stability and the primary steel design so only the Unusual top of wall flood load is considered for stability and the base design.

The Usual Flood Case does not have water to the top of the foundation and is not included in these calculations.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$\gamma'_{soil} := \gamma_{soil} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$q_n := 2000\ psi$ *(bearing pressure, Reference DDR Table 9.2)*

Drained Soil Conditions

$\phi_{drained} := 28\ deg$ *(internal friction angle for drained soil condition)*

$C_{drained} := 0\ psf$ *(cohesion for drained soil condition)*

$k_0 := 1 - \sin\left(\phi_{drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

Undrained Soil Conditions

$\phi_{undrained} := 0\ deg$ *(internal friction angle for drained soil condition)*

$C_{undrained} := 1000\ psf$ *(cohesion for drained soil condition)*

$(k_0)_{undrained} := 1 - \sin\left(\phi_{undrained}\right) = 1$ *(at-rest soil pressure coefficient for the undrained condition)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(young's modulus of elasticity for steel)*

$(F_y)_{30} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$(F_y)_{60} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$\varepsilon_{ty} := \frac{(F_y)_{60}}{E_{steel}} = 0.0021$ *(yield strain of 60 ksi steel)*

Concrete Properties

$f'_c := 4500\ psi$ *(concrete compressive strength for all structures)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength for all structures)*

$q\lambda_c := 1.0$ *(concrete modification factor)*

$cover_3 := 3\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$cover_4 := 4\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$\gamma_{conc} := 150\ pcf$ *(concrete unit weight)*

$Ec := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$ *(young's modulus of elasticity for concrete)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

Load Factors

Serviceability Load Factors

Note: the unusual loading condition is used for the top of the floodwalls since they are designed to the 100 year event. the usual loading condition is defined as the 10 year event.

$(\gamma_p)_{Serve.u} := 2.2$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

$(\gamma_p)_{Serve.n} := 1.6$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

Strength Limit States

$\phi_b := 0.9$ *(bending load reduction factor - ACI 318-19 21.2.2, Table 21.2.2)*

$\phi_A := 0.9$

$\phi_V := 0.75$ *(shear load reduction factor - ACI 318-19 Table 21.2.1)*

CT WALL DATA

Input Data - Drained

$ELTS := 920.31\ ft$

$HTS := 10\ ft$

$TTS := 1.5\ ft$

$TBS := 1.5\ ft$

$THEEL := 5.5\ ft$

$TTOE := 2\ ft$

$TWIDTH := 2.5\ ft$

$BWIDTH := 13\ ft$

$HK := 3.5\ ft$

$TK := 3\ ft$

$Elev_{soil.d} := 912\ ft$ *(driving side soil elevation)*

$Elev_{soil.r} := 912\ ft$ *(resisting side soil elevation)*

$ELTF := ELTS - HTS = 910.3\ ft$ *(calculated top of foundation elevation)*

$ELTK := ELTF - THEEL + HK = 908.3\ ft$ *(calculated top of key, bottom of foundation elevation)*

$HSD := Elev_{soil.d} - ELTF = 1.7\ ft$ *(calculated depth of soil, driving side)*

$HSR := Elev_{soil.r} - ELTF = 1.7\ ft$ *(calculated depth of soil, resisting side)*

DRAINED CASE

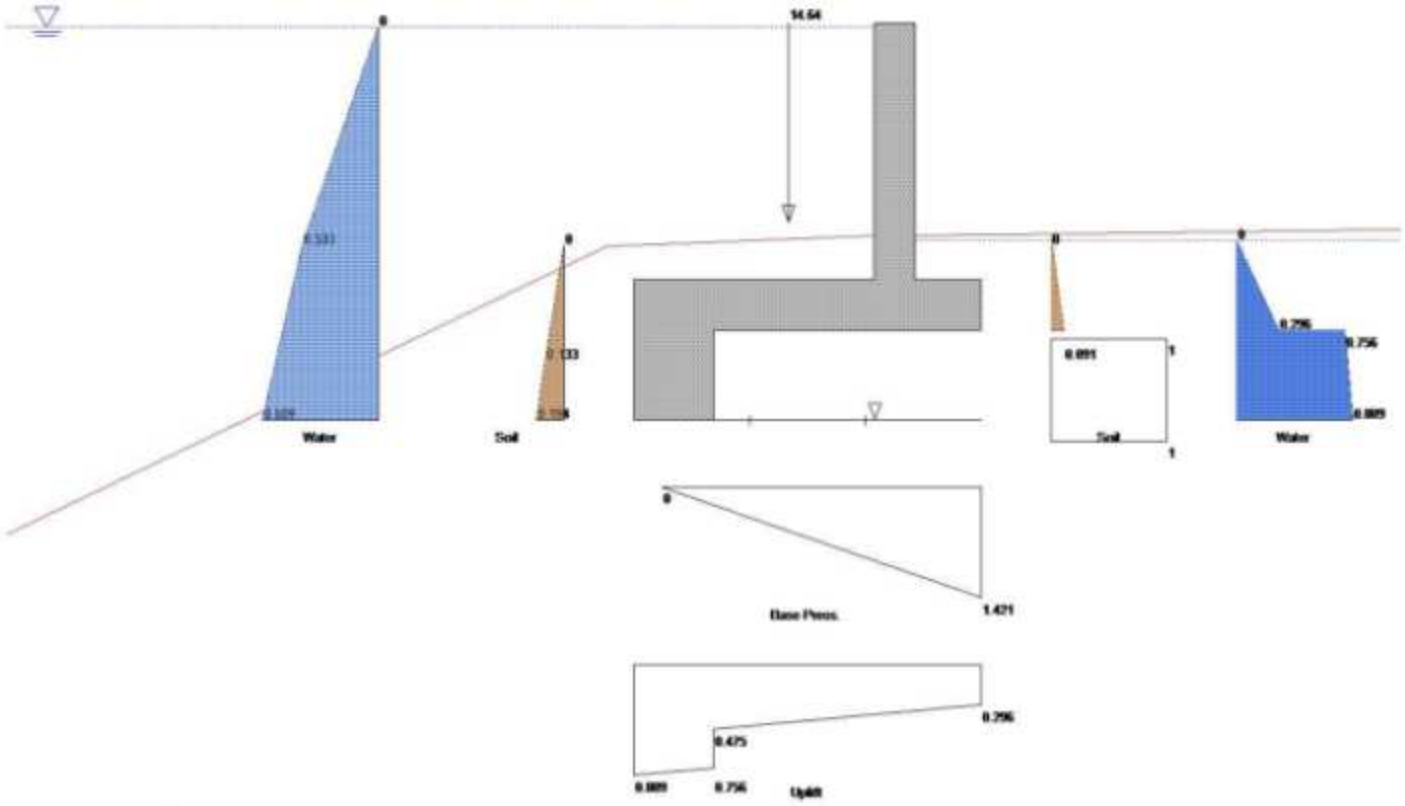
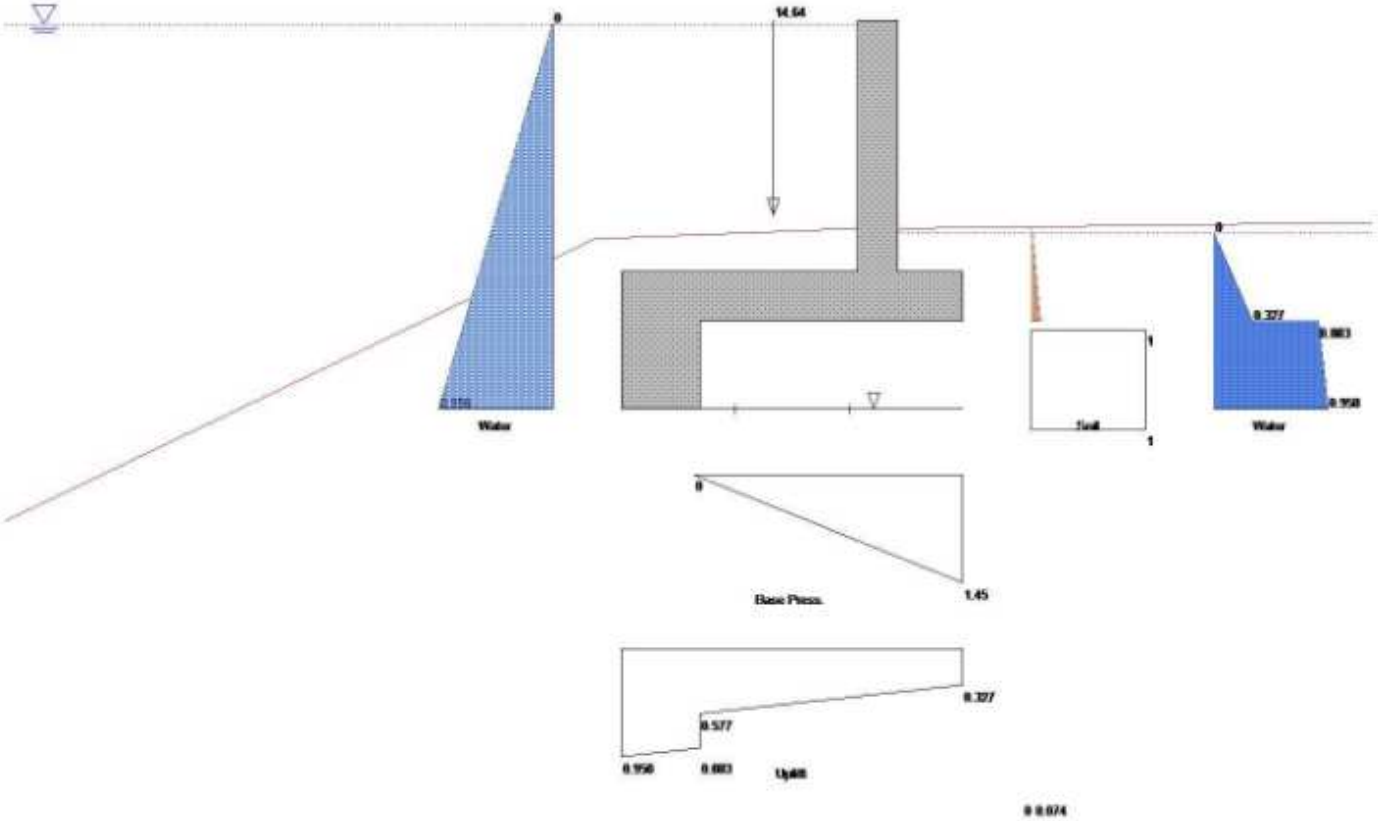
CT Wall - Drained Case Output



CT Wall - Undrained Case Output



CTWALL OUTPUT

Lateral Earth Loading

$\sigma_{EHd} := \begin{bmatrix} 0.194 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side, bottom of key; Drained, Undrained)*

$\sigma_{EHr} := \begin{bmatrix} 0.0906 \\ 0.074 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side, bottom of foundation at toe; Drained, Undrained)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} := \begin{bmatrix} 1.202 \\ 1.007 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation; Drained, Undrained)*

$(\sigma_{EH})_{bh.bot} := \begin{bmatrix} 1.202 \\ 1.007 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key, Drained, Undrained)*

Impact Loading

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

Soil Pressure

$(\sigma_{SP})_{max} := -\begin{bmatrix} 1.421 \\ 1.45 \end{bmatrix} ksf$ *(max base soil loading from CT Wall Output)*

Uplift Pressure

$UL_1 := \begin{bmatrix} 0.809 \\ 0.958 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 0.756 \\ 0.883 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.475 \\ 0.577 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.296 \\ 0.327 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$(\sigma_{UL})_{min} := UL_4 = \begin{bmatrix} 0.296 \\ 0.327 \end{bmatrix} ksf$ *(minimum uplift pressure at the end of the toe)*

$(\sigma_{UL})_{max} := UL_3 = \begin{bmatrix} 0.475 \\ 0.577 \end{bmatrix} ksf$ *(maximum uplift pressure behind the key)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} := \begin{bmatrix} 0.756 \\ 0.883 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

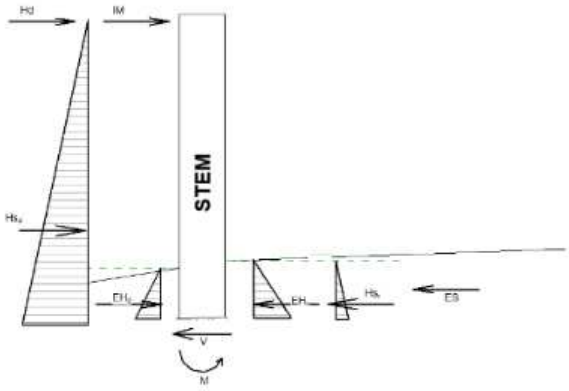
$(\sigma_{Hs})_{bh.bot} := \begin{bmatrix} 0.809 \\ 0.959 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

STEM DESIGN, RIVER SIDE

Loads to Stem

Note: largest loading from drained and undrained cases used to determine the controlling load case. In each loading condition, drained loads are listed first and undrained last.

This design for the riverside steel, along with the EnerCalc calculations, attached will be used for the landside steel design for simplicity. By inspection, the riverside reinforcement is sufficient for the landside reinforcement design.



Hydrostatic Loads

$\sigma_{Hsd} := \begin{bmatrix} \gamma_{water} \cdot HTS \\ \gamma_{water} \cdot HTS \end{bmatrix} = \begin{bmatrix} 624 \\ 624 \end{bmatrix} psf$ *(hydrostatic pressure loading to driving side)*

$Hs_d := \overrightarrow{0.5 \cdot \sigma_{Hsd} \cdot HTS} = \begin{bmatrix} 3.12 \\ 3.12 \end{bmatrix} klf$ *(hydrostatic loading to driving side)*

$(x_{Hs})_d := HTS \cdot \frac{1}{3} = 3.3\ ft$ *(moment arm for hydrostatic loading to the driving side from the base of the stem)*

Note: assume that hydrostatic loading from the resisting side of the T-wall provided from groundwater up to the ground surface. Assume that all additional water from the resisting side, landside, of the floodwall is conveyed away through interior drainage systems.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 105.5 \\ 105.5 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{0.5 \cdot \sigma_{Hsr} \cdot HSR} = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(hydrostatic loading to resisting side)*

$(x_{Hs})_r := HSR \cdot \frac{1}{3} = 0.56\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Lateral Earth Loading

$(\sigma_{EHd})_{stem} := \sigma_{EHd} \cdot \left(\frac{HSD}{HSD + THEEL} \right) = \begin{bmatrix} 0.046 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side of stem)*

$EH_d := \overrightarrow{0.5 \cdot (\sigma_{EHd})_{stem} \cdot HSD} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to driving side of stem)*

$(x_{EH})_d := HSD \cdot \frac{1}{3} = 0.6\ ft$ *(moment arm for lateral earth loading to the driving side from the base of the stem)*

$(\sigma_{EHr})_{stem} := \sigma_{EHr} \cdot \frac{HSR}{HSR + TTOE} = \begin{bmatrix} 0.041 \\ 0.034 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side of stem)*

$EH_r := \overrightarrow{0.5 \cdot (\sigma_{EHr})_{stem} \cdot HSR} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to resisting side of stem)*

$(x_{EH})_r := HSR \cdot \frac{1}{3} = 0.6\ ft$ *(moment arm for lateral earth loading to the resisting side from the base of the stem)*

Impact Loading

Note: reference DDR for discussion of impact loading on floodwalls.

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

$(x_{IM})_d := HTS = 10\ ft$ *(moment arm of the impact load from the base of the stem)*

Operating Equipment

$p_{const} := 250\ psf$ *(construction surcharge loading)*

Note: assume that the surcharge loading is uniform and that the resultant is mid-height of the soil depth.

$d_{soil} := HSR = 1.7\ ft$ *(depth of soil cover on stem)*

$(x_Q)_d := \frac{HSR}{2} = 0.8\ ft$ *(resultant height above base of stem)*

$x_Q := d_{soil} - (x_Q)_d = 0.8\ ft$ *(depth from resultant to top of soil)*

$\sigma_H := p_{const} \cdot k_0 = 0.133\ ksf$ *(lateral linear pressure applied to wall)*

$Q := \sigma_H \cdot HSR = 0.224\ klf$ *(lateral surcharge load to structure, usual case)*

Wind

Note: for conservative analysis, wind loading only applied to the driving side as a positive pressure or applied to the resisting side as a negative pressure.

$(p_w)_p := 30.4\ psf$ *(primary wind pressure, reference DDR)*

$(p_w)_c := 15.8\ psf$ *(companion wind pressure, reference DDR)*

$G := 0.85\ \frac{1}{ft}$ *(gust factor, ASCE 7-16 Section 26.11.1)*

$C_f := 1.3$ *(force coefficient from ASCE 7-16, figure 29.3-1, s/h = 1 and B/s = '>45')*

$d := HTS - HSR = 8.3\ ft$ *(exposed surface of the stem for wind pressure)*

$A_s := 1\ ft \cdot d = 8.3\ ft^2$ *(exposed surface area of the wall per linear foot)*

$W_c := (p_w)_c \cdot G \cdot C_f \cdot A_s = 0.145\ klf$ *(wind loading, usual case for companion loading)*

$W_p := (p_w)_p \cdot G \cdot C_f \cdot A_s = 0.279\ klf$ *(wind loading, unusual case)*

$(x_W)_d := HTS - \frac{d}{2} = 5.8\ ft$ *(resultant height above base of stem)*

Earthquake Loading: Equivalent Lateral Force

$D_{wall} := (TTS \cdot HTS) \cdot \gamma_{conc} = 2.3\ \frac{1}{ft} \cdot kip$ *(dead load of the stem of the wall)*

$I_e := 1.5$ *(importance factor, ASCE 7-16 Table 1.5-2)*

$R := 2.5$ *(response modification factor, ASCE 7-16, Table 12.2-1, Item G.3)*

$S_{DS} := 0.101$ *(seismic spectral acceleration for short period)*

$Cs := \frac{S_{DS}}{\frac{R}{I_e}} = 0.1$ *(seismic response coefficient, ASCE 7-16 12.8-2)*

$V := Cs \cdot D_{wall} = 0.1\ klf$ *(seismic base shear, ASCE 7-16, EQ 12.8-1)*

$EQ := V = 0.1\ klf$

$(x_{EQ}) := HSR = 1.7\ ft$ *(resultant height above base of stem)*

Load Combinations

Note: Usual design cases not considered here as the Usual pool level does not reach the base of the stem.

Driving Side Forces

$LC1_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Hs_d + IM) = \begin{bmatrix} 5.2 \\ 5.2 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot (EH_d + EQ) = \begin{bmatrix} 0.3 \\ 0.2 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Q) = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} klf$ *(load case 3 for construction)*

Resisting Side Forces

$LC1_r := (\gamma_p)_{Serve.n} \cdot (EH_r + Hs_r - W_c) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix} klf$ *(load case 4 for construction)*

Resultant Shear at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 5.2 \\ 5.2 \end{bmatrix} klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix} klf$ *(equilibrium load case 3)*

$\Sigma F_{stem} := \text{stack}(LC1, LC2, LC3)$

Note: Maximum factored shear loading to the stem is the governing loading for the river side steel design. Minimum factored shear loading is the governing landside steel design.

$(Vu)_{stem} := \max(\Sigma F_{stem}) = 5.2\ klf$ *(resultant factored shear at base of floodwall stem, driving side)*

Resultant Moment - Driving Side

$LC1_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Hs_d \cdot (x_{Hs})_d \right) + IM \cdot (x_{IM})_d \right) = \begin{bmatrix} 18.3 \\ 18.2 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(EQ \cdot (x_{EQ}) \right) \right) = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Q \cdot \left((x_Q)_d \right) \right) \right) = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction)*

Resultant Moment - Resisting Side

$LC1_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) + \left(Hs_r \cdot (x_{Hs})_r \right) \right) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum flooding)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction or surcharge loading)*

Resultant Moment at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 18.2 \\ 18.1 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 3)*

$\Sigma M_{stem} := \text{stack}(LC1, LC2, LC3)$ *(resultant factored moment at base of floodwall stem)*

$(Mu)_{stem} := \max(\Sigma M_{stem}) \cdot 1\ ft = 18.2\ kip \cdot ft$ *(resultant moment at base of floodwall stem, riverside steel design)*

Design Check Function

(system check for capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing arrays)

$$Check_v\left(X_U, X_N\right) := \left\| \begin{array}{l} \text{for } i \in \mathbf{ORIGIN} .. \text{last}\left(X_U\right) \\ \quad \left\| \begin{array}{l} \text{if } X_{U_i} > X_{N_i} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“NO GOOD”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \\ \text{else if } X_{N_i} = 0 \\ \quad \left\| ch_{i,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“OK”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing scalar values)

$$Check\left(X_U, X_N\right) := \left\| \begin{array}{l} \text{if } X_U > X_N \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“NO GOOD”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ \text{else if } X_U = 0 \\ \quad \left\| ch_{1,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“OK”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

$b := 12\ in$ *(strip width for analysis)*

Stem Reinforcement

Vertical Bars

$(d_b)_{stem.vert} :=$ Bar Size: #8 $= 1\ in$ *(vertical bar size in stem)*

$s_{stem.vert} := 12\ in$ *(vertical bar spacing in stem)*

$c_{stem.vert} :=$ 3″ cover *(cover for vertical reinforcement in stem)*

$$(A_s)_{stem.vert} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.vert}^{\ 2} \cdot b}{s_{stem.vert}} = 0.785\ in^2$$ *(area of steel vertical reinforcement in stem)*

$d_{stem.vert} := TTS - c_{stem.vert} - \left(0.5 \cdot (d_b)_{stem.vert}\right) = 14.5\ in$ *(depth to reinforcement vertical reinforcement in stem)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{stem} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$$a_{stem.vert} := \frac{(A_s)_{stem.vert} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}} = 0.85\ in$$

(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)

$$(\phi M_n)_{stem.vert} := \phi_b \cdot (A_s)_{stem.vert} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{a_{stem.vert}}{2}\right) = 49.7\ kip \cdot ft$$

(nominal flexural strength, EM1110-2-2104, B-49)

$$(Flex_{nom})_{Stem} := Check\left((Mu)_{stem}, (\phi M_n)_{stem.vert}\right) = [\text{"OK"} \quad 0.37]$$

(nominal flexural check, with Utilization ratio)

Minimum Required Steel for Flexure

Solve Constraints Given Values

$$As_{req} := 1.5\ in^2$$

$$(Mu)_{stem} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$$

$$As_{req.stem} := \mathbf{find}\left(\mathbf{As_{req}}\right) = 0.284\ in^2$$

$$(A_{s.min})_{stem.ten} := As_{req.stem} = 0.284\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.584\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.58\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTS \cdot b) = 0.324\ in^2$$

(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$

(minimum area of steel required for flexural capacity)

$$A_{s.min} = 0.584\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{stem.ten} \cdot \frac{4}{3} = 0.379\ in^2$$

(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)

$$(A_s)_{stem.req} := \begin{cases} as \leftarrow (A_{s.min})_{stem.ten} & \text{if } A_{s\_1.3} < (A_s)_{stem.vert} \\ as \leftarrow A_{s.min} & \text{else} \end{cases} = 0.284\ in^2$$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{stem.vert} = 0.8\ in^2$$

(area of steel provided in the vertical direction for the stem)

$$(Steel\_Check_{Vert})_{Stem} := Check\left((A_s)_{stem.req}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$$

(check stem reinforcement to required reinforcement)

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Vert.ts})_{Stem} := Check\left((A_{s.min})_{temp}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$ *(check stem reinforcement to temperature and shrinkage requirements)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{stem.vert}}{\left(b \cdot d_{stem.vert}\right)} = 0.0045$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{Stem} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{stem.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in stem)*

$s_{stem.lat} := 12\ in$ *(lateral bar spacing in stem)*

$(A_s)_{stem.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.lat}^{\ 2} \cdot 12\ in}{s_{stem.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in stem)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot \left(TTS \cdot b\right)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.3\ in^2$

$(A_s)_{stem.lat} = 0.4\ in^2$ *(area of steel provided in the lateral direction for the stem)*

$(Steel\_Check_{Lat})_{Stem} := Check\left(A_{s.req}, (A_s)_{stem.lat}\right) = [\text{"OK"} \quad 0.7]$ *(check stem reinforcement to required reinforcement)*

Riverside Reinforcement

Primary Reinforcement

$(d_b)_{stem.vert} = 1\ in$ *bars located at* $s_{stem.vert} = 12\ in$ *centers*

Lateral Reinforcement

$(d_b)_{stem.lat} = 0.75\ in$ *bars located at* $s_{stem.lat} = 12\ in$ *centers*

Deflection Check

Note: Reference provided justification file for loading conditions and attached EnerCalc calculations for the deflections in floodwall stem since stem thickness is less than H/8. From EnerCalc report, wall deflections limited to H/6838, which is less than expected movement capacity in waterstop and wall joints. 10 ft tall floodwalls to have stems with above detailed reinforcement.

Landside Reinforcement

For design simplicity, landside reinforcement to match both primary and lateral reinforcement.

STEM SHEAR CONNECTION TO FOUNDATION

Shear Friction

$f_y := (F_y)_{60} = 60000\ psi$ *(yield strength of reinforcing steel)*

$\mu := 1.0$

$(d_b)_{stem.vert.2} :=$ Bar Size: #6 $= 0.75\ in$ *(vertical bar size in stem)*

$s_{stem.vert2} := 12\ in$

$A_{vf} := \left(\frac{\pi}{4}\right) \cdot (d_b)_{stem.vert.2}{}^2 \cdot \left(\frac{b}{s_{stem.vert2}}\right) = 0.4\ in^2$

$V_n := \mu \cdot A_{vf} \cdot f_y = 26.5\ kip$ *(shear-friction strength, ACI 318-19, eq 22.9.4.2)*

Table 22.9.4.2—Coefficients of friction

Contact surface condition	Coefficient of friction μ[1]	
Concrete placed monolithically	1.4λ	(a)
Concrete placed against hardened concrete that is clean, free of laitance, and intentionally roughened to a full amplitude of approximately 1/4 in.	1.0λ	(b)
Concrete placed against hardened concrete that is clean, free of laitance, and not intentionally roughened	0.6λ	(c)
Concrete placed against as-rolled structural steel that is clean, free of paint, and with shear transferred across the contact surface by headed studs or by welded deformed bars or wires.	0.7λ	(d)

[1]λ = 1.0 for normalweight concrete. For lightweight concrete, λ is calculated as given in 19.2.4, but shall not exceed 0.85.

Maximum Shear Friction

$A_c := b \cdot TTS = 1.5\ ft^2$

$(V_n)_a := 0.2\ f'_c \cdot A_c = 194.4\ kip$ *(shear-friction maximum, equation a, Table 22.9.4.4)*

$(V_n)_b := \left(480\ psi + 0.08 \cdot f'_c\right) \cdot A_c = 181.4\ kip$ *(shear-friction maximum, equation b, Table 22.9.4.4)*

$(V_n)_c := \left(16000\ psi\right) A_c = 3456\ kip$ *(shear-friction maximum, equation c, Table 22.9.4.4)*

Table 22.9.4.4—Maximum V_n across the assumed shear plane

Condition	Maximum V_n		
Normalweight concrete placed monolithically or placed against hardened concrete intentionally roughened to a full amplitude of approximately 1/4 in.	Least of (a), (b), and (c)	$0.2f'_cA_c$	(a)
		$(480 + 0.08f'_c)A_c$	(b)
		$1600A_c$	(c)
Other cases	Lesser of (d) and (e)	$0.2f'_cA_c$	(d)
		$800A_c$	(e)

$(V_n)_{max} := \max\left((V_n)_a, (V_n)_b, (V_n)_c\right) = 3456\ kip$ *(shear-friction maximum, Table 22.9.4.4)*

Shear Strength

$\phi_V = 0.75$ *(reduction factor for shear capacity)*

$\phi_V V_n := \phi_V \cdot min\left((V_n)_{max}, V_n\right) = 19.9\ kip$ *(factored shear-friction strength)*

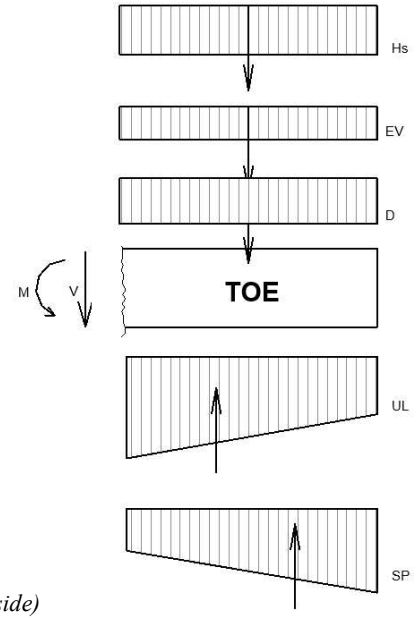
$V_{stem} := (Vu)_{stem} \cdot b = 5.2\ kip$ *(calculated shear required at base of stem)*

$V_{check} := Check\left(V_{stem}, \phi_V V_n\right) = [\text{"OK"} \quad 0.3]$ *(shear check, utilization ratio)*

Toe Check

Loads to Toe

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



Dead Load

$\sigma_D := \gamma_{conc} \cdot TTOE = 300\ psf$

$D := \sigma_D \cdot TWIDTH = 0.8\ klf$ *(resultant dead load of toe)*

$(x_D)_{toe} := \frac{TWIDTH}{2} = 1.3\ ft$ *(moment arm of the dead loading from the connection of the toe to the foundation)*

Hydrostatic Loads Above Toe

Note: Groundwater assumed to the soil surface. Potential additional seepage pressure conservatively ignored.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 105.5 \\ 105.5 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{TWIDTH \cdot \sigma_{Hsr}} = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} klf$ *(Resultant hydrostatic loading to resisting side)*

$(x_{Hs})_r := TWIDTH \cdot 0.5 = 1.25\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Vertical Earth Pressure

$\sigma_{EV} := \gamma'_{soil} \cdot HSR = 97.3\ psf$

$EV_r := \begin{bmatrix} \sigma_{EV} \cdot TWIDTH \\ \sigma_{EV} \cdot TWIDTH \end{bmatrix} = \begin{bmatrix} 0.243 \\ 0.243 \end{bmatrix} klf$ *(buoyant force of vertical soil loading)*

$(x_{EV})_r := \frac{TWIDTH}{2} = 1.3\ ft$

Soil Pressure

$(\sigma_{SP})_{max} = \begin{bmatrix} -1.421 \\ -1.45 \end{bmatrix} ksf$ *(max soil loading from CT Wall Output)*

$BWIDTH = 13\ ft$ *(total length of base of wall)*

$BIC_{percent} := \begin{bmatrix} 89.61 \\ 75.35 \end{bmatrix}\%$ *(percent of the base in compression)*

$BIC := BWIDTH \cdot BIC_{percent} = \begin{bmatrix} 11.6 \\ 9.8 \end{bmatrix} ft$ *(length of base in compression)*

$TWIDTH = 2.5\ ft$ *(length of toe of the foundation)*

note: using the length of the toe to determine the soil loading at the the connection of the toe to the stem and heel, use similar triangles to determine the loading at the connection of the toe.

$NTWIDTH := BIC - TWIDTH = \begin{bmatrix} 9.1 \\ 7.3 \end{bmatrix} ft$ *(length of the not-toe of the foundation in compression)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{NTWIDTH}{(\sigma_{SP})_1}$ *(relationship of similar triangles)*

$(\sigma_{SP})_1 := \overrightarrow{NTWIDTH \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} -1.12 \\ -1.08 \end{bmatrix} ksf$ *(soil pressure loading at the connection of the toe)*

$SP_{toe} := \frac{TWIDTH \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)}{2} = \begin{bmatrix} -3.2 \\ -3.2 \end{bmatrix} klf$ *(resultant soil loading to the toe of the foundation)*

$$(x_{SP})_{toe} := \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{SP})_{max}\right) + (\sigma_{SP})_1\right)}{3 \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)} = \begin{bmatrix} 1.3 \\ 1.3 \end{bmatrix} ft$$

(moment arm from the connection of the toe to the resultant of the soil pressure loading)

Uplift Pressures

$$(\sigma_{UL})_{min} = \begin{bmatrix} 0.296 \\ 0.327 \end{bmatrix} ksf$$

(minimum uplift pressure at the end of the toe)

$$(\sigma_{UL})_{max} = \begin{bmatrix} 0.475 \\ 0.577 \end{bmatrix} ksf$$

(maximum uplift pressure behind the key)

Note: Uplift pressure drops off linearly from the back of the key to the toe of the foundation

$BWIDTH = 13\ ft$ *(foundation width)*

$TK = 3\ ft$ *(key width)*

$L := BWIDTH - TK = 10\ ft$ *(length of linear uplift pressure)*

$(\sigma_{UL})_{max} - (\sigma_{UL})_{min} = m(L)$ *(linear relationship)*

$$m := \frac{(\sigma_{UL})_{max} - (\sigma_{UL})_{min}}{L} = \begin{bmatrix} 0.0179 \\ 0.025 \end{bmatrix} \frac{ksf}{ft}$$

(linear relationship)

$$(\sigma_{UL})_{max.toe} := \overrightarrow{(m \cdot TWIDTH) + (\sigma_{UL})_{min}} = \begin{bmatrix} 0.341 \\ 0.39 \end{bmatrix} ksf$$

(uplift pressure at the connection of the toe to the foundation)

$$UL_{toe} := \frac{-TWIDTH \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)}{2} = \begin{bmatrix} -0.8 \\ -0.9 \end{bmatrix} klf$$

(uplift pressure resultant for the toe of the foundation)

$$(x_{UL})_{toe} := TWIDTH - \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{UL})_{max.toe}\right) + (\sigma_{UL})_{min}\right)}{3 \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)} = \begin{bmatrix} 1.2 \\ 1.2 \end{bmatrix} ft$$

(distance from the connection of the toe to the resultant of the uplift pressure)

Load Combinations

Resisting Side Forces - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \left(D + EV_r + Hs_r + SP_{toe} + UL_{toe}\right) = \begin{bmatrix} -4.3 \\ -4.5 \end{bmatrix} klf$$

(load case 1 for infrequent flooding)

$$\Sigma F_{toe} := \max\left(\overrightarrow{|LC1|}\right) = 4.5\ klf$$

(maximum of the drained vs undrained cases)

Factored Shear on Toe at Face of Stem

$$(V_u)_{toe} := \Sigma F_{toe} = 4.5\ klf$$

(maximum factored shear in toe)

Resultant Moment - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(D \cdot (x_D)_{toe}\right) + \left(\overrightarrow{Hs_r \cdot (x_{Hs})_r}\right) \\ + \left(\overrightarrow{EV_r \cdot (x_{EV})_r}\right) + \left(\overrightarrow{SP_{toe} \cdot (x_{SP})_{toe}}\right) \\ + \left(\overrightarrow{UL_{toe} \cdot (x_{UL})_{toe}}\right) \end{pmatrix} = \begin{bmatrix} -5.6 \\ -5.9 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case 1 for infrequent flooding)

Maximum Factored Moment in Toe at Face of Stem

$$Mu_{toe} := \max(LC1) \cdot 1\ ft = -5.6\ kip \cdot ft$$

(resultant moment at base of floodwall stem per foot of wall)

$$Mu_{toe} := -Mu_{toe}$$

Toe Reinforcement

Bottom Bars - Main Steel

$(d_b)_{toe.bot} := \text{Bar Size: \#8} = 1\ in$ *(bottom bar size in toe)*

$s_{toe.bot} := 12\ in$ *(bottom bar spacing in toe)*

$c_{toe.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in toe)*

$(A_s)_{toe.bot} := \dfrac{0.25 \cdot \pi \cdot (d_b)_{toe.bot}^{\ 2} \cdot b}{s_{toe.bot}} = 0.785\ in^2$ *(area of steel for bottom reinforcement in toe)*

$d_{toe.bot} := TTOE - c_{toe.bot} - \left(0.5 \cdot (d_b)_{toe.bot}\right) = 19.5\ in$ *(depth to reinforcement bottom reinforcement in toe)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{toe.bot} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\dfrac{0.05 \cdot \langle f'_c - 4000\ psi \rangle}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$a_{toe.bot} := \dfrac{(A_s)_{toe.bot} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{toe.bot}} = 0.6\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)*

$(\phi M_n)_{toe.bot} := \phi_b \cdot (A_s)_{toe.bot} \cdot (F_y)_{60} \cdot \left(d_{toe.bot} - \dfrac{a_{toe.bot}}{2}\right) = 67.8\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{toe} := Check\left(Mu_{toe}, (\phi M_n)_{toe.bot}\right) = [\text{“OK”} \quad 0.08]$ *(nominal flexural check)*

Minimum Required Steel for Flexure

Solve Constraints Values

$As_{req} := 1.5\ in^2$

$Mu_{toe} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \dfrac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$

$(As_{req})_{toe} := \text{find}\left(As_{req}\right) = 0.1\ in^2$ *(minimum required reinforcement for flexural strength)*

Minimum Required Steel per ACI

$(A_{s.min})_a := \dfrac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.785\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \dfrac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.8\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.785\ in^2$

$A_{s\_1.3} := (As_{req})_{toe} \cdot \frac{4}{3} = 0.1\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

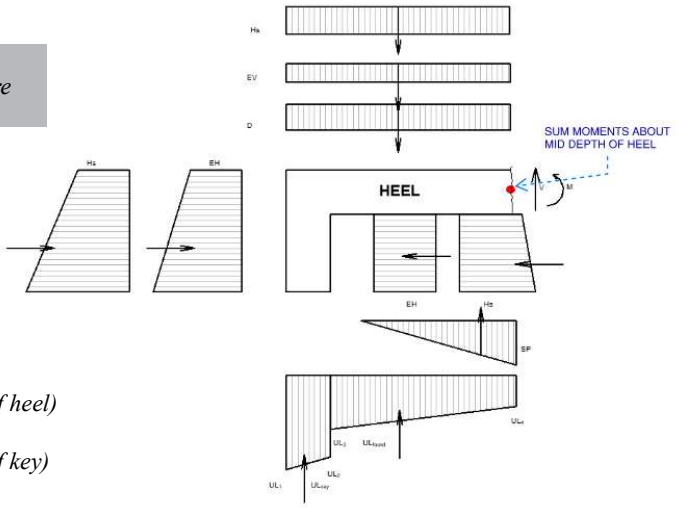
Toe - Top Lateral Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

HEEL DESIGN

Loads to Heel

Note: largest loading from drained and undrained cases used to create conservative design for loading. In each loading condition, drained loads are listed first and undrained last



$HWIDTH := BWIDTH - TTS - TWIDTH = 9\ ft$

(Length of heel, includes key)

Dead Load

$(\sigma_D)_{Heel} := \gamma_{conc} \cdot (TTOE) = 300\ psf$

$(\sigma_D)_{Key} := \gamma_{conc} \cdot (HK) = 525\ psf$

$D_{Heel} := (\sigma_D)_{Heel} \cdot HWIDTH = 2.7\ klf$ *(resultant dead load of heel)*

$D_{Key} := (\sigma_D)_{Key} \cdot TK = 1.6\ klf$ *(resultant dead load of key)*

$D := D_{Heel} + D_{Key} = 4.3\ klf$ *(resultant dead load of heel including key per linear foot of wall)*

$(x_{D.heel})_{heel} := \frac{HWIDTH}{2} = 4.5\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_{D.key})_{heel} := HWIDTH - \left(\frac{TK}{2}\right) = 7.5\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_D)_{heel} := \frac{D_{Heel} \cdot (x_{D.heel})_{heel} + D_{Key} \cdot (x_{D.key})_{heel}}{D_{Heel} + D_{Key}} = 5.6\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation including the key)*

Hydrostatic Loads - Top of Heel

Note: hydrostatic loads applied in three directions, notated as ah = above heel, fh = face of heel and bh = behind heel

$(\sigma_{Hs})_{ah} := \gamma_{water} \cdot HTS = 0.624\ ksf$ *(vertical water pressure from hydrostatic loading)*

$(Hs)_{ah} := (\sigma_{Hs})_{ah} \cdot HWIDTH = 5.6\ klf$ *(vertical water loading from hydrostatic loading)*

$(x_{Hs})_{ah} := \frac{HWIDTH}{2} = 4.5\ ft$ *(moment arm for vertical hydrostatic loading)*

Hydrostatic Loads - Face of Heel

$(\sigma_{Hs})_{fh.top} := \gamma_{water} \cdot HTS = 0.624\ ksf$ *(min horizontal hydrostatic loading, top of foundation)*

$(\sigma_{Hs})_{fh.bot} := \gamma_{water} \cdot (HTS + THEEL) = 0.967\ ksf$ *(min horizontal hydrostatic loading, bot of key)*

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(Hs)_{fh} := \frac{THEEL \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{2} = 4.4\ klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}\right) = 3.95\ ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.756 \\ 0.883 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.809 \\ 0.959 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(Hs)_{bh} := \frac{HK \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{2} = \begin{bmatrix} 2.7 \\ 3.2 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}\right) = \begin{bmatrix} 2.8 \\ 2.8 \end{bmatrix} ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Face of Heel

$(\sigma_{EH})_{fh.top} := \gamma'_{soil} \cdot k_0 \cdot HSD = 0.052\ ksf$ *(min horizontal soil loading, top of foundation)*

$(\sigma_{EH})_{fh.bot} := \gamma'_{soil} \cdot k_0 \cdot (HSD + THEEL) = 0.22\ ksf$ *(min horizontal soil loading, top of foundation)*

Note: conservatively the lateral earth pressure does not include the undrained case where the lateral soil pressure would be zero.

$THEEL = 5.5\ ft$ *(depth of applied loading)*

$(EH)_{fh} := \frac{THEEL \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{2} = 0.7\ klf$ *(resultant of the soil loading to the front face of heel)*

$(x_{EH})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{3 \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}\right) = 4.318\ ft$ *(moment arm for the soil loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.2 \\ 1.01 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bh.bot} = \begin{bmatrix} 1.2 \\ 1.01 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3.5\ ft$ *(depth of key from the back side face)*

$(EH)_{bh} := \frac{HK \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{2} = \begin{bmatrix} 4.2 \\ 3.5 \end{bmatrix} klf$ *(resultant of the horizontal soil loading to the back face of heel)*

$(x_{EH})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{3 \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}\right) = \begin{bmatrix} 2.8 \\ 2.8 \end{bmatrix} ft$ *(moment arm for the soil loading to the back face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Vertical Earth Pressures - Top of Heel

$(\sigma_{EV})_{ah} := \gamma'_{soil} \cdot HSD = 0.097\ ksf$ *(vertical buoyant soil pressure on heel)*

$(EV)_{ah} := (\sigma_{EV})_{ah} \cdot HWIDTH = 0.88\ klf$ *(vertical buoyant soil loading on heel)*

$(x_{EV})_{ah} := \frac{HWIDTH}{2} = 4.5\ ft$ *(moment arm for vertical soil loading)*

Soil Pressure Loading - Base of Heel

$L_0 := BWIDTH - BIC = \begin{bmatrix} 1.35 \\ 3.2 \end{bmatrix} ft$ *(length of base with no soil pressure loading, measured from front face of key back toward toe)*

$L := HWIDTH - L_0 = \begin{bmatrix} 7.65 \\ 5.8 \end{bmatrix} ft$ *(length of base with soil pressure loading, measured from beginning of pressure back toward connection)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{L}{(\sigma_{SP})_{heel}}$ *(similar triangles relationship between the total soil pressure load and the length of the base in compression to the length of the heel in compression to the maximum soil pressure loading at the connection)*

$(\sigma_{SP})_{heel} := \overrightarrow{-L \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} 0.93 \\ 0.86 \end{bmatrix} ksf$ *(maximum soil pressure loading at the connection of the heel)*

$SP_{heel} := \overrightarrow{0.5 \cdot (\sigma_{SP})_{heel} \cdot L} = \begin{bmatrix} 3.57 \\ 2.49 \end{bmatrix} klf$ *(resultant soil pressure loading on the heel)*

$(x_{SP})_{heel} := \frac{1}{3} L = \begin{bmatrix} 2.5 \\ 1.9 \end{bmatrix} ft$ *(moment arm for the soil pressure loading, measured from the connection of the heel)*

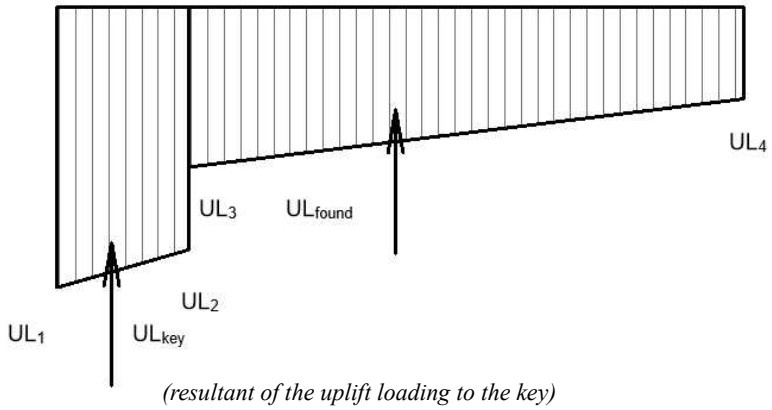
Uplifting Pressure

$UL_1 := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*



$UL_{key} := \frac{TK \cdot (UL_1 + UL_2)}{2} = \begin{bmatrix} 3.1 \\ 3.6 \end{bmatrix} klf$ *(resultant of the uplift loading to the key)*

$Heel\_Width := HWIDTH - TK = 6\ ft$ *(length of the heel; from the connection of the stem to the back face of the key)*

$(x_{UL})_{key} := Heel\_Width + \left(\frac{TK \cdot (2 \cdot UL_1 + UL_2)}{3 \cdot (UL_1 + UL_2)} \right) = \begin{bmatrix} 7.51 \\ 7.51 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

$m := \frac{(UL_4 - UL_3)}{BWIDTH - TK} = \begin{bmatrix} -0.0316 \\ -0.0416 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship between the uplift pressure from the foundation behind the key)*

$UL_{stem} := m \cdot (HWIDTH - TK) + UL_3 = \begin{bmatrix} 0.5 \\ 0.6 \end{bmatrix} ksf$ *(uplift pressure at the stem)*

$UL_{found} := \frac{Heel\_Width \cdot (UL_3 + UL_{stem})}{2} = \begin{bmatrix} 3.8 \\ 4.4 \end{bmatrix} klf$ *(resultant of the uplift loading to the foundation; less the key)*

$(x_{UL})_{found} := \left(\frac{Heel\_Width \cdot (2 \cdot UL_3 + UL_{stem})}{3 \cdot (UL_3 + UL_{stem})} \right) = \begin{bmatrix} 3.15 \\ 3.17 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

Load Combinations

Note: Forces that are oriented to the left and up are considered negative forces and moments that would rotate the heel counterclockwise are positive for the purpose of summing forces and moments.

Forces on Heel - Horizontal Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left((EH)_{fh} - (EH)_{bh} \right) \\ + \left((Hs)_{fh} - (Hs)_{bh} \right) \end{pmatrix} = \begin{bmatrix} -2.9 \\ -2.6 \end{bmatrix} klf$ *(Summation of the forces in the horizontal direction note positive forces represent heel in compression)*

$(\Sigma F_{heelc})_{horz} := \max(LC1) = -2.6\ klf$

$(\Sigma F_{heel})_{horz} := \max\left(\overrightarrow{|LC1|}\right) = 2.9\ klf$ *(maximum of the drained vs undrained cases)*

$P\_Check :=$ if $(\Sigma F_{heelc})_{horz} > 0$
"Heel is in compression, conservatively ignore axial loads in moment capcacity check"
else
"Heel in tension, factored into moment capcacity check"

$P\_Check =$ "Heel in tension, factored into moment capcacity check"

$(\Sigma F_{heel})_{Tension} :=$ if $(\Sigma F_{heel})_{horz} > 0$ $= 0\ kip$
$0\ kip$
else
$|(\Sigma F_{heel})_{horz}| \cdot b$

Forces on Heel - Vertical Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} D + (EV)_{ah} + (Hs)_{ah} \\ + \left(UL_{key} + UL_{found}\right) + \left(SP_{heel}\right) \end{pmatrix} = \begin{bmatrix} 33.9 \\ 33.9 \end{bmatrix} klf$ *(summation of the forces in the vertical direction)*

$(\Sigma F_{heel})_{vert} := \max\left(LC1\right) = 33.9\ klf$ *(maximum of the drained vs undrained cases)*

Resultant Shear at Base

$Vu_{heel} := (\Sigma F_{heel})_{vert} = 33.9\ klf$ *(factored shear at connection of floodwall heel)*

Resultant Axial Load in Base

$(P_u)_{heel} := (\Sigma F_{heel})_{horz} = 2.9\ klf$ *(factored axial load at floodwall heel)*

$(\Sigma F_{heel})_{Tension} = 0\ ft \cdot klf$ *(tension in heel; from check above, zero if heel in compression)*

Note: Axial loads with positive values put the heel of the floodwall in compression and negative values put the heel of the floodwall in tension.

Resultant Moment - on Heel at Stem Face

$LC1_{pos} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{D \cdot (x_D)_{heel}}\right) \\ + \left(\overrightarrow{(EV)_{ah} \cdot (x_{EV})_{ah}}\right) + \left(\overrightarrow{(Hs)_{ah} \cdot (x_{Hs})_{ah}}\right) \\ + \left(\overrightarrow{(EH)_{fh} \cdot (x_{EH})_{fh}}\right) + \left(\overrightarrow{(Hs)_{fh} \cdot (x_{Hs})_{fh}}\right) \end{pmatrix} = 117.9\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{neg} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{(Hs)_{bh} \cdot (x_{Hs})_{bh}}\right) \\ + \left(\overrightarrow{(EH)_{bh} \cdot (x_{EH})_{bh}}\right) \\ + \left(\overrightarrow{SP_{heel} \cdot (x_{SP})_{heel}}\right) \\ + \left(\overrightarrow{UL_{key} \cdot (x_{UL})_{key}}\right) \\ + \left(\overrightarrow{UL_{found} \cdot (x_{UL})_{found}}\right) \end{pmatrix} = \begin{bmatrix} 101.3 \\ 102.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$\Sigma LC := \max\left(LC1_{pos} - LC1_{neg}\right) = 16.61\ kip$

$Mu_{heel} := \max\left(LC1_{pos} - LC1_{neg}\right) \cdot b = 16.6\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

Note: since section is under tension and flexure, heel to be designed per section B-4 of EM 1110-2-2104.

Heel Reinforcement

$Mu_{heel} = 16.6\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

$(P_u)_{heel} = 2.9\ \frac{kip}{ft}$ *(maximum factored axial tension at base of floodwall stem on the heel)*

$Vu_{heel} = 33.9\ \frac{kip}{ft}$ *(maximum factored shear at base of floodwall stem on the heel)*

Top Bars - Main Steel

$(d_b)_{heel.top} :=$ Bar Size: #8 $= 1\ in$ *(top bar size in heel)*

$(d_b)_{heel.bot} :=$ Bar Size: #8 $= 1\ in$ *(bottom bar size in heel)*

$s_{heel.top} := 12\ in$ *(top bar spacing in heel)*

$s_{heel.bot} := 12\ in$ *(bottom bar spacing in heel)*

$c_{heel.top} := 3''\ \text{cover}$ *(cover for top reinforcement in heel)*

$c_{heel.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in heel)*

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

FLOOD LOAD CASES

Unusual Case

Top of Wall, ACE = 100 year event, Unusual Case

WSE = Top of Protection

Usual Case

ACE = 10 year event, Usual Case

WSE elevation below the top of the foundation

Note: The Unusual Flood Case with water to the top of the wall governs the design of this floodwall. Non-flood condition loads such as construction, seismic and wind are addressed in the stem design; however, it is apparent that the top of wall flood condition governs stability and the primary steel design so only the Unusual top of wall flood load is considered for stability and the base design.

The Usual Flood Case does not have water to the top of the foundation and is not included in these calculations.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$\gamma'_{soil} := \gamma_{soil} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$q_n := 2000\ psi$ *(bearing pressure, Reference DDR Table 9.2)*

Drained Soil Conditions

$\phi_{drained} := 28\ deg$ *(internal friction angle for drained soil condition)*

$C_{drained} := 0\ psf$ *(cohesion for drained soil condition)*

$k_0 := 1 - \sin\left(\phi_{drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

Undrained Soil Conditions

$\phi_{undrained} := 0\ deg$ *(internal friction angle for drained soil condition)*

$C_{undrained} := 1000\ psf$ *(cohesion for drained soil condition)*

$(k_0)_{undrained} := 1 - \sin\left(\phi_{undrained}\right) = 1$ *(at-rest soil pressure coefficient for the undrained condition)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(young's modulus of elasticity for steel)*

$(F_y)_{30} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$(F_y)_{60} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$\varepsilon_{ty} := \frac{(F_y)_{60}}{E_{steel}} = 0.0021$ *(yield strain of 60 ksi steel)*

Concrete Properties

$f'_c := 4500\ psi$ *(concrete compressive strength for all structures)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength for all structures)*

$q\lambda_c := 1.0$ *(concrete modification factor)*

$cover_3 := 3\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$cover_4 := 4\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$\gamma_{conc} := 150\ pcf$ *(concrete unit weight)*

$Ec := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$ *(young's modulus of elasticity for concrete)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

Load Factors

Serviceability Load Factors

Note: the unusual loading condition is used for the top of the floodwalls since they are designed to the 100 year event. the usual loading condition is defined as the 10 year event.

$(\gamma_p)_{Serve.u} := 2.2$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

$(\gamma_p)_{Serve.n} := 1.6$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

Strength Limit States

$\phi_b := 0.9$ *(bending load reduction factor - ACI 318-19 21.2.2, Table 21.2.2)*

$\phi_A := 0.9$

$\phi_V := 0.75$ *(shear load reduction factor - ACI 318-19 Table 21.2.1)*

CT WALL DATA

Input Data - Drained

$ELTS := 930.66\ ft$

$HTS := 8\ ft$

$TTS := 1.5\ ft$

$TBS := 1.5\ ft$

$THEEL := 5\ ft$

$TTOE := 2\ ft$

$TWIDTH := 4.5\ ft$

$BWIDTH := 10.5\ ft$

$HK := 3\ ft$

$TK := 2.5\ ft$

$Elev_{soil.d} := 924.20\ ft$ *(driving side soil elevation)*

$Elev_{soil.r} := 924.20\ ft$ *(resisting side soil elevation)*

$ELTF := ELTS - HTS = 922.7\ ft$ *(calculated top of foundation elevation)*

$ELTK := ELTF - THEEL + HK = 920.7\ ft$ *(calculated top of key, bottom of foundation elevation)*

$HSD := Elev_{soil.d} - ELTF = 1.5\ ft$ *(calculated depth of soil, driving side)*

$HSR := Elev_{soil.r} - ELTF = 1.5\ ft$ *(calculated depth of soil, resisting side)*

DRAINED CASE

CTWALL OUTPUT

Lateral Earth Loading

$\sigma_{EHd} := \begin{bmatrix} 0.12 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side, bottom of key; Drained, Undrained)*

$\sigma_{EHr} := \begin{bmatrix} 0.111 \\ 0.18 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side, bottom of foundation at toe; Drained, Undrained)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} := \begin{bmatrix} 0.871 \\ 0.697 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation; Drained, Undrained)*

$(\sigma_{EH})_{bh.bot} := \begin{bmatrix} 0.871 \\ 0.697 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key, Drained, Undrained)*

Impact Loading

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

Soil Pressure

$(\sigma_{SP})_{max} := -\begin{bmatrix} 0.922 \\ 0.923 \end{bmatrix} ksf$ *(max base soil loading from CT Wall Output)*

Uplift Pressure

$UL_1 := \begin{bmatrix} 0.699 \\ 0.811 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 0.666 \\ 0.766 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.430 \\ 0.511 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.292 \\ 0.320 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$(\sigma_{UL})_{min} := UL_4 = \begin{bmatrix} 0.292 \\ 0.32 \end{bmatrix} ksf$ *(minimum uplift pressure at the end of the toe)*

$(\sigma_{UL})_{max} := UL_3 = \begin{bmatrix} 0.43 \\ 0.511 \end{bmatrix} ksf$ *(maximum uplift pressure behind the key)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} := \begin{bmatrix} 0.666 \\ 0.766 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

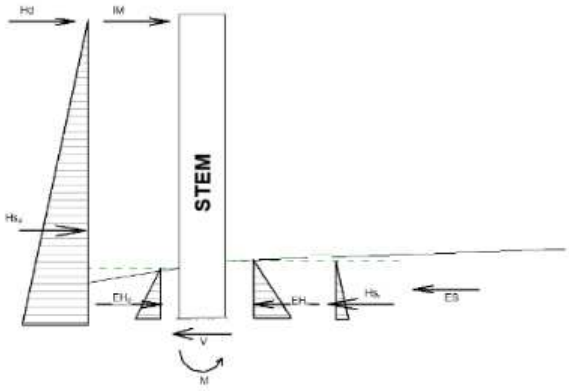
$(\sigma_{Hs})_{bh.bot} := \begin{bmatrix} 0.699 \\ 0.811 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

STEM DESIGN, RIVER SIDE

Loads to Stem

Note: largest loading from drained and undrained cases used to determine the controlling load case. In each loading condition, drained loads are listed first and undrained last.

This design for the riverside steel, along with the EnerCalc calculations, attached will be used for the landside steel design for simplicity. By inspection, the riverside reinforcement is sufficient for the landside reinforcement design.



Hydrostatic Loads

$\sigma_{Hsd} := \begin{bmatrix} \gamma_{water} \cdot HTS \\ \gamma_{water} \cdot HTS \end{bmatrix} = \begin{bmatrix} 499.2 \\ 499.2 \end{bmatrix} psf$ *(hydrostatic pressure loading to driving side)*

$Hs_d := \overrightarrow{0.5 \cdot \sigma_{Hsd} \cdot HTS} = \begin{bmatrix} 1.997 \\ 1.997 \end{bmatrix} klf$ *(hydrostatic loading to driving side)*

$(x_{Hs})_d := HTS \cdot \frac{1}{3} = 2.7\ ft$ *(moment arm for hydrostatic loading to the driving side from the base of the stem)*

Note: assume that hydrostatic loading from the resisting side of the T-wall provided from groundwater up to the ground surface. Assume that all additional water from the resisting side, landside, of the floodwall is conveyed away through interior drainage systems.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 96.1 \\ 96.1 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{0.5 \cdot \sigma_{Hsr} \cdot HSR} = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(hydrostatic loading to resisting side)*

$(x_{Hs})_r := HSR \cdot \frac{1}{3} = 0.51\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Lateral Earth Loading

$(\sigma_{EHd})_{stem} := \sigma_{EHd} \cdot \left(\frac{HSD}{HSD + THEEL} \right) = \begin{bmatrix} 0.028 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side of stem)*

$EH_d := \overrightarrow{0.5 \cdot (\sigma_{EHd})_{stem} \cdot HSD} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to driving side of stem)*

$(x_{EH})_d := HSD \cdot \frac{1}{3} = 0.5\ ft$ *(moment arm for lateral earth loading to the driving side from the base of the stem)*

$(\sigma_{EHr})_{stem} := \sigma_{EHr} \cdot \frac{HSR}{HSR + TTOE} = \begin{bmatrix} 0.048 \\ 0.078 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side of stem)*

$EH_r := \overrightarrow{0.5 \cdot (\sigma_{EHr})_{stem} \cdot HSR} = \begin{bmatrix} 0 \\ 0.1 \end{bmatrix} klf$ *(lateral earth loading to resisting side of stem)*

$(x_{EH})_r := HSR \cdot \frac{1}{3} = 0.5\ ft$ *(moment arm for lateral earth loading to the resisting side from the base of the stem)*

Impact Loading

Note: reference DDR for discussion of impact loading on floodwalls.

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

$(x_{IM})_d := HTS = 8\ ft$ *(moment arm of the impact load from the base of the stem)*

Operating Equipment

$p_{const} := 250\ psf$ *(construction surcharge loading)*

Note: assume that the surcharge loading is uniform and that the resultant is mid-height of the soil depth.

$d_{soil} := HSR = 1.5\ ft$ *(depth of soil cover on stem)*

$(x_Q)_d := \frac{HSR}{2} = 0.8\ ft$ *(resultant height above base of stem)*

$x_Q := d_{soil} - (x_Q)_d = 0.8\ ft$ *(depth from resultant to top of soil)*

$\sigma_H := p_{const} \cdot k_0 = 0.133\ ksf$ *(lateral linear pressure applied to wall)*

$Q := \sigma_H \cdot HSR = 0.204\ klf$ *(lateral surcharge load to structure, usual case)*

Wind

Note: for conservative analysis, wind loading only applied to the driving side as a positive pressure or applied to the resisting side as a negative pressure.

$(p_w)_p := 30.4\ psf$ *(primary wind pressure, reference DDR)*

$(p_w)_c := 15.8\ psf$ *(companion wind pressure, reference DDR)*

$G := 0.85\ \frac{1}{ft}$ *(gust factor, ASCE 7-16 Section 26.11.1)*

$C_f := 1.3$ *(force coefficient from ASCE 7-16, figure 29.3-1, s/h = 1 and B/s = '>45')*

$d := HTS - HSR = 6.5\ ft$ *(exposed surface of the stem for wind pressure)*

$A_s := 1\ ft \cdot d = 6.5\ ft^2$ *(exposed surface area of the wall per linear foot)*

$W_c := (p_w)_c \cdot G \cdot C_f \cdot A_s = 0.113\ klf$ *(wind loading, usual case for companion loading)*

$W_p := (p_w)_p \cdot G \cdot C_f \cdot A_s = 0.217\ klf$ *(wind loading, unusual case)*

$(x_W)_d := HTS - \frac{d}{2} = 4.8\ ft$ *(resultant height above base of stem)*

Earthquake Loading: Equivalent Lateral Force

$D_{wall} := (TTS \cdot HTS) \cdot \gamma_{conc} = 1.8\ \frac{1}{ft} \cdot kip$ *(dead load of the stem of the wall)*

$I_e := 1.5$ *(importance factor, ASCE 7-16 Table 1.5-2)*

$R := 2.5$ *(response modification factor, ASCE 7-16, Table 12.2-1, Item G.3)*

$S_{DS} := 0.101$ *(seismic spectral acceleration for short period)*

$Cs := \frac{S_{DS}}{\frac{R}{I_e}} = 0.1$ *(seismic response coefficient, ASCE 7-16 12.8-2)*

$V := Cs \cdot D_{wall} = 0.1\ klf$ *(seismic base shear, ASCE 7-16, EQ 12.8-1)*

$EQ := V = 0.1\ klf$

$(x_{EQ}) := HSR = 1.5\ ft$ *(resultant height above base of stem)*

Load Combinations

Note: Usual design cases not considered here as the Usual pool level does not reach the base of the stem.

Driving Side Forces

$LC1_d := (\gamma_p)_{Serve.n} \cdot \langle EH_d + Hs_d + IM \rangle = \begin{bmatrix} 3.4 \\ 3.4 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \langle EH_d + EQ \rangle = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \langle EH_d + Q \rangle = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix} klf$ *(load case 3 for construction)*

Resisting Side Forces

$LC1_r := (\gamma_p)_{Serve.n} \cdot \langle EH_r + Hs_r - W_c \rangle = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \langle EH_r \rangle = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \langle EH_r \rangle = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(load case 4 for construction)*

Resultant Shear at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 3.4 \\ 3.3 \end{bmatrix} klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.3 \\ 0.2 \end{bmatrix} klf$ *(equilibrium load case 3)*

$\Sigma F_{stem} := \text{stack}(LC1, LC2, LC3)$

Note: Maximum factored shear loading to the stem is the governing loading for the river side steel design. Minimum factored shear loading is the governing landside steel design.

$(Vu)_{stem} := \max(\Sigma F_{stem}) = 3.4\ klf$ *(resultant factored shear at base of floodwall stem, driving side)*

Resultant Moment - Driving Side

$LC1_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Hs_d \cdot (x_{Hs})_d \right) + IM \cdot (x_{IM})_d \right) = \begin{bmatrix} 9.8 \\ 9.8 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) \right) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Q \cdot \left((x_Q)_d \right) \right) \right) = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction)*

Resultant Moment - Resisting Side

$LC1_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) + \left(Hs_r \cdot (x_{Hs})_r \right) \right) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum flooding)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0.03 \\ 0.05 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0.03 \\ 0.05 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction or surcharge loading)*

Resultant Moment at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 9.7 \\ 9.7 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0 \\ 0 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 3)*

$\Sigma M_{stem} := \text{stack}(LC1, LC2, LC3)$ *(resultant factored moment at base of floodwall stem)*

$(Mu)_{stem} := \max(\Sigma M_{stem}) \cdot 1\ ft = 9.7\ kip \cdot ft$ *(resultant moment at base of floodwall stem, riverside steel design)*

Design Check Function

(system check for capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing arrays)

$$Check_v\left(X_U, X_N\right) := \left| \begin{array}{l} \text{for } i \in \mathbf{ORIGIN} .. \text{last}\left(X_U\right) \\ \quad \left| \begin{array}{l} \text{if } X_{U_i} > X_{N_i} \\ \quad \left| \begin{array}{l} ch_{i,1} \leftarrow \text{“NO GOOD”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \\ \text{else if } X_{N_i} = 0 \\ \quad \left| ch_{i,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left| \begin{array}{l} ch_{i,1} \leftarrow \text{“OK”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing scalar values)

$$Check\left(X_U, X_N\right) := \left| \begin{array}{l} \text{if } X_U > X_N \\ \quad \left| \begin{array}{l} ch_{1,1} \leftarrow \text{“NO GOOD”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ \text{else if } X_U = 0 \\ \quad \left| ch_{1,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left| \begin{array}{l} ch_{1,1} \leftarrow \text{“OK”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

$b := 12\ in$ *(strip width for analysis)*

Stem Reinforcement

Vertical Bars

$(d_b)_{stem.vert} :=$ Bar Size: #8 $= 1\ in$ *(vertical bar size in stem)*

$s_{stem.vert} := 12\ in$ *(vertical bar spacing in stem)*

$c_{stem.vert} :=$ 3″ cover *(cover for vertical reinforcement in stem)*

$$(A_s)_{stem.vert} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.vert}^{\ 2} \cdot b}{s_{stem.vert}} = 0.785\ in^2$$ *(area of steel vertical reinforcement in stem)*

$d_{stem.vert} := TTS - c_{stem.vert} - \left(0.5 \cdot (d_b)_{stem.vert}\right) = 14.5\ in$ *(depth to reinforcement vertical reinforcement in stem)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{stem} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$$a_{stem.vert} := \frac{(A_s)_{stem.vert} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}} = 0.85\ in$$

(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)

$$(\phi M_n)_{stem.vert} := \phi_b \cdot (A_s)_{stem.vert} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{a_{stem.vert}}{2}\right) = 49.7\ kip \cdot ft$$

(nominal flexural strength, EM1110-2-2104, B-49)

$$(Flex_{nom})_{Stem} := Check\left((Mu)_{stem}, (\phi M_n)_{stem.vert}\right) = [\text{“OK”} \quad 0.2]$$

(nominal flexural check, with Utilization ratio)

Minimum Required Steel for Flexure

Solve Constraints Given Values

$$As_{req} := 1.5\ in^2$$

$$(Mu)_{stem} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$$

$$As_{req.stem} := \mathbf{find}\left(\mathbf{As_{req}}\right) = 0.151\ in^2$$

$$(A_{s.min})_{stem.ten} := As_{req.stem} = 0.151\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.584\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.58\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTS \cdot b) = 0.324\ in^2$$

(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$

(minimum area of steel required for flexural capacity)

$$A_{s.min} = 0.584\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{stem.ten} \cdot \frac{4}{3} = 0.201\ in^2$$

(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)

$$(A_s)_{stem.req} := \begin{cases} as \leftarrow (A_{s.min})_{stem.ten} & \text{if } A_{s\_1.3} < (A_s)_{stem.vert} \\ as \leftarrow A_{s.min} & \text{else} \end{cases} = 0.151\ in^2$$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{stem.vert} = 0.8\ in^2$$

(area of steel provided in the vertical direction for the stem)

$$(Steel\_Check_{Vert})_{Stem} := Check\left((A_s)_{stem.req}, (A_s)_{stem.vert}\right) = [\text{“OK”} \quad 0.2]$$

(check stem reinforcement to required reinforcement)

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Vert.ts})_{Stem} := Check\left((A_{s.min})_{temp}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$ *(check stem reinforcement to temperature and shrinkage requirements)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{stem.vert}}{\left(b \cdot d_{stem.vert}\right)} = 0.0045$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{Stem} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{stem.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in stem)*

$s_{stem.lat} := 12\ in$ *(lateral bar spacing in stem)*

$(A_s)_{stem.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.lat}^{\ 2} \cdot 12\ in}{s_{stem.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in stem)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot \left(TTS \cdot b\right)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.3\ in^2$

$(A_s)_{stem.lat} = 0.4\ in^2$ *(area of steel provided in the lateral direction for the stem)*

$(Steel\_Check_{Lat})_{Stem} := Check\left(A_{s.req}, (A_s)_{stem.lat}\right) = [\text{"OK"} \quad 0.7]$ *(check stem reinforcement to required reinforcement)*

Riverside Reinforcement

Primary Reinforcement

$(d_b)_{stem.vert} = 1\ in$ *bars located at* $s_{stem.vert} = 12\ in$ *centers*

Lateral Reinforcement

$(d_b)_{stem.lat} = 0.75\ in$ *bars located at* $s_{stem.lat} = 12\ in$ *centers*

Deflection Check

Note: Reference provided justification file for loading conditions and attached EnerCalc calculations for the deflections in floodwall stem since stem thickness is less than H/8. From EnerCalc report, wall deflections limited to H/6838, which is less than expected movement capacity in waterstop and wall joints. 8 ft tall floodwalls to have stems with above detailed reinforcement.

Landside Reinforcement

For design simplicity, landside reinforcement to match both primary and lateral reinforcement.

STEM SHEAR CONNECTION TO FOUNDATION

Shear Friction

$f_y := (F_y)_{60} = 60000\ psi$ *(yield strength of reinforcing steel)*

$\mu := 1.0$

$(d_b)_{stem.vert.2} :=$ Bar Size: #6 $= 0.75\ in$ *(vertical bar size in stem)*

$s_{stem.vert2} := 12\ in$

$A_{vf} := \left(\frac{\pi}{4}\right) \cdot (d_b)_{stem.vert.2}{}^2 \cdot \left(\frac{b}{s_{stem.vert2}}\right) = 0.4\ in^2$

$V_n := \mu \cdot A_{vf} \cdot f_y = 26.5\ kip$ *(shear-friction strength, ACI 318-19, eq 22.9.4.2)*

Table 22.9.4.2—Coefficients of friction

Contact surface condition	Coefficient of friction μ[1]	
Concrete placed monolithically	1.4λ	(a)
Concrete placed against hardened concrete that is clean, free of laitance, and intentionally roughened to a full amplitude of approximately 1/4 in.	1.0λ	(b)
Concrete placed against hardened concrete that is clean, free of laitance, and not intentionally roughened	0.6λ	(c)
Concrete placed against as-rolled structural steel that is clean, free of paint, and with shear transferred across the contact surface by headed studs or by welded deformed bars or wires.	0.7λ	(d)

[1]λ = 1.0 for normalweight concrete. For lightweight concrete, λ is calculated as given in 19.2.4, but shall not exceed 0.85.

Table 22.9.4.4—Maximum V_n across the assumed shear plane

Condition	Maximum V_n		
Normalweight concrete placed monolithically or placed against hardened concrete intentionally roughened to a full amplitude of approximately 1/4 in.	Least of (a), (b), and (c)	$0.2f'_cA_c$	(a)
		$(480 + 0.08f'_c)A_c$	(b)
		$1600A_c$	(c)
Other cases	Lesser of (d) and (e)	$0.2f'_cA_c$	(d)
		$800A_c$	(e)

Maximum Shear Friction

$A_c := b \cdot TTS = 1.5\ ft^2$

$(V_n)_a := 0.2\ f'_c \cdot A_c = 194.4\ kip$ *(shear-friction maximum, equation a, Table 22.9.4.4)*

$(V_n)_b := \left(480\ psi + 0.08 \cdot f'_c\right) \cdot A_c = 181.4\ kip$ *(shear-friction maximum, equation b, Table 22.9.4.4)*

$(V_n)_c := \left(16000\ psi\right) A_c = 3456\ kip$ *(shear-friction maximum, equation c, Table 22.9.4.4)*

$(V_n)_{max} := \max\left((V_n)_a, (V_n)_b, (V_n)_c\right) = 3456\ kip$ *(shear-friction maximum, Table 22.9.4.4)*

Shear Strength

$\phi_V = 0.75$ *(reduction factor for shear capacity)*

$\phi_V V_n := \phi_V \cdot min\left((V_n)_{max}, V_n\right) = 19.9\ kip$ *(factored shear-friction strength)*

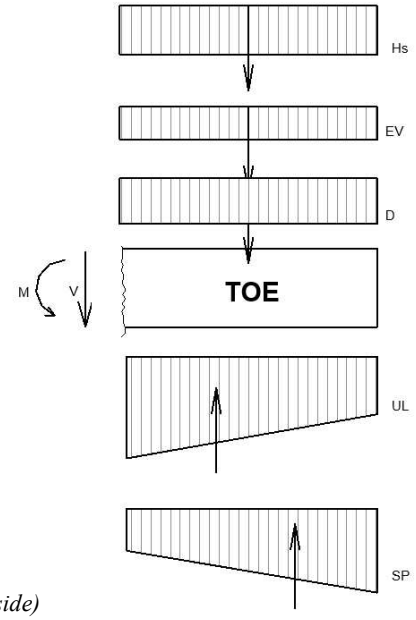
$V_{stem} := (Vu)_{stem} \cdot b = 3.4\ kip$ *(calculated shear required at base of stem)*

$V_{check} := Check\left(V_{stem}, \phi_V V_n\right) = [\text{"OK"} \quad 0.2]$ *(shear check, utilization ratio)*

Toe Check

Loads to Toe

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



Dead Load

$\sigma_D := \gamma_{conc} \cdot TTOE = 300\ psf$

$D := \sigma_D \cdot TWIDTH = 1.4\ klf$ *(resultant dead load of toe)*

$(x_D)_{toe} := \frac{TWIDTH}{2} = 2.3\ ft$ *(moment arm of the dead loading from the connection of the toe to the foundation)*

Hydrostatic Loads Above Toe

Note: Groundwater assumed to the soil surface. Potential additional seepage pressure conservatively ignored.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 96.1 \\ 96.1 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{TWIDTH \cdot \sigma_{Hsr}} = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} klf$ *(Resultant hydrostatic loading to resisting side)*

$(x_{Hs})_r := TWIDTH \cdot 0.5 = 2.25\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Vertical Earth Pressure

$\sigma_{EV} := \gamma'_{soil} \cdot HSR = 88.7\ psf$

$EV_r := \begin{bmatrix} \sigma_{EV} \cdot TWIDTH \\ \sigma_{EV} \cdot TWIDTH \end{bmatrix} = \begin{bmatrix} 0.399 \\ 0.399 \end{bmatrix} klf$ *(buoyant force of vertical soil loading)*

$(x_{EV})_r := \frac{TWIDTH}{2} = 2.3\ ft$

Soil Pressure

$(\sigma_{SP})_{max} = \begin{bmatrix} -0.922 \\ -0.923 \end{bmatrix} ksf$ *(max soil loading from CT Wall Output)*

$BWIDTH = 10.5\ ft$ *(total length of base of wall)*

$BIC_{percent} := \begin{bmatrix} 89.61 \\ 75.35 \end{bmatrix}\%$ *(percent of the base in compression)*

$BIC := BWIDTH \cdot BIC_{percent} = \begin{bmatrix} 9.4 \\ 7.9 \end{bmatrix} ft$ *(length of base in compression)*

$TWIDTH = 4.5\ ft$ *(length of toe of the foundation)*

note: using the length of the toe to determine the soil loading at the the connection of the toe to the stem and heel, use similar triangles to determine the loading at the connection of the toe.

$NTWIDTH := BIC - TWIDTH = \begin{bmatrix} 4.9 \\ 3.4 \end{bmatrix} ft$ *(length of the not-toe of the foundation in compression)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{NTWIDTH}{(\sigma_{SP})_1}$ *(relationship of similar triangles)*

$(\sigma_{SP})_1 := \overrightarrow{NTWIDTH \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} -0.48 \\ -0.4 \end{bmatrix} ksf$ *(soil pressure loading at the connection of the toe)*

$SP_{toe} := \frac{TWIDTH \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)}{2} = \begin{bmatrix} -3.2 \\ -3 \end{bmatrix} klf$ *(resultant soil loading to the toe of the foundation)*

$$(x_{SP})_{toe} := \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{SP})_{max}\right) + (\sigma_{SP})_1\right)}{3 \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)} = \begin{bmatrix} 2.5 \\ 2.5 \end{bmatrix} ft$$

(moment arm from the connection of the toe to the resultant of the soil pressure loading)

Uplift Pressures

$$(\sigma_{UL})_{min} = \begin{bmatrix} 0.292 \\ 0.32 \end{bmatrix} ksf$$

(minimum uplift pressure at the end of the toe)

$$(\sigma_{UL})_{max} = \begin{bmatrix} 0.43 \\ 0.511 \end{bmatrix} ksf$$

(maximum uplift pressure behind the key)

Note: Uplift pressure drops off linearly from the back of the key to the toe of the foundation

$BWIDTH = 10.5\ ft$ *(foundation width)*

$TK = 2.5\ ft$ *(key width)*

$L := BWIDTH - TK = 8\ ft$ *(length of linear uplift pressure)*

$(\sigma_{UL})_{max} - (\sigma_{UL})_{min} = m(L)$ *(linear relationship)*

$$m := \frac{(\sigma_{UL})_{max} - (\sigma_{UL})_{min}}{L} = \begin{bmatrix} 0.0173 \\ 0.0239 \end{bmatrix} \frac{ksf}{ft}$$

(linear relationship)

$$(\sigma_{UL})_{max.toe} := \overrightarrow{(m \cdot TWIDTH) + (\sigma_{UL})_{min}} = \begin{bmatrix} 0.37 \\ 0.427 \end{bmatrix} ksf$$

(uplift pressure at the connection of the toe to the foundation)

$$UL_{toe} := \frac{-TWIDTH \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)}{2} = \begin{bmatrix} -1.5 \\ -1.7 \end{bmatrix} klf$$

(uplift pressure resultant for the toe of the foundation)

$$(x_{UL})_{toe} := TWIDTH - \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{UL})_{max.toe}\right) + (\sigma_{UL})_{min}\right)}{3 \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)} = \begin{bmatrix} 2.2 \\ 2.1 \end{bmatrix} ft$$

(distance from the connection of the toe to the resultant of the uplift pressure)

Load Combinations

Resisting Side Forces - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \left(D + EV_r + Hs_r + SP_{toe} + UL_{toe}\right) = \begin{bmatrix} -3.9 \\ -4 \end{bmatrix} klf$$

(load case 1 for infrequent flooding)

$$\Sigma F_{toe} := \max\left(\overrightarrow{|LC1|}\right) = 4\ klf$$

(maximum of the drained vs undrained cases)

Factored Shear on Toe at Face of Stem

$$(V_u)_{toe} := \Sigma F_{toe} = 4\ klf$$

(maximum factored shear in toe)

Resultant Moment - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(D \cdot (x_D)_{toe}\right) + \left(\overrightarrow{Hs_r \cdot (x_{Hs})_r}\right) \\ + \left(\overrightarrow{EV_r \cdot (x_{EV})_r}\right) + \left(\overrightarrow{SP_{toe} \cdot (x_{SP})_{toe}}\right) \\ + \left(\overrightarrow{UL_{toe} \cdot (x_{UL})_{toe}}\right) \end{pmatrix} = \begin{bmatrix} -9.9 \\ -10 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case 1 for infrequent flooding)

Maximum Factored Moment in Toe at Face of Stem

$Mu_{toe} := \max(LC1) \cdot 1\ ft = -9.9\ kip \cdot ft$ *(resultant moment at base of floodwall stem per foot of wall)*

$Mu_{toe} := -Mu_{toe}$

Toe Reinforcement

Bottom Bars - Main Steel

$(d_b)_{toe.bot} := \boxed{\text{Bar Size: \#8}} = 1\ in$ *(bottom bar size in toe)*

$s_{toe.bot} := 12\ in$ *(bottom bar spacing in toe)*

$c_{toe.bot} := \boxed{4''\ \text{cover}}$ *(cover for bottom reinforcement in toe)*

$(A_s)_{toe.bot} := \dfrac{0.25 \cdot \pi \cdot (d_b)_{toe.bot}^{\ 2} \cdot b}{s_{toe.bot}} = 0.785\ in^2$ *(area of steel for bottom reinforcement in toe)*

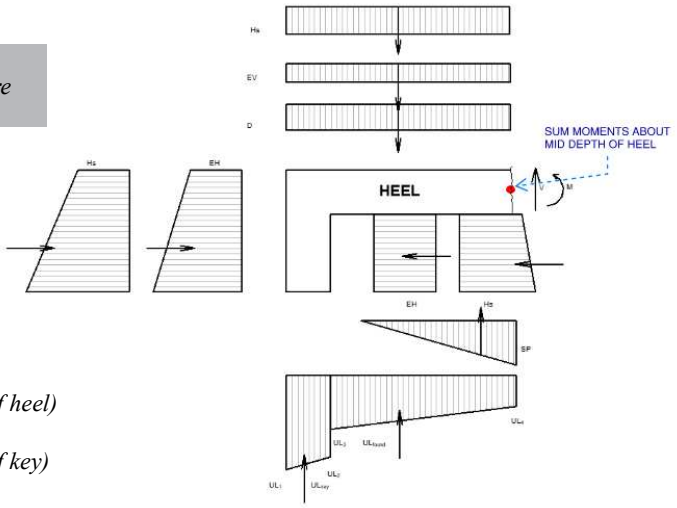
Toe - Top Lateral Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

HEEL DESIGN

Loads to Heel

Note: largest loading from drained and undrained cases used to create conservative design for loading. In each loading condition, drained loads are listed first and undrained last



$HWIDTH := BWIDTH - TTS - TWIDTH = 4.5\ ft$

(Length of heel, includes key)

Dead Load

$(\sigma_D)_{Heel} := \gamma_{conc} \cdot (TTOE) = 300\ psf$

$(\sigma_D)_{Key} := \gamma_{conc} \cdot (HK) = 450\ psf$

$D_{Heel} := (\sigma_D)_{Heel} \cdot HWIDTH = 1.4\ klf$ *(resultant dead load of heel)*

$D_{Key} := (\sigma_D)_{Key} \cdot TK = 1.1\ klf$ *(resultant dead load of key)*

$D := D_{Heel} + D_{Key} = 2.5\ klf$ *(resultant dead load of heel including key per linear foot of wall)*

$(x_{D.heel})_{heel} := \frac{HWIDTH}{2} = 2.3\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_{D.key})_{heel} := HWIDTH - \left(\frac{TK}{2}\right) = 3.3\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_D)_{heel} := \frac{D_{Heel} \cdot (x_{D.heel})_{heel} + D_{Key} \cdot (x_{D.key})_{heel}}{D_{Heel} + D_{Key}} = 2.7\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation including the key)*

Hydrostatic Loads - Top of Heel

Note: hydrostatic loads applied in three directions, notated as ah = above heel, fh = face of heel and bh = behind heel

$(\sigma_{Hs})_{ah} := \gamma_{water} \cdot HTS = 0.499\ ksf$ *(vertical water pressure from hydrostatic loading)*

$(Hs)_{ah} := (\sigma_{Hs})_{ah} \cdot HWIDTH = 2.2\ klf$ *(vertical water loading from hydrostatic loading)*

$(x_{Hs})_{ah} := \frac{HWIDTH}{2} = 2.25\ ft$ *(moment arm for vertical hydrostatic loading)*

Hydrostatic Loads - Face of Heel

$(\sigma_{Hs})_{fh.top} := \gamma_{water} \cdot HTS = 0.499\ ksf$ *(min horizontal hydrostatic loading, top of foundation)*

$(\sigma_{Hs})_{fh.bot} := \gamma_{water} \cdot (HTS + THEEL) = 0.811\ ksf$ *(min horizontal hydrostatic loading, bot of key)*

$THEEL = 5\ ft$ *(depth of applied loading)*

$(Hs)_{fh} := \frac{THEEL \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{2} = 3.3\ klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}\right) = 3.7\ ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.666 \\ 0.766 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.699 \\ 0.811 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(Hs)_{bh} := \frac{HK \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{2} = \begin{bmatrix} 2 \\ 2.4 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}\right) = \begin{bmatrix} 2.5 \\ 2.5 \end{bmatrix} ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Face of Heel

$(\sigma_{EH})_{fh.top} := \gamma'_{soil} \cdot k_0 \cdot HSD = 0.047\ ksf$ *(min horizontal soil loading, top of foundation)*

$(\sigma_{EH})_{fh.bot} := \gamma'_{soil} \cdot k_0 \cdot (HSD + THEEL) = 0.2\ ksf$ *(min horizontal soil loading, top of foundation)*

Note: conservatively the lateral earth pressure does not include the undrained case where the lateral soil pressure would be zero.

$THEEL = 5\ ft$ *(depth of applied loading)*

$(EH)_{fh} := \frac{THEEL \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{2} = 0.6\ klf$ *(resultant of the soil loading to the front face of heel)*

$(x_{EH})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{3 \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}\right) = 4.016\ ft$ *(moment arm for the soil loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} = \begin{bmatrix} 0.87 \\ 0.7 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bh.bot} = \begin{bmatrix} 0.87 \\ 0.7 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(EH)_{bh} := \frac{HK \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{2} = \begin{bmatrix} 2.6 \\ 2.1 \end{bmatrix} klf$ *(resultant of the horizontal soil loading to the back face of heel)*

$(x_{EH})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{3 \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}\right) = \begin{bmatrix} 2.5 \\ 2.5 \end{bmatrix} ft$ *(moment arm for the soil loading to the back face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Vertical Earth Pressures - Top of Heel

$(\sigma_{EV})_{ah} := \gamma'_{soil} \cdot HSD = 0.089\ ksf$ *(vertical buoyant soil pressure on heel)*

$(EV)_{ah} := (\sigma_{EV})_{ah} \cdot HWIDTH = 0.4\ klf$ *(vertical buoyant soil loading on heel)*

$(x_{EV})_{ah} := \frac{HWIDTH}{2} = 2.25\ ft$ *(moment arm for vertical soil loading)*

Soil Pressure Loading - Base of Heel

$L_0 := BWIDTH - BIC = \begin{bmatrix} 1.09 \\ 2.59 \end{bmatrix} ft$ *(length of base with no soil pressure loading, measured from front face of key back toward toe)*

$L := HWIDTH - L_0 = \begin{bmatrix} 3.41 \\ 1.91 \end{bmatrix} ft$ *(length of base with soil pressure loading, measured from beginning of pressure back toward connection)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{L}{(\sigma_{SP})_{heel}}$ *(similar triangles relationship between the total soil pressure load and the length of the base in compression to the length of the heel in compression to the maximum soil pressure loading at the connection)*

$(\sigma_{SP})_{heel} := \overrightarrow{-L \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} 0.33 \\ 0.22 \end{bmatrix} ksf$ *(maximum soil pressure loading at the connection of the heel)*

$SP_{heel} := \overrightarrow{0.5 \cdot (\sigma_{SP})_{heel} \cdot L} = \begin{bmatrix} 0.57 \\ 0.21 \end{bmatrix} klf$ *(resultant soil pressure loading on the heel)*

$(x_{SP})_{heel} := \frac{1}{3} L = \begin{bmatrix} 1.1 \\ 0.6 \end{bmatrix} ft$ *(moment arm for the soil pressure loading, measured from the connection of the heel)*

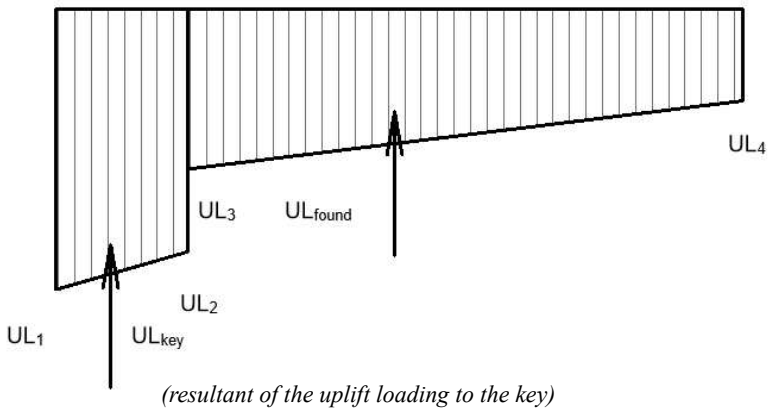
Uplifting Pressure

$UL_1 := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*



$UL_{key} := \frac{TK \cdot \langle UL_1 + UL_2 \rangle}{2} = \begin{bmatrix} 2.6 \\ 3 \end{bmatrix} klf$ *(resultant of the uplift loading to the key)*

$Heel\_Width := HWIDTH - TK = 2\ ft$ *(length of the heel; from the connection of the stem to the back face of the key)*

$(x_{UL})_{key} := Heel\_Width + \left(\frac{TK \cdot \langle 2 \cdot UL_1 + UL_2 \rangle}{3 \cdot \langle UL_1 + UL_2 \rangle} \right) = \begin{bmatrix} 3.26 \\ 3.26 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

$m := \frac{\langle UL_4 - UL_3 \rangle}{BWIDTH - TK} = \begin{bmatrix} -0.0395 \\ -0.052 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship between the uplift pressure from the foundation behind the key)*

$UL_{stem} := m \cdot (HWIDTH - TK) + UL_3 = \begin{bmatrix} 0.6 \\ 0.8 \end{bmatrix} ksf$ *(uplift pressure at the stem)*

$UL_{found} := \frac{Heel\_Width \cdot \langle UL_3 + UL_{stem} \rangle}{2} = \begin{bmatrix} 1.4 \\ 1.6 \end{bmatrix} klf$ *(resultant of the uplift loading to the foundation; less the key)*

$(x_{UL})_{found} := \left(\frac{Heel\_Width \cdot \langle 2 \cdot UL_3 + UL_{stem} \rangle}{3 \cdot \langle UL_3 + UL_{stem} \rangle} \right) = \begin{bmatrix} 1.02 \\ 1.02 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

Load Combinations

Note: Forces that are oriented to the left and up are considered negative forces and moments that would rotate the heel counterclockwise are positive for the purpose of summing forces and moments.

Forces on Heel - Horizontal Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \langle (EH)_{fh} - (EH)_{bh} \rangle \\ + \langle (Hs)_{fh} - (Hs)_{bh} \rangle \end{pmatrix} = \begin{bmatrix} -1.2 \\ -0.9 \end{bmatrix} klf$ *(Summation of the forces in the horizontal direction note positive forces represent heel in compression)*

$(\Sigma F_{heelc})_{horz} := \max(LC1) = -0.9\ klf$

$(\Sigma F_{heel})_{horz} := \max\left(\overrightarrow{|LC1|}\right) = 1.2\ klf$ *(maximum of the drained vs undrained cases)*

$P\_Check :=$ if $(\Sigma F_{heelc})_{horz} > 0$
"Heel is in compression, conservatively ignore axial loads in moment capcacity check"
else
"Heel in tension, factored into moment capcacity check"

$P\_Check =$ "Heel in tension, factored into moment capcacity check"

$(\Sigma F_{heel})_{Tension} :=$ if $(\Sigma F_{heel})_{horz} > 0$
$0\ kip$
else
$|(\Sigma F_{heel})_{horz}| \cdot b$
$= 0\ kip$

Forces on Heel - Vertical Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} D + (EV)_{ah} + (Hs)_{ah} \\ + \left(UL_{key} + UL_{found}\right) + \left(SP_{heel}\right) \end{pmatrix} = \begin{bmatrix} 15.4 \\ 15.9 \end{bmatrix} klf$ *(summation of the forces in the vertical direction)*

$(\Sigma F_{heel})_{vert} := \max\left(LC1\right) = 15.9\ klf$ *(maximum of the drained vs undrained cases)*

Resultant Shear at Base

$Vu_{heel} := (\Sigma F_{heel})_{vert} = 15.9\ klf$ *(factored shear at connection of floodwall heel)*

Resultant Axial Load in Base

$(P_u)_{heel} := (\Sigma F_{heel})_{horz} = 1.2\ klf$ *(factored axial load at floodwall heel)*

$(\Sigma F_{heel})_{Tension} = 0\ ft \cdot klf$ *(tension in heel; from check above, zero if heel in compression)*

Note: Axial loads with positive values put the heel of the floodwall in compression and negative values put the heel of the floodwall in tension.

Resultant Moment - on Heel at Stem Face

$LC1_{pos} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{D \cdot (x_D)_{heel}}\right) \\ + \left(\overrightarrow{(EV)_{ah} \cdot (x_{EV})_{ah}}\right) + \left(\overrightarrow{(Hs)_{ah} \cdot (x_{Hs})_{ah}}\right) \\ + \left(\overrightarrow{(EH)_{fh} \cdot (x_{EH})_{fh}}\right) + \left(\overrightarrow{(Hs)_{fh} \cdot (x_{Hs})_{fh}}\right) \end{pmatrix} = 43.6\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{neg} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{(Hs)_{bh} \cdot (x_{Hs})_{bh}}\right) \\ + \left(\overrightarrow{(EH)_{bh} \cdot (x_{EH})_{bh}}\right) \\ + \left(\overrightarrow{SP_{heel} \cdot (x_{SP})_{heel}}\right) \\ + \left(\overrightarrow{UL_{key} \cdot (x_{UL})_{key}}\right) \\ + \left(\overrightarrow{UL_{found} \cdot (x_{UL})_{found}}\right) \end{pmatrix} = \begin{bmatrix} 35.4 \\ 36.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$\Sigma LC := \max\left(LC1_{pos} - LC1_{neg}\right) = 8.23\ kip$

$Mu_{heel} := \max\left(LC1_{pos} - LC1_{neg}\right) \cdot b = 8.2\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

Note: since section is under tension and flexure, heel to be designed per section B-4 of EM 1110-2-2104.

Heel Reinforcement

$Mu_{heel} = 8.2\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

$(P_u)_{heel} = 1.2\ \frac{kip}{ft}$ *(maximum factored axial tension at base of floodwall stem on the heel)*

$Vu_{heel} = 15.9\ \frac{kip}{ft}$ *(maximum factored shear at base of floodwall stem on the heel)*

$AxialCheck := Check\left((\Sigma F_{heel})_{horz} \cdot b, \phi Pn\right) = [\text{“OK”} \quad 0.01]$ *(tensile)*

Flexural Check

$\phi M_{n.Heel} := \phi_b \cdot \left(0.85 \cdot f'_c \cdot a_{heel.top} \cdot b \cdot \left(d_{heel.top} - \dfrac{a_{heel.top}}{2}\right) - (P_u)_{heel} \cdot \left(d_{heel.top} - \dfrac{TTOE}{2}\right) \cdot b\right) = 42.1\ kip \cdot ft$

(moment capacity for beam in flexure and axial tension, EM 2104, Eq D-1)

$(M_{Flex\_Axial})_{Heel} := Check\left(Mu_{heel}, \phi M_{n.Heel}\right) = [\text{“OK”} \quad 0.2]$

Minimum Required Steel for Flexure

Given

Constraints

Values

$As_{req} := 1.5\ in^2$

$Mu_{heel} = \phi_b \cdot \left(\left(As_{req} \cdot (F_y)_{60} \cdot \left(d_{heel.top} - \dfrac{As_{req} \cdot (F_y)_{60} + (P_u)_{heel} \cdot b}{0.85 \cdot f'_c \cdot d_{heel.top}}\right)\right) - \left((P_u)_{heel} \cdot \left(d_{heel.top} - \dfrac{TTOE}{2}\right) \cdot b\right)\right)$

Solver

$As_{req.stem} := \text{find}\left(\mathbf{As_{req}}\right) = 0.098\ in^2$

(minimum steel required for flexural strength)

$(A_{s.min})_{heel.top} := As_{req.stem} = 0.1\ in^2$

Minimum Required Steel per ACI

$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.825\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.82\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

temperature and shrinkage reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.432\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b, (A_{s.min})_{temp}\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.825\ in^2$

$A_{s\_1.3} := (A_{s.min})_{heel.top} \cdot \frac{4}{3} = 0.1\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{heel.req} :=$ if $A_{s\_1.3} < (A_s)_{heel.top}$ $as \leftarrow (A_{s.min})_{heel.top}$ else $as \leftarrow A_{s.min}$ $= 0.098\ in^2$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{heel.top} = 0.8\ in^2$ *(area of steel provided in the horizontal direction for the heel)*

$(Steel\_Check_{Top})_{heel} := Check\left((A_s)_{heel.req}, (A_s)_{heel.top}\right) = [\text{"OK"} \quad 0.12]$ *(check stem reinforcement to required reinforcement)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{actual} := \frac{(A_s)_{heel.top}}{\left(b \cdot d_{heel.top}\right)} = 0.0032$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{top})_{heel} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.4]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Note: Current version of EM 1110-2-2104 provides this limit as a guidance. This is ok

Lateral Bars

$(d_b)_{heel.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in heel)*

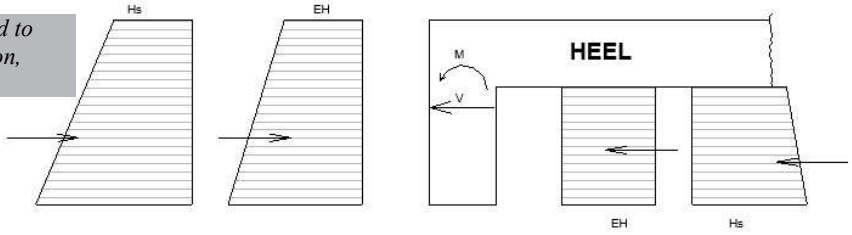
KEY DESIGN

Loads to Key

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



$HK = 3\ ft$ *(depth of key, from bottom of foundation down)*

$THEEL = 5\ ft$ *(depth of key, from top of foundation down)*

Hydrostatic Loads - Front of Key

Note: hydrostatic loads applied in two directions, notated as fk = front of key and bk = back of key

$(\sigma_{Hs})_{fk1} := \gamma_{water} \cdot (HTS + TTOE) = 0.624\ ksf$ *(horizontal water loading, top of key)*

$(\sigma_{Hs})_{fk2} := \gamma_{water} \cdot (HTS + THEEL) = 0.811\ ksf$ *(horizontal water loading, bottom of key)*

$(Hs)_{fk} := \frac{HK \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})}{2} = 2.2\ klf$ *(hydrostatic loading to the front of key)*

$(x_{Hs})_{fk} := \frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{fk2}) + (\sigma_{Hs})_{fk1})}{3 \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})} = 1.57\ ft$ *(moment arm for hydrostatic loading, measured down from key connection to foundation)*

Hydrostatic Loads - Back of key

$(\sigma_{Hs})_{bk.top} := (\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.666 \\ 0.766 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bk.bot} := (\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.699 \\ 0.811 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(Hs)_{bk} := \frac{HK \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{2} = \begin{bmatrix} 2 \\ 2.4 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of the key)*

$(x_{Hs})_{bk} := \left(\frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{3 \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})} \right) = \begin{bmatrix} 1.5 \\ 1.5 \end{bmatrix} ft$ *(moment arm of the hydrostatic loading to the front face of the key, measured down from the connection to foundation)*

Lateral Earth Pressures - Face of Key

$(\sigma_{EH})_{fk.top} := \gamma'_{soil} \cdot k_0 \cdot (HTS + TTOE) = 0.306\ ksf$ *(min horizontal lateral earth loading, top of foundation)*

$(\sigma_{EH})_{fk.bot} := \gamma'_{soil} \cdot k_0 \cdot (HTS + THEEL) = 0.397\ ksf$ *(min horizontal lateral earth loading, bottom of foundation)*

$THEEL = 5\ ft$ *(depth of applied loading)*

$(EH)_{fk} := \frac{HK \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{2} = 1.1\ klf$ *(resultant of the lateral earth loading to the front face of key)*

$(x_{EH})_{fk} := \frac{HK \cdot (2 \cdot (\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{3 \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})} = 1.565\ ft$ *(moment arm of the lateral earth loading to to the front face of the key, measured from the the connection of the key to the foundation)*

Lateral Earth Pressures - Back of Key

$(\sigma_{EH})_{bk.top} := (\sigma_{EH})_{bh.top} = \begin{bmatrix} 0.871 \\ 0.697 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bk.bot} := (\sigma_{EH})_{bh.bot} = \begin{bmatrix} 0.871 \\ 0.697 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(EH)_{bk} := \frac{HK \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{2} = \begin{bmatrix} 2.6 \\ 2.1 \end{bmatrix} klf$ *(resultant of the lateral earth loading to the back face of key)*

$(x_{EH})_{bk} := \frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{3 \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)} = \begin{bmatrix} 1.5 \\ 1.5 \end{bmatrix} ft$ *(moment arm for the lateral earth loading to the back face of the key, measured from the connection of the key to the foundation)*

Resultant Moment - on Toe

$LC1_{fk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{fk} \cdot (x_{EH})_{fk}}\right) + \left(\overrightarrow{(Hs)_{fk} \cdot (x_{Hs})_{fk}}\right)\right) = 8\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{bk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{bk} \cdot (x_{EH})_{bk}}\right) + \left(\overrightarrow{(Hs)_{bk} \cdot (x_{Hs})_{bk}}\right)\right) = \begin{bmatrix} 11.2 \\ 10.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$LC1_{key} := LC1_{bk} - LC1_{fk} = \begin{bmatrix} 3.2 \\ 2.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$

$Mu_{key} := \max\left(LC1_{bk} - LC1_{fk}\right) \cdot 1\ ft = 3.2\ kip \cdot ft$ *(factored maximum moment at connection of floodwall key to the heel)*

Key Reinforcement

Back Bars - Main Steel

$(d_b)_{key.main} :=$ Bar Size: #8 $= 1\ in$ *(main bar size in key)*

$s_{key.main} := 12\ in$ *(main bar spacing in key)*

$c_{key.main} :=$ 4″ cover *(cover for main reinforcement in key)*

$(A_s)_{key.main} := \frac{0.25 \cdot \pi \cdot (d_b)_{key.main}^{\ 2} \cdot 12\ in}{s_{key.main}} = 0.785\ in^2$ *(area of steel for top reinforcement in key)*

$d_{key.main} := TTOE - c_{key.main} - 0.5 \cdot (d_b)_{key.main} = 19.5\ in$ *(depth to main reinforcement in key)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{key.main} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot \left(f'_c - 4000\ psi\right)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.8$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{key.main} := \frac{(A_s)_{key.main} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{key.main}} = 0.6\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1)*

$(\phi M_n)_{key.main} := \phi_b \cdot (A_s)_{key.main} \cdot (F_y)_{60} \cdot \left(d_{key.main} - \frac{a_{key.main}}{2}\right) = 67.8\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

U.S.ARMY CORPS OF ENGINEERS - KANSAS CITY DISTRICT

T-Wall Load Cases and Strength Design

Upper Turkey Creek

Merriam, KS

ASSUMPTIONS

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

FLOOD LOAD CASES

Unusual Case

Top of Wall, ACE = 100 year event, Unusual Case

WSE = Top of Protection

Usual Case

ACE = 10 year event, Usual Case

WSE elevation below the top of the foundation

Note: The Unusual Flood Case with water to the top of the wall governs the design of this floodwall. Non-flood condition loads such as construction, seismic and wind are addressed in the stem design; however, it is apparent that the top of wall flood condition governs stability and the primary steel design so only the Unusual top of wall flood load is considered for stability and the base design.

The Usual Flood Case does not have water to the top of the foundation and is not included in these calculations.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$(\sigma_{UL})_{max} := UL_3 = \begin{bmatrix} 0.316 \\ 0.374 \end{bmatrix} ksf$ *(maximum uplift pressure behind the key)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} := \begin{bmatrix} 0.537 \\ 0.611 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

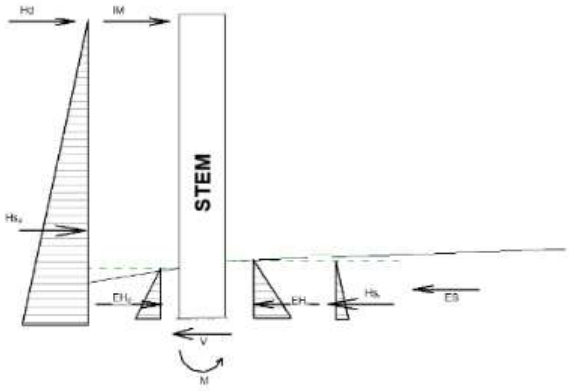
$(\sigma_{Hs})_{bh.bot} := \begin{bmatrix} 0.554 \\ 0.635 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

STEM DESIGN, RIVER SIDE

Loads to Stem

Note: largest loading from drained and undrained cases used to determine the controlling load case. In each loading condition, drained loads are listed first and undrained last.

This design for the riverside steel, along with the EnerCalc calculations, attached will be used for the landside steel design for simplicity. By inspection, the riverside reinforcement is sufficient for the landside reinforcement design.



Hydrostatic Loads

$\sigma_{Hsd} := \begin{bmatrix} \gamma_{water} \cdot HTS \\ \gamma_{water} \cdot HTS \end{bmatrix} = \begin{bmatrix} 374.4 \\ 374.4 \end{bmatrix} psf$ *(hydrostatic pressure loading to driving side)*

$Hs_d := \overrightarrow{0.5 \cdot \sigma_{Hsd} \cdot HTS} = \begin{bmatrix} 1.123 \\ 1.123 \end{bmatrix} klf$ *(hydrostatic loading to driving side)*

$(x_{Hs})_d := HTS \cdot \frac{1}{3} = 2\ ft$ *(moment arm for hydrostatic loading to the driving side from the base of the stem)*

Note: assume that hydrostatic loading from the resisting side of the T-wall provided from groundwater up to the ground surface. Assume that all additional water from the resisting side, landside, of the floodwall is conveyed away through interior drainage systems.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 93.6 \\ 93.6 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{0.5 \cdot \sigma_{Hsr} \cdot HSR} = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(hydrostatic loading to resisting side)*

$(x_{Hs})_r := HSR \cdot \frac{1}{3} = 0.5\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Lateral Earth Loading

$(\sigma_{EHd})_{stem} := \sigma_{EHd} \cdot \left(\frac{HSD}{HSD + THEEL} \right) = \begin{bmatrix} 0.049 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side of stem)*

$EH_d := \overrightarrow{0.5 \cdot (\sigma_{EHd})_{stem} \cdot HSD} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$ *(lateral earth loading to driving side of stem)*

$(x_{EH})_d := HSD \cdot \frac{1}{3} = 0.5\ ft$ *(moment arm for lateral earth loading to the driving side from the base of the stem)*

$(\sigma_{EHr})_{stem} := \sigma_{EHr} \cdot \frac{HSR}{HSR + TTOE} = \begin{bmatrix} 0.041 \\ 0.067 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side of stem)*

$EH_r := \overrightarrow{0.5 \cdot (\sigma_{EHr})_{stem} \cdot HSR} = \begin{bmatrix} 0 \\ 0.1 \end{bmatrix} klf$ *(lateral earth loading to resisting side of stem)*

$(x_{EH})_r := HSR \cdot \frac{1}{3} = 0.5\ ft$ *(moment arm for lateral earth loading to the resisting side from the base of the stem)*

Impact Loading

Note: reference DDR for discussion of impact loading on floodwalls.

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

$(x_{IM})_d := HTS = 6\ ft$ *(moment arm of the impact load from the base of the stem)*

Operating Equipment

$p_{const} := 250\ psf$ *(construction surcharge loading)*

Note: assume that the surcharge loading is uniform and that the resultant is mid-height of the soil depth.

$d_{soil} := HSR = 1.5\ ft$ *(depth of soil cover on stem)*

$(x_Q)_d := \frac{HSR}{2} = 0.8\ ft$ *(resultant height above base of stem)*

$x_Q := d_{soil} - (x_Q)_d = 0.8\ ft$ *(depth from resultant to top of soil)*

$\sigma_H := p_{const} \cdot k_0 = 0.133\ ksf$ *(lateral linear pressure applied to wall)*

$Q := \sigma_H \cdot HSR = 0.199\ klf$ *(lateral surcharge load to structure, usual case)*

Wind

Note: for conservative analysis, wind loading only applied to the driving side as a positive pressure or applied to the resisting side as a negative pressure.

$(p_w)_p := 30.4\ psf$ *(primary wind pressure, reference DDR)*

$(p_w)_c := 15.8\ psf$ *(companion wind pressure, reference DDR)*

$G := 0.85\ \frac{1}{ft}$ *(gust factor, ASCE 7-16 Section 26.11.1)*

$C_f := 1.3$ *(force coefficient from ASCE 7-16, figure 29.3-1, s/h = 1 and B/s = '>45')*

$d := HTS - HSR = 4.5\ ft$ *(exposed surface of the stem for wind pressure)*

$A_s := 1\ ft \cdot d = 4.5\ ft^2$ *(exposed surface area of the wall per linear foot)*

$W_c := (p_w)_c \cdot G \cdot C_f \cdot A_s = 0.079\ klf$ *(wind loading, usual case for companion loading)*

$W_p := (p_w)_p \cdot G \cdot C_f \cdot A_s = 0.151\ klf$ *(wind loading, unusual case)*

$(x_W)_d := HTS - \frac{d}{2} = 3.8\ ft$ *(resultant height above base of stem)*

Earthquake Loading: Equivalent Lateral Force

$D_{wall} := (TTS \cdot HTS) \cdot \gamma_{conc} = 1.4\ \frac{1}{ft} \cdot kip$ *(dead load of the stem of the wall)*

$I_e := 1.5$ *(importance factor, ASCE 7-16 Table 1.5-2)*

$R := 2.5$ *(response modification factor, ASCE 7-16, Table 12.2-1, Item G.3)*

$S_{DS} := 0.101$ *(seismic spectral acceleration for short period)*

$Cs := \frac{S_{DS}}{\frac{R}{I_e}} = 0.1$ *(seismic response coefficient, ASCE 7-16 12.8-2)*

$V := Cs \cdot D_{wall} = 0.1\ klf$ *(seismic base shear, ASCE 7-16, EQ 12.8-1)*

$EQ := V = 0.1\ klf$

$(x_{EQ}) := HSR = 1.5\ ft$ *(resultant height above base of stem)*

Load Combinations

Note: Usual design cases not considered here as the Usual pool level does not reach the base of the stem.

Driving Side Forces

$LC1_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Hs_d + IM) = \begin{bmatrix} 2 \\ 2 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot (EH_d + EQ) = \begin{bmatrix} 0.2 \\ 0.1 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Q) = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix} klf$ *(load case 3 for construction)*

Resisting Side Forces

$LC1_r := (\gamma_p)_{Serve.n} \cdot (EH_r + Hs_r - W_c) = \begin{bmatrix} 0 \\ 0.1 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0 \\ 0.1 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0 \\ 0.1 \end{bmatrix} klf$ *(load case 4 for construction)*

Resultant Shear at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 2 \\ 1.9 \end{bmatrix} klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.3 \\ 0.2 \end{bmatrix} klf$ *(equilibrium load case 3)*

$\Sigma F_{stem} := \text{stack}(LC1, LC2, LC3)$

Note: Maximum factored shear loading to the stem is the governing loading for the river side steel design. Minimum factored shear loading is the governing landside steel design.

$(Vu)_{stem} := \max(\Sigma F_{stem}) = 2\ klf$ *(resultant factored shear at base of floodwall stem, driving side)*

Resultant Moment - Driving Side

$LC1_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Hs_d \cdot (x_{Hs})_d \right) + IM \cdot (x_{IM})_d \right) = \begin{bmatrix} 4.6 \\ 4.6 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(EQ \cdot (x_{EQ}) \right) \right) = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d \right) + \left(Q \cdot \left((x_Q)_d \right) \right) \right) = \begin{bmatrix} 0.3 \\ 0.2 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction)*

Resultant Moment - Resisting Side

$LC1_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) + \left(Hs_r \cdot (x_{Hs})_r \right) \right) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum flooding)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r \right) \right) = \begin{bmatrix} 0 \\ 0 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction or surcharge loading)*

Resultant Moment at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 4.5 \\ 4.5 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 3)*

$\Sigma M_{stem} := \text{stack}(LC1, LC2, LC3)$ *(resultant factored moment at base of floodwall stem)*

$(Mu)_{stem} := \max(\Sigma M_{stem}) \cdot 1\ ft = 4.5\ kip \cdot ft$ *(resultant moment at base of floodwall stem, riverside steel design)*

Design Check Function

(system check for capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing arrays)

$$Check_v(X_U, X_N) := \left\| \begin{array}{l} \text{for } i \in \mathbf{ORIGIN} .. \text{last}(X_U) \\ \quad \left\| \begin{array}{l} \text{if } X_{U_i} > X_{N_i} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“NO GOOD”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \\ \text{else if } X_{N_i} = 0 \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“N/A”} \end{array} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“OK”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing scalar values)

$$Check(X_U, X_N) := \left\| \begin{array}{l} \text{if } X_U > X_N \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“NO GOOD”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ \text{else if } X_U = 0 \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“N/A”} \end{array} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“OK”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

$b := 12\ in$ *(strip width for analysis)*

Stem Reinforcement

Vertical Bars

$(d_b)_{stem.vert} :=$ Bar Size: #8 $= 1\ in$ *(vertical bar size in stem)*

$s_{stem.vert} := 12\ in$ *(vertical bar spacing in stem)*

$c_{stem.vert} :=$ 3″ cover *(cover for vertical reinforcement in stem)*

$$(A_s)_{stem.vert} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.vert}^{\ 2} \cdot b}{s_{stem.vert}} = 0.785\ in^2$$ *(area of steel vertical reinforcement in stem)*

$d_{stem.vert} := TTS - c_{stem.vert} - \left(0.5 \cdot (d_b)_{stem.vert}\right) = 14.5\ in$ *(depth to reinforcement vertical reinforcement in stem)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{stem} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$$

(beta value from ACI 318-19, Table 22.2.2.4.3)

$$a_{stem.vert} := \frac{(A_s)_{stem.vert} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}} = 0.85\ in$$

(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)

$$(\phi M_n)_{stem.vert} := \phi_b \cdot (A_s)_{stem.vert} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{a_{stem.vert}}{2}\right) = 49.7\ kip \cdot ft$$

(nominal flexural strength, EM1110-2-2104, B-49)

$$(Flex_{nom})_{Stem} := Check\left((Mu)_{stem}, (\phi M_n)_{stem.vert}\right) = [\text{"OK"} \quad 0.09]$$

(nominal flexural check, with Utilization ratio)

Minimum Required Steel for Flexure

Solve Constraints Given Values

$$As_{req} := 1.5\ in^2$$

$$(Mu)_{stem} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$$

$$As_{req.stem} := \mathbf{find}\left(\mathbf{As_{req}}\right) = 0.069\ in^2$$

$$(A_{s.min})_{stem.ten} := As_{req.stem} = 0.069\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.584\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.58\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTS \cdot b) = 0.324\ in^2$$

(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$

(minimum area of steel required for flexural capacity)

$$A_{s.min} = 0.584\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{stem.ten} \cdot \frac{4}{3} = 0.092\ in^2$$

(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)

$$(A_s)_{stem.req} := \begin{cases} as \leftarrow (A_{s.min})_{stem.ten} & \text{if } A_{s\_1.3} < (A_s)_{stem.vert} \\ as \leftarrow A_{s.min} & \text{else} \end{cases} = 0.069\ in^2$$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{stem.vert} = 0.8\ in^2$$

(area of steel provided in the vertical direction for the stem)

$$(Steel\_Check_{Vert})_{Stem} := Check\left((A_s)_{stem.req}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.1]$$

(check stem reinforcement to required reinforcement)

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Vert.ts})_{Stem} := Check\left((A_{s.min})_{temp}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$ *(check stem reinforcement to temperature and shrinkage requirements)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{stem.vert}}{\left(b \cdot d_{stem.vert}\right)} = 0.0045$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{Stem} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{stem.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in stem)*

$s_{stem.lat} := 12\ in$ *(lateral bar spacing in stem)*

$(A_s)_{stem.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.lat}^{\ 2} \cdot 12\ in}{s_{stem.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in stem)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot \left(TTS \cdot b\right)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.3\ in^2$

$(A_s)_{stem.lat} = 0.4\ in^2$ *(area of steel provided in the lateral direction for the stem)*

$(Steel\_Check_{Lat})_{Stem} := Check\left(A_{s.req}, (A_s)_{stem.lat}\right) = [\text{"OK"} \quad 0.7]$ *(check stem reinforcement to required reinforcement)*

Riverside Reinforcement

Primary Reinforcement

$(d_b)_{stem.vert} = 1\ in$ *bars located at* $s_{stem.vert} = 12\ in$ *centers*

Lateral Reinforcement

$(d_b)_{stem.lat} = 0.75\ in$ *bars located at* $s_{stem.lat} = 12\ in$ *centers*

Deflection Check

Note: Reference provided justification file for loading conditions and attached EnerCalc calculations for the deflections in floodwall stem since stem thickness is less than H/8. From EnerCalc report, wall deflections limited to H/6838, which is less than expected movement capacity in waterstop and wall joints. 6 ft tall floodwalls to have stems with above detailed reinforcement.

Landside Reinforcement

For design simplicity, landside reinforcement to match both primary and lateral reinforcement.

STEM SHEAR CONNECTION TO FOUNDATION

Shear Friction

$f_y := (F_y)_{60} = 60000\ psi$ *(yield strength of reinforcing steel)*

$\mu := 1.0$

$(d_b)_{stem.vert.2} :=$ Bar Size: #6 $= 0.75\ in$ *(vertical bar size in stem)*

$s_{stem.vert2} := 12\ in$

$A_{vf} := \left(\frac{\pi}{4}\right) \cdot (d_b)_{stem.vert.2}{}^2 \cdot \left(\frac{b}{s_{stem.vert2}}\right) = 0.4\ in^2$

$V_n := \mu \cdot A_{vf} \cdot f_y = 26.5\ kip$ *(shear-friction strength, ACI 318-19, eq 22.9.4.2)*

Table 22.9.4.2—Coefficients of friction

Contact surface condition	Coefficient of friction μ[1]	
Concrete placed monolithically	1.4λ	(a)
Concrete placed against hardened concrete that is clean, free of laitance, and intentionally roughened to a full amplitude of approximately 1/4 in.	1.0λ	(b)
Concrete placed against hardened concrete that is clean, free of laitance, and not intentionally roughened	0.6λ	(c)
Concrete placed against as-rolled structural steel that is clean, free of paint, and with shear transferred across the contact surface by headed studs or by welded deformed bars or wires.	0.7λ	(d)

[1]λ = 1.0 for normalweight concrete. For lightweight concrete, λ is calculated as given in 19.2.4, but shall not exceed 0.85.

Table 22.9.4.4—Maximum V_n across the assumed shear plane

Condition	Maximum V_n		
Normalweight concrete placed monolithically or placed against hardened concrete intentionally roughened to a full amplitude of approximately 1/4 in.	Least of (a), (b), and (c)	$0.2f'_cA_c$	(a)
		$(480 + 0.08f'_c)A_c$	(b)
		$1600A_c$	(c)
Other cases	Lesser of (d) and (e)	$0.2f'_cA_c$	(d)
		$800A_c$	(e)

Maximum Shear Friction

$A_c := b \cdot TTS = 1.5\ ft^2$

$(V_n)_a := 0.2\ f'_c \cdot A_c = 194.4\ kip$ *(shear-friction maximum, equation a, Table 22.9.4.4)*

$(V_n)_b := \left(480\ psi + 0.08 \cdot f'_c\right) \cdot A_c = 181.4\ kip$ *(shear-friction maximum, equation b, Table 22.9.4.4)*

$(V_n)_c := \left(16000\ psi\right) A_c = 3456\ kip$ *(shear-friction maximum, equation c, Table 22.9.4.4)*

$(V_n)_{max} := \max\left((V_n)_a, (V_n)_b, (V_n)_c\right) = 3456\ kip$ *(shear-friction maximum, Table 22.9.4.4)*

Shear Strength

$\phi_V = 0.75$ *(reduction factor for shear capacity)*

$\phi_V V_n := \phi_V \cdot min\left((V_n)_{max}, V_n\right) = 19.9\ kip$ *(factored shear-friction strength)*

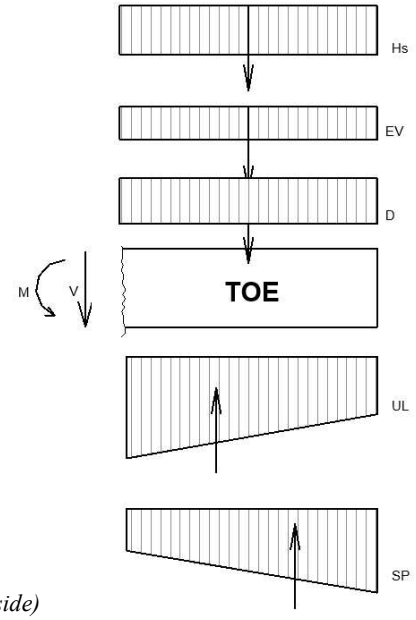
$V_{stem} := (Vu)_{stem} \cdot b = 2\ kip$ *(calculated shear required at base of stem)*

$V_{check} := Check\left(V_{stem}, \phi_V V_n\right) = [\text{“OK”} \quad 0.1]$ *(shear check, utilization ratio)*

Toe Check

Loads to Toe

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



Dead Load

$\sigma_D := \gamma_{conc} \cdot TTOE = 225\ psf$

$D := \sigma_D \cdot TWIDTH = 0.9\ klf$ *(resultant dead load of toe)*

$(x_D)_{toe} := \frac{TWIDTH}{2} = 2\ ft$ *(moment arm of the dead loading from the connection of the toe to the foundation)*

Hydrostatic Loads Above Toe

Note: Groundwater assumed to the soil surface. Potential additional seepage pressure conservatively ignored.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 93.6 \\ 93.6 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{TWIDTH \cdot \sigma_{Hsr}} = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} klf$ *(Resultant hydrostatic loading to resisting side)*

$(x_{Hs})_r := TWIDTH \cdot 0.5 = 2\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Vertical Earth Pressure

$\sigma_{EV} := \gamma'_{soil} \cdot HSR = 86.4\ psf$

$EV_r := \begin{bmatrix} \sigma_{EV} \cdot TWIDTH \\ \sigma_{EV} \cdot TWIDTH \end{bmatrix} = \begin{bmatrix} 0.346 \\ 0.346 \end{bmatrix} klf$ *(buoyant force of vertical soil loading)*

$(x_{EV})_r := \frac{TWIDTH}{2} = 2\ ft$

Soil Pressure

$(\sigma_{SP})_{max} = \begin{bmatrix} -0.852 \\ -0.822 \end{bmatrix} ksf$ *(max soil loading from CT Wall Output)*

$BWIDTH = 9\ ft$ *(total length of base of wall)*

$BIC_{percent} := \begin{bmatrix} 89.61 \\ 75.35 \end{bmatrix}\%$ *(percent of the base in compression)*

$BIC := BWIDTH \cdot BIC_{percent} = \begin{bmatrix} 8.1 \\ 6.8 \end{bmatrix} ft$ *(length of base in compression)*

$TWIDTH = 4\ ft$ *(length of toe of the foundation)*

note: using the length of the toe to determine the soil loading at the the connection of the toe to the stem and heel, use similar triangles to determine the loading at the connection of the toe.

$NTWIDTH := BIC - TWIDTH = \begin{bmatrix} 4.1 \\ 2.8 \end{bmatrix} ft$ *(length of the not-toe of the foundation in compression)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{NTWIDTH}{(\sigma_{SP})_1}$ *(relationship of similar triangles)*

$(\sigma_{SP})_1 := \overrightarrow{NTWIDTH \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} -0.43 \\ -0.34 \end{bmatrix} ksf$ *(soil pressure loading at the connection of the toe)*

$SP_{toe} := \frac{TWIDTH \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)}{2} = \begin{bmatrix} -2.6 \\ -2.3 \end{bmatrix} klf$ *(resultant soil loading to the toe of the foundation)*

$$(x_{SP})_{toe} := \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{SP})_{max}\right) + (\sigma_{SP})_1\right)}{3 \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)} = \begin{bmatrix} 2.2 \\ 2.3 \end{bmatrix} ft$$

(moment arm from the connection of the toe to the resultant of the soil pressure loading)

Uplift Pressures

$$(\sigma_{UL})_{min} = \begin{bmatrix} 0.23 \\ 0.25 \end{bmatrix} ksf$$

(minimum uplift pressure at the end of the toe)

$$(\sigma_{UL})_{max} = \begin{bmatrix} 0.316 \\ 0.374 \end{bmatrix} ksf$$

(maximum uplift pressure behind the key)

Note: Uplift pressure drops off linearly from the back of the key to the toe of the foundation

$BWIDTH = 9\ ft$ *(foundation width)*

$TK = 1.5\ ft$ *(key width)*

$L := BWIDTH - TK = 7.5\ ft$ *(length of linear uplift pressure)*

$(\sigma_{UL})_{max} - (\sigma_{UL})_{min} = m(L)$ *(linear relationship)*

$$m := \frac{(\sigma_{UL})_{max} - (\sigma_{UL})_{min}}{L} = \begin{bmatrix} 0.0115 \\ 0.0165 \end{bmatrix} \frac{ksf}{ft}$$

(linear relationship)

$$(\sigma_{UL})_{max.toe} := \overrightarrow{(m \cdot TWIDTH) + (\sigma_{UL})_{min}} = \begin{bmatrix} 0.276 \\ 0.316 \end{bmatrix} ksf$$

(uplift pressure at the connection of the toe to the foundation)

$$UL_{toe} := \frac{-TWIDTH \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)}{2} = \begin{bmatrix} -1 \\ -1.1 \end{bmatrix} klf$$

(uplift pressure resultant for the toe of the foundation)

$$(x_{UL})_{toe} := TWIDTH - \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{UL})_{max.toe}\right) + (\sigma_{UL})_{min}\right)}{3 \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)} = \begin{bmatrix} 1.9 \\ 1.9 \end{bmatrix} ft$$

(distance from the connection of the toe to the resultant of the uplift pressure)

Load Combinations

Resisting Side Forces - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \left(D + EV_r + Hs_r + SP_{toe} + UL_{toe}\right) = \begin{bmatrix} -3.1 \\ -2.9 \end{bmatrix} klf$$

(load case 1 for infrequent flooding)

$$\Sigma F_{toe} := \max\left(\overrightarrow{|LC1|}\right) = 3.1\ klf$$

(maximum of the drained vs undrained cases)

Factored Shear on Toe at Face of Stem

$$(V_u)_{toe} := \Sigma F_{toe} = 3.1\ klf$$

(maximum factored shear in toe)

Resultant Moment - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(D \cdot (x_D)_{toe}\right) + \left(\overrightarrow{Hs_r \cdot (x_{Hs})_r}\right) \\ + \left(\overrightarrow{EV_r \cdot (x_{EV})_r}\right) + \left(\overrightarrow{SP_{toe} \cdot (x_{SP})_{toe}}\right) \\ + \left(\overrightarrow{UL_{toe} \cdot (x_{UL})_{toe}}\right) \end{pmatrix} = \begin{bmatrix} -7.1 \\ -6.8 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case 1 for infrequent flooding)

Maximum Factored Moment in Toe at Face of Stem

$Mu_{toe} := \max(LC1) \cdot 1\ ft = -6.8\ kip \cdot ft$ *(resultant moment at base of floodwall stem per foot of wall)*

$Mu_{toe} := -Mu_{toe}$

Toe Reinforcement

Bottom Bars - Main Steel

$(d_b)_{toe.bot} := \boxed{\text{Bar Size: \#8}} = 1\ in$ *(bottom bar size in toe)*

$s_{toe.bot} := 12\ in$ *(bottom bar spacing in toe)*

$c_{toe.bot} := \boxed{4''\ \text{cover}}$ *(cover for bottom reinforcement in toe)*

$(A_s)_{toe.bot} := \dfrac{0.25 \cdot \pi \cdot (d_b)_{toe.bot}^{\ 2} \cdot b}{s_{toe.bot}} = 0.785\ in^2$ *(area of steel for bottom reinforcement in toe)*

$d_{toe.bot} := TTOE - c_{toe.bot} - \left(0.5 \cdot (d_b)_{toe.bot}\right) = 13.5\ in$ *(depth to reinforcement bottom reinforcement in toe)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{toe.bot} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\dfrac{0.05 \cdot \langle f'_c - 4000\ psi \rangle}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{toe.bot} := \dfrac{(A_s)_{toe.bot} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{toe.bot}} = 0.9\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)*

$(\phi M_n)_{toe.bot} := \phi_b \cdot (A_s)_{toe.bot} \cdot (F_y)_{60} \cdot \left(d_{toe.bot} - \dfrac{a_{toe.bot}}{2}\right) = 46.1\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{toe} := Check\left(Mu_{toe}, (\phi M_n)_{toe.bot}\right) = [\text{“OK”} \quad 0.15]$ *(nominal flexural check)*

Minimum Required Steel for Flexure

Solve Constraints Values

$As_{req} := 1.5\ in^2$

$Mu_{toe} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \dfrac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$

$(As_{req})_{toe} := \mathbf{find}\left(As_{req}\right) = 0.1\ in^2$ *(minimum required reinforcement for flexural strength)*

Minimum Required Steel per ACI

$(A_{s.min})_a := \dfrac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.543\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \dfrac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.5\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.543\ in^2$

$A_{s\_1.3} := (As_{req})_{toe} \cdot \frac{4}{3} = 0.1\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{toe.req} := \text{if } A_{s\_1.3} < (A_s)_{toe.bot} \ \| \ as \leftarrow (As_{req})_{toe} \ \text{else} \ \| \ as \leftarrow A_{s.min} = 0.104\ in^2$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{toe.bot} = 0.8\ in^2$ *(area of steel provided in the horizontal direction for the toe)*

$(Steel\_Check_{bot})_{toe} := Check\left((A_s)_{toe.req}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.1]$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$

$(Steel\_Check_{bot.ts})_{toe} := Check\left((A_{s.min})_{temp}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.4]$

(check stem reinforcement to required t&s reinforcement)

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{toe.bot}}{\left(b \cdot d_{toe.bot}\right)} = 0.0048$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{toe} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{toe.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in toe)*

$s_{toe.lat} := 12\ in$ *(lateral bar spacing in toe)*

$c_{toe.lat} :=$ 4″ cover *(cover for lateral reinforcement in toe)*

$(A_s)_{toe.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{toe.lat}^{\ 2} \cdot 12\ in}{s_{toe.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in toe)*

$d_{toe.lat} := TTS - c_{toe.lat} - (d_b)_{toe.bot} - 0.5 \cdot (d_b)_{toe.lat} = 12.625\ in$ *(depth to reinforcement lateral reinforcement in toe)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot (TTOE \cdot b)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.32\ in^2$

$(A_s)_{toe.lat} = 0.442\ in^2$ *(area of steel provided in the lateral direction for the toe, both faces)*

$(Steel\_Check_{Lat})_{toe} := Check\left(A_{s.req}, (A_s)_{toe.lat}\right) = [\text{"OK"} \quad 0.73]$ *(check toe reinforcement to required reinforcement)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{actual} := \frac{(A_s)_{toe.lat}}{\left(b \cdot d_{toe.bot}\right)} = 0.0027$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Lat})_{toe} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.4]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

SHEAR CHECK

$N_u := 0\ kip$ *(compressive axial force in toe of foundation, conservatively ignored for analysis)*

$A_g := TTOE \cdot b = 216\ in^2$ *(gross area of concrete section)*

$V_c := \left(\left(2 \cdot \sqrt{f'c}\right) \cdot psi + \frac{N_u}{6 \cdot A_g}\right) \cdot b \cdot d_{toe.bot} = 21.7\ kip$ *(shear strength in concrete, EM 1110-2-2104, Eq 5-1)*

$\phi_V V_n := \phi_V \cdot V_c = 16.3\ kip$ *(nominal shear strength in concrete, EM 1110-2-2104, Eq 5-1)*

$V_{toe} := \left|(V_u)_{toe} \cdot b\right| = 3.1\ kip$

$V_{toe.check} := Check\left(V_{toe}, \phi_V V_n\right) = [\text{“OK”} \quad 0.2]$

Toe - Bottom Reinforcement

$(d_b)_{toe.bot} = 1\ in$ *bars located at* $s_{toe.bot} = 12\ in$ *centers*

Toe - Lateral Reinforcement

$(d_b)_{toe.lat} = 0.75\ in$ *bars located at* $s_{toe.lat} = 12\ in$ *centers*

Toe - Top Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

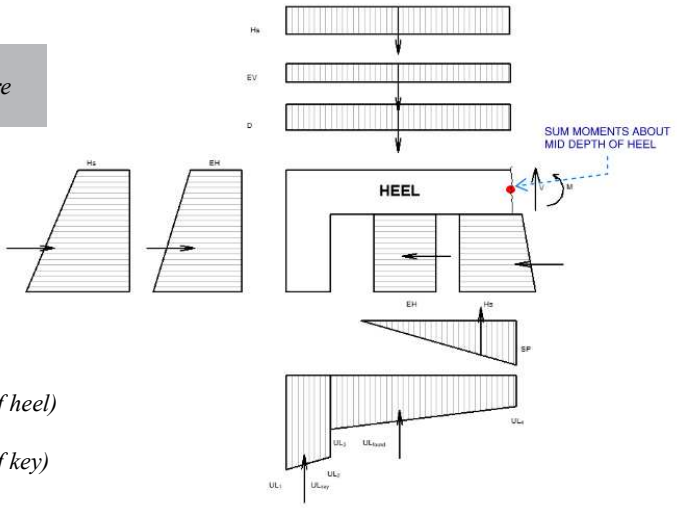
Toe - Top Lateral Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

HEEL DESIGN

Loads to Heel

Note: largest loading from drained and undrained cases used to create conservative design for loading. In each loading condition, drained loads are listed first and undrained last



$HWIDTH := BWIDTH - TTS - TWIDTH = 3.5\ ft$

(Length of heel, includes key)

Dead Load

$(\sigma_D)_{Heel} := \gamma_{conc} \cdot (TTOE) = 225\ psf$

$(\sigma_D)_{Key} := \gamma_{conc} \cdot (HK) = 450\ psf$

$D_{Heel} := (\sigma_D)_{Heel} \cdot HWIDTH = 0.8\ klf$ *(resultant dead load of heel)*

$D_{Key} := (\sigma_D)_{Key} \cdot TK = 0.7\ klf$ *(resultant dead load of key)*

$D := D_{Heel} + D_{Key} = 1.5\ klf$ *(resultant dead load of heel including key per linear foot of wall)*

$(x_{D.heel})_{heel} := \frac{HWIDTH}{2} = 1.8\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_{D.key})_{heel} := HWIDTH - \left(\frac{TK}{2}\right) = 2.8\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_D)_{heel} := \frac{D_{Heel} \cdot (x_{D.heel})_{heel} + D_{Key} \cdot (x_{D.key})_{heel}}{D_{Heel} + D_{Key}} = 2.2\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation including the key)*

Hydrostatic Loads - Top of Heel

Note: hydrostatic loads applied in three directions, notated as ah = above heel, fh = face of heel and bh = behind heel

$(\sigma_{Hs})_{ah} := \gamma_{water} \cdot HTS = 0.374\ ksf$ *(vertical water pressure from hydrostatic loading)*

$(Hs)_{ah} := (\sigma_{Hs})_{ah} \cdot HWIDTH = 1.3\ klf$ *(vertical water loading from hydrostatic loading)*

$(x_{Hs})_{ah} := \frac{HWIDTH}{2} = 1.75\ ft$ *(moment arm for vertical hydrostatic loading)*

Hydrostatic Loads - Face of Heel

$(\sigma_{Hs})_{fh.top} := \gamma_{water} \cdot HTS = 0.374\ ksf$ *(min horizontal hydrostatic loading, top of foundation)*

$(\sigma_{Hs})_{fh.bot} := \gamma_{water} \cdot (HTS + THEEL) = 0.655\ ksf$ *(min horizontal hydrostatic loading, bot of key)*

$THEEL = 4.5\ ft$ *(depth of applied loading)*

$(Hs)_{fh} := \frac{THEEL \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{2} = 2.3\ klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}\right) = 3.2\ ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.537 \\ 0.611 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.554 \\ 0.635 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(Hs)_{bh} := \frac{HK \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{2} = \begin{bmatrix} 1.6 \\ 1.9 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}\right) = \begin{bmatrix} 2.3 \\ 2.3 \end{bmatrix} ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Face of Heel

$(\sigma_{EH})_{fh.top} := \gamma'_{soil} \cdot k_0 \cdot HSD = 0.046\ ksf$ *(min horizontal soil loading, top of foundation)*

$(\sigma_{EH})_{fh.bot} := \gamma'_{soil} \cdot k_0 \cdot (HSD + THEEL) = 0.183\ ksf$ *(min horizontal soil loading, top of foundation)*

Note: conservatively the lateral earth pressure does not include the undrained case where the lateral soil pressure would be zero.

$THEEL = 4.5\ ft$ *(depth of applied loading)*

$(EH)_{fh} := \frac{THEEL \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{2} = 0.5\ klf$ *(resultant of the soil loading to the front face of heel)*

$(x_{EH})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{3 \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}\right) = 3.45\ ft$ *(moment arm for the soil loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} = \begin{bmatrix} 0.65 \\ 0.43 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bh.bot} = \begin{bmatrix} 0.65 \\ 0.43 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(EH)_{bh} := \frac{HK \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{2} = \begin{bmatrix} 1.9 \\ 1.3 \end{bmatrix} klf$ *(resultant of the horizontal soil loading to the back face of heel)*

$(x_{EH})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{3 \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}\right) = \begin{bmatrix} 2.3 \\ 2.3 \end{bmatrix} ft$ *(moment arm for the soil loading to the back face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Vertical Earth Pressures - Top of Heel

$(\sigma_{EV})_{ah} := \gamma'_{soil} \cdot HSD = 0.086\ ksf$ *(vertical buoyant soil pressure on heel)*

$(EV)_{ah} := (\sigma_{EV})_{ah} \cdot HWIDTH = 0.3\ klf$ *(vertical buoyant soil loading on heel)*

$(x_{EV})_{ah} := \frac{HWIDTH}{2} = 1.75\ ft$ *(moment arm for vertical soil loading)*

Soil Pressure Loading - Base of Heel

$L_0 := BWIDTH - BIC = \begin{bmatrix} 0.94 \\ 2.22 \end{bmatrix} ft$ *(length of base with no soil pressure loading, measured from front face of key back toward toe)*

$L := HWIDTH - L_0 = \begin{bmatrix} 2.56 \\ 1.28 \end{bmatrix} ft$ *(length of base with soil pressure loading, measured from beginning of pressure back toward connection)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{L}{(\sigma_{SP})_{heel}}$ *(similar triangles relationship between the total soil pressure load and the length of the base in compression to the length of the heel in compression to the maximum soil pressure loading at the connection)*

$(\sigma_{SP})_{heel} := \overrightarrow{-L \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} 0.27 \\ 0.16 \end{bmatrix} ksf$ *(maximum soil pressure loading at the connection of the heel)*

$SP_{heel} := \overrightarrow{0.5 \cdot (\sigma_{SP})_{heel} \cdot L} = \begin{bmatrix} 0.35 \\ 0.1 \end{bmatrix} klf$ *(resultant soil pressure loading on the heel)*

$(x_{SP})_{heel} := \frac{1}{3} L = \begin{bmatrix} 0.9 \\ 0.4 \end{bmatrix} ft$ *(moment arm for the soil pressure loading, measured from the connection of the heel)*

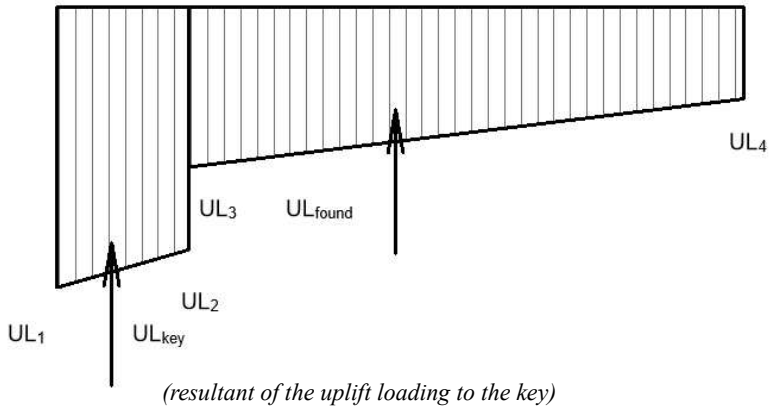
Uplifting Pressure

$UL_1 := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*



$UL_{key} := \frac{TK \cdot \langle UL_1 + UL_2 \rangle}{2} = \begin{bmatrix} 1.5 \\ 1.8 \end{bmatrix} klf$ *(resultant of the uplift loading to the key)*

$Heel\_Width := HWIDTH - TK = 2\ ft$ *(length of the heel; from the connection of the stem to the back face of the key)*

$(x_{UL})_{key} := Heel\_Width + \left(\frac{TK \cdot \langle 2 \cdot UL_1 + UL_2 \rangle}{3 \cdot \langle UL_1 + UL_2 \rangle} \right) = \begin{bmatrix} 2.75 \\ 2.76 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

$m := \frac{\langle UL_4 - UL_3 \rangle}{BWIDTH - TK} = \begin{bmatrix} -0.0421 \\ -0.0555 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship between the uplift pressure from the foundation behind the key)*

$UL_{stem} := m \cdot (HWIDTH - TK) + UL_3 = \begin{bmatrix} 0.6 \\ 0.7 \end{bmatrix} ksf$ *(uplift pressure at the stem)*

$UL_{found} := \frac{Heel\_Width \cdot \langle UL_3 + UL_{stem} \rangle}{2} = \begin{bmatrix} 1.4 \\ 1.6 \end{bmatrix} klf$ *(resultant of the uplift loading to the foundation; less the key)*

$(x_{UL})_{found} := \left(\frac{Heel\_Width \cdot \langle 2 \cdot UL_3 + UL_{stem} \rangle}{3 \cdot \langle UL_3 + UL_{stem} \rangle} \right) = \begin{bmatrix} 1.02 \\ 1.02 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

Load Combinations

Note: Forces that are oriented to the left and up are considered negative forces and moments that would rotate the heel counterclockwise are positive for the purpose of summing forces and moments.

Forces on Heel - Horizontal Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \langle (EH)_{fh} - (EH)_{bh} \rangle \\ + \langle (Hs)_{fh} - (Hs)_{bh} \rangle \end{pmatrix} = \begin{bmatrix} -1.2 \\ -0.5 \end{bmatrix} klf$ *(Summation of the forces in the horizontal direction note positive forces represent heel in compression)*

$(\Sigma F_{heelc})_{horz} := \max(LC1) = -0.5\ klf$

$(\Sigma F_{heel})_{horz} := \max\left(\overrightarrow{|LC1|}\right) = 1.2\ klf$ *(maximum of the drained vs undrained cases)*

$P\_Check :=$ if $(\Sigma F_{heelc})_{horz} > 0$
"Heel is in compression, conservatively ignore axial loads in moment capcacity check"
else
"Heel in tension, factored into moment capcacity check"

$P\_Check =$ "Heel in tension, factored into moment capcacity check"

$(\Sigma F_{heel})_{Tension} :=$ if $(\Sigma F_{heel})_{horz} > 0$ $= 0\ kip$
$0\ kip$
else
$|(\Sigma F_{heel})_{horz}| \cdot b$

Forces on Heel - Vertical Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} D + (EV)_{ah} + (Hs)_{ah} \\ + \left(UL_{key} + UL_{found}\right) + \left(SP_{heel}\right) \end{pmatrix} = \begin{bmatrix} 10.1 \\ 10.5 \end{bmatrix} klf$ *(summation of the forces in the vertical direction)*

$(\Sigma F_{heel})_{vert} := \max\left(LC1\right) = 10.5\ klf$ *(maximum of the drained vs undrained cases)*

Resultant Shear at Base

$Vu_{heel} := (\Sigma F_{heel})_{vert} = 10.5\ klf$ *(factored shear at connection of floodwall heel)*

Resultant Axial Load in Base

$(P_u)_{heel} := (\Sigma F_{heel})_{horz} = 1.2\ klf$ *(factored axial load at floodwall heel)*

$(\Sigma F_{heel})_{Tension} = 0\ ft \cdot klf$ *(tension in heel; from check above, zero if heel in compression)*

Note: Axial loads with positive values put the heel of the floodwall in compression and negative values put the heel of the floodwall in tension.

Resultant Moment - on Heel at Stem Face

$LC1_{pos} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{D \cdot (x_D)_{heel}}\right) \\ + \left(\overrightarrow{(EV)_{ah} \cdot (x_{EV})_{ah}}\right) + \left(\overrightarrow{(Hs)_{ah} \cdot (x_{Hs})_{ah}}\right) \\ + \left(\overrightarrow{(EH)_{fh} \cdot (x_{EH})_{fh}}\right) + \left(\overrightarrow{(Hs)_{fh} \cdot (x_{Hs})_{fh}}\right) \end{pmatrix} = 24.4\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{neg} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{(Hs)_{bh} \cdot (x_{Hs})_{bh}}\right) \\ + \left(\overrightarrow{(EH)_{bh} \cdot (x_{EH})_{bh}}\right) \\ + \left(\overrightarrow{SP_{heel} \cdot (x_{SP})_{heel}}\right) \\ + \left(\overrightarrow{UL_{key} \cdot (x_{UL})_{key}}\right) \\ + \left(\overrightarrow{UL_{found} \cdot (x_{UL})_{found}}\right) \end{pmatrix} = \begin{bmatrix} 22.4 \\ 21.9 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$\Sigma LC := \max\left(LC1_{pos} - LC1_{neg}\right) = 2.47\ kip$

$Mu_{heel} := \max\left(LC1_{pos} - LC1_{neg}\right) \cdot b = 2.5\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

Note: since section is under tension and flexure, heel to be designed per section B-4 of EM 1110-2-2104.

Heel Reinforcement

$Mu_{heel} = 2.5\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

$(P_u)_{heel} = 1.2\ \frac{kip}{ft}$ *(maximum factored axial tension at base of floodwall stem on the heel)*

$Vu_{heel} = 10.5\ \frac{kip}{ft}$ *(maximum factored shear at base of floodwall stem on the heel)*

Top Bars - Main Steel

$(d_b)_{heel.top} :=$ Bar Size: #8 $= 1\ in$ *(top bar size in heel)*

$(d_b)_{heel.bot} :=$ Bar Size: #8 $= 1\ in$ *(bottom bar size in heel)*

$s_{heel.top} := 12\ in$ *(top bar spacing in heel)*

$s_{heel.bot} := 12\ in$ *(bottom bar spacing in heel)*

$c_{heel.top} := 3''\ \text{cover}$ *(cover for top reinforcement in heel)*

$c_{heel.bot} := 4''\ \text{cover}$ *(cover for bottom reinforcement in heel)*

$(A_s)_{heel.top} := \frac{0.25 \cdot \pi \cdot (d_b)_{heel.top}^{\ 2} \cdot 12\ in}{s_{heel.top}} = 0.785\ in^2$ *(area of steel for top reinforcement in heel)*

$(A_s)_{heel.bot} := \frac{0.25 \cdot \pi \cdot (d_b)_{heel.bot}^{\ 2} \cdot 12\ in}{s_{heel.bot}} = 0.785\ in^2$ *(area of steel for top reinforcement in heel)*

$\rho := \frac{(A_s)_{heel.top}}{b \cdot TTOE} = 0.004$ *(reinforcement ratio for primary tension steel)*

$\rho' := \frac{(A_s)_{heel.bot}}{b \cdot TTOE} = 0.004$ *(reinforcement ratio for bottom tension steel)*

$d_{heel.top} := TTOE - c_{heel.top} - 0.5 \cdot (d_b)_{heel.top} = 14.5\ in$ *(depth to top reinforcement in heel)*

$a \cdot 0.85 \cdot f'c \cdot (d_b)_{heel.top} = (A_s)_{heel.top} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{heel.top} := \frac{(A_s)_{heel.top} \cdot (F_y)_{60} + (P_u)_{heel} \cdot b}{0.85 \cdot f'_c \cdot d_{heel.top}} = 0.87\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1)*

Axial Strength Check

$Pn_{max} := \left((A_s)_{heel.top} \cdot (F_y)_{60} + (A_s)_{heel.bot} \cdot (F_y)_{60}\right) = 94.2\ kip$ *(design axial strength, EM 1110-2-2104, Eq B-44)*

$\phi Pn := \phi_A \cdot Pn_{max} = 84.8\ kip$

$AxialCheck := Check\left((\Sigma F_{heel})_{horz} \cdot b, \phi Pn\right) = [\text{“OK”} \quad 0.01]$ *(tensile)*

Flexural Check

$\phi M_{n.Heel} := \phi_b \cdot \left(0.85 \cdot f'_c \cdot a_{heel.top} \cdot b \cdot \left(d_{heel.top} - \frac{a_{heel.top}}{2}\right) - (P_u)_{heel} \cdot \left(d_{heel.top} - \frac{TTOE}{2}\right) \cdot b\right) = 41.7\ kip \cdot ft$

(moment capacity for beam in flexure and axial tension, EM 2104, Eq D-1)

$(M_{Flex\_Axial})_{Heel} := Check\left(Mu_{heel}, \phi M_{n.Heel}\right) = [\text{“OK”} \quad 0.1]$

Minimum Required Steel for Flexure

Given

Constraints

Values

$As_{req} := 1.5\ in^2$

$Mu_{heel} = \phi_b \cdot \left(\left(As_{req} \cdot (F_y)_{60} \cdot \left(d_{heel.top} - \frac{As_{req} \cdot (F_y)_{60} + (P_u)_{heel} \cdot b}{0.85 \cdot f'_c \cdot d_{heel.top}}\right)\right) - \left((P_u)_{heel} \cdot \left(d_{heel.top} - \frac{TTOE}{2}\right) \cdot b\right)\right)$

Solver

$As_{req.stem} := \text{find}\left(\mathbf{As_{req}}\right) = 0.046\ in^2$

(minimum steel required for flexural strength)

$(A_{s.min})_{heel.top} := As_{req.stem} = 0\ in^2$

Minimum Required Steel per ACI

$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.584\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{heel.top} = 0.58\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

temperature and shrinkage reinforcement

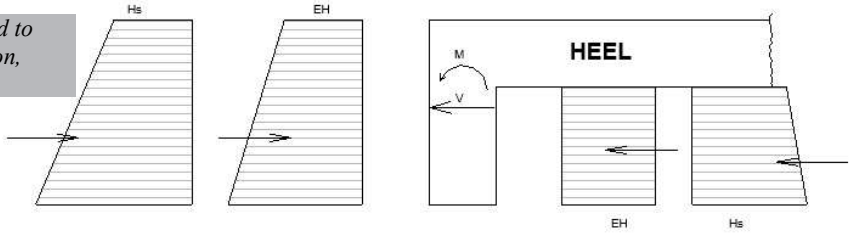
KEY DESIGN

Loads to Key

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last

$HK = 3\ ft$ *(depth of key, from bottom of foundation down)*

$THEEL = 4.5\ ft$ *(depth of key, from top of foundation down)*



Hydrostatic Loads - Front of Key

Note: hydrostatic loads applied in two directions, notated as fk = front of key and bk = back of key

$(\sigma_{Hs})_{fk1} := \gamma_{water} \cdot (HTS + TTOE) = 0.468\ ksf$ *(horizontal water loading, top of key)*

$(\sigma_{Hs})_{fk2} := \gamma_{water} \cdot (HTS + THEEL) = 0.655\ ksf$ *(horizontal water loading, bottom of key)*

$(Hs)_{fk} := \frac{HK \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})}{2} = 1.7\ klf$ *(hydrostatic loading to the front of key)*

$(x_{Hs})_{fk} := \frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{fk2}) + (\sigma_{Hs})_{fk1})}{3 \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})} = 1.58\ ft$ *(moment arm for hydrostatic loading, measured down from key connection to foundation)*

Hydrostatic Loads - Back of key

$(\sigma_{Hs})_{bk.top} := (\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.537 \\ 0.611 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bk.bot} := (\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.554 \\ 0.635 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(Hs)_{bk} := \frac{HK \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{2} = \begin{bmatrix} 1.6 \\ 1.9 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of the key)*

$(x_{Hs})_{bk} := \left(\frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{3 \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})} \right) = \begin{bmatrix} 1.5 \\ 1.5 \end{bmatrix} ft$ *(moment arm of the hydrostatic loading to the front face of the key, measured down from the connection to foundation)*

Lateral Earth Pressures - Face of Key

$(\sigma_{EH})_{fk.top} := \gamma'_{soil} \cdot k_0 \cdot (HTS + TTOE) = 0.229\ ksf$ *(min horizontal lateral earth loading, top of foundation)*

$(\sigma_{EH})_{fk.bot} := \gamma'_{soil} \cdot k_0 \cdot (HTS + THEEL) = 0.321\ ksf$ *(min horizontal lateral earth loading, bottom of foundation)*

$THEEL = 4.5\ ft$ *(depth of applied loading)*

$(EH)_{fk} := \frac{HK \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{2} = 0.8\ klf$ *(resultant of the lateral earth loading to the front face of key)*

$(x_{EH})_{fk} := \frac{HK \cdot (2 \cdot (\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{3 \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})} = 1.583\ ft$ *(moment arm of the lateral earth loading to to the front face of the key, measured from the the connection of the key to the foundation)*

Lateral Earth Pressures - Back of Key

$(\sigma_{EH})_{bk.top} := (\sigma_{EH})_{bh.top} = \begin{bmatrix} 0.649 \\ 0.428 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bk.bot} := (\sigma_{EH})_{bh.bot} = \begin{bmatrix} 0.649 \\ 0.428 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 3\ ft$ *(depth of key from the back side face)*

$(EH)_{bk} := \frac{HK \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{2} = \begin{bmatrix} 1.9 \\ 1.3 \end{bmatrix} klf$ *(resultant of the lateral earth loading to the back face of key)*

$(x_{EH})_{bk} := \frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{3 \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)} = \begin{bmatrix} 1.5 \\ 1.5 \end{bmatrix} ft$ *(moment arm for the lateral earth loading to the back face of the key, measured from the connection of the key to the foundation)*

Resultant Moment - on Toe

$LC1_{fk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{fk} \cdot (x_{EH})_{fk}}\right) + \left(\overrightarrow{(Hs)_{fk} \cdot (x_{Hs})_{fk}}\right)\right) = 6.4\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{bk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{bk} \cdot (x_{EH})_{bk}}\right) + \left(\overrightarrow{(Hs)_{bk} \cdot (x_{Hs})_{bk}}\right)\right) = \begin{bmatrix} 8.6 \\ 7.6 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$LC1_{key} := LC1_{bk} - LC1_{fk} = \begin{bmatrix} 2.3 \\ 1.2 \end{bmatrix} \frac{kip \cdot ft}{ft}$

$Mu_{key} := \max\left(LC1_{bk} - LC1_{fk}\right) \cdot 1\ ft = 2.3\ kip \cdot ft$ *(factored maximum moment at connection of floodwall key to the heel)*

Key Reinforcement

Back Bars - Main Steel

$(d_b)_{key.main} :=$ Bar Size: #8 $= 1\ in$ *(main bar size in key)*

$s_{key.main} := 12\ in$ *(main bar spacing in key)*

$c_{key.main} :=$ 4″ cover *(cover for main reinforcement in key)*

$(A_s)_{key.main} := \frac{0.25 \cdot \pi \cdot (d_b)_{key.main}^{\ 2} \cdot 12\ in}{s_{key.main}} = 0.785\ in^2$ *(area of steel for top reinforcement in key)*

$d_{key.main} := TTOE - c_{key.main} - 0.5 \cdot (d_b)_{key.main} = 13.5\ in$ *(depth to main reinforcement in key)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{key.main} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot \left(f'_c - 4000\ psi\right)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.8$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{key.main} := \frac{(A_s)_{key.main} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{key.main}} = 0.9\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1)*

$(\phi M_n)_{key.main} := \phi_b \cdot (A_s)_{key.main} \cdot (F_y)_{60} \cdot \left(d_{key.main} - \frac{a_{key.main}}{2}\right) = 46.1\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{key} := Check\left(Mu_{key}, (\phi M_n)_{key.main}\right) = [\text{“OK”} \quad 0.05]$ *(nominal flexural check, utilization ratio)*

Minimum Required Steel for Flexure

Solve Constraints Values

$$As_{req} := 1.5\ in^2$$

$$Mu_{key} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{key.main} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{key.main}}\right)$$

$$As_{req.stem} := \text{find}\left(As_{req}\right) = 0.037\ in^2$$

$$(A_{s.min})_{key.min} := As_{req.stem} = 0\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{key.main} = 0.5\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{key.main} = 0.5\ in^2$$

(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.003 \cdot \left(\frac{TK \cdot b}{2}\right) = 0.324\ in^2$$

(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$

(minimum area of steel required for flexural capacity)

$$A_{s.min} = 0.543\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{key.min} \cdot \frac{4}{3} = 0\ in^2$$

(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)

$$(A_s)_{key.req} := \text{if } A_{s\_1.3} < (A_s)_{key.main} \ \| \ as \leftarrow (A_{s.min})_{key.min} \ \text{else} \ \| \ as \leftarrow A_{s.min} = 0.037\ in^2$$

(required steel to meet steel requirements)

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{key.main} = 0.8\ in^2$$

(area of steel provided in the horizontal direction for the heel)

$$(Steel\_Check_{Top})_{key} := Check\left((A_s)_{key.req}, (A_s)_{key.main}\right) = [\text{“OK”} \quad 0.05]$$

U.S.ARMY CORPS OF ENGINEERS - KANSAS CITY DISTRICT

T-Wall Load Cases and Strength Design

Upper Turkey Creek

Merriam, KS

ASSUMPTIONS

- Strength Design Loading conditions and load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

FLOOD LOAD CASES

Unusual Case

Top of Wall, ACE = 100 year event, Unusual Case

WSE = Top of Protection

Usual Case

ACE = 10 year event, Usual Case

WSE elevation below the top of the foundation

Note: The Unusual Flood Case with water to the top of the wall governs the design of this floodwall. Non-flood condition loads such as construction, seismic and wind are addressed in the stem design; however, it is apparent that the top of wall flood condition governs stability and the primary steel design so only the Unusual top of wall flood load is considered for stability and the base design.

The Usual Flood Case does not have water to the top of the foundation and is not included in these calculations.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$\gamma'_{soil} := \gamma_{soil} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$q_n := 2000\ psi$ *(bearing pressure, Reference DDR Table 9.2)*

Drained Soil Conditions

$\phi_{drained} := 28\ deg$ *(internal friction angle for drained soil condition)*

$C_{drained} := 0\ psf$ *(cohesion for drained soil condition)*

$k_0 := 1 - \sin\left(\phi_{drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

Undrained Soil Conditions

$\phi_{undrained} := 0\ deg$ *(internal friction angle for drained soil condition)*

$C_{undrained} := 1000\ psf$ *(cohesion for drained soil condition)*

$(k_0)_{undrained} := 1 - \sin\left(\phi_{undrained}\right) = 1$ *(at-rest soil pressure coefficient for the undrained condition)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(young's modulus of elasticity for steel)*

$(F_y)_{30} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$(F_y)_{60} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$\varepsilon_{ty} := \frac{(F_y)_{60}}{E_{steel}} = 0.0021$ *(yield strain of 60 ksi steel)*

Concrete Properties

$f'_c := 4500\ psi$ *(concrete compressive strength for all structures)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength for all structures)*

$q\lambda_c := 1.0$ *(concrete modification factor)*

$cover_3 := 3\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$cover_4 := 4\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$\gamma_{conc} := 150\ pcf$ *(concrete unit weight)*

$Ec := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$ *(young's modulus of elasticity for concrete)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

Load Factors

Serviceability Load Factors

Note: the unusual loading condition is used for the top of the floodwalls since they are designed to the 100 year event. the usual loading condition is defined as the 10 year event.

$(\gamma_p)_{Serve.u} := 2.2$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

$(\gamma_p)_{Serve.n} := 1.6$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-4)*

Strength Limit States

$\phi_b := 0.9$ *(bending load reduction factor - ACI 318-19 21.2.2, Table 21.2.2)*

$\phi_A := 0.9$

$\phi_V := 0.75$ *(shear load reduction factor - ACI 318-19 Table 21.2.1)*

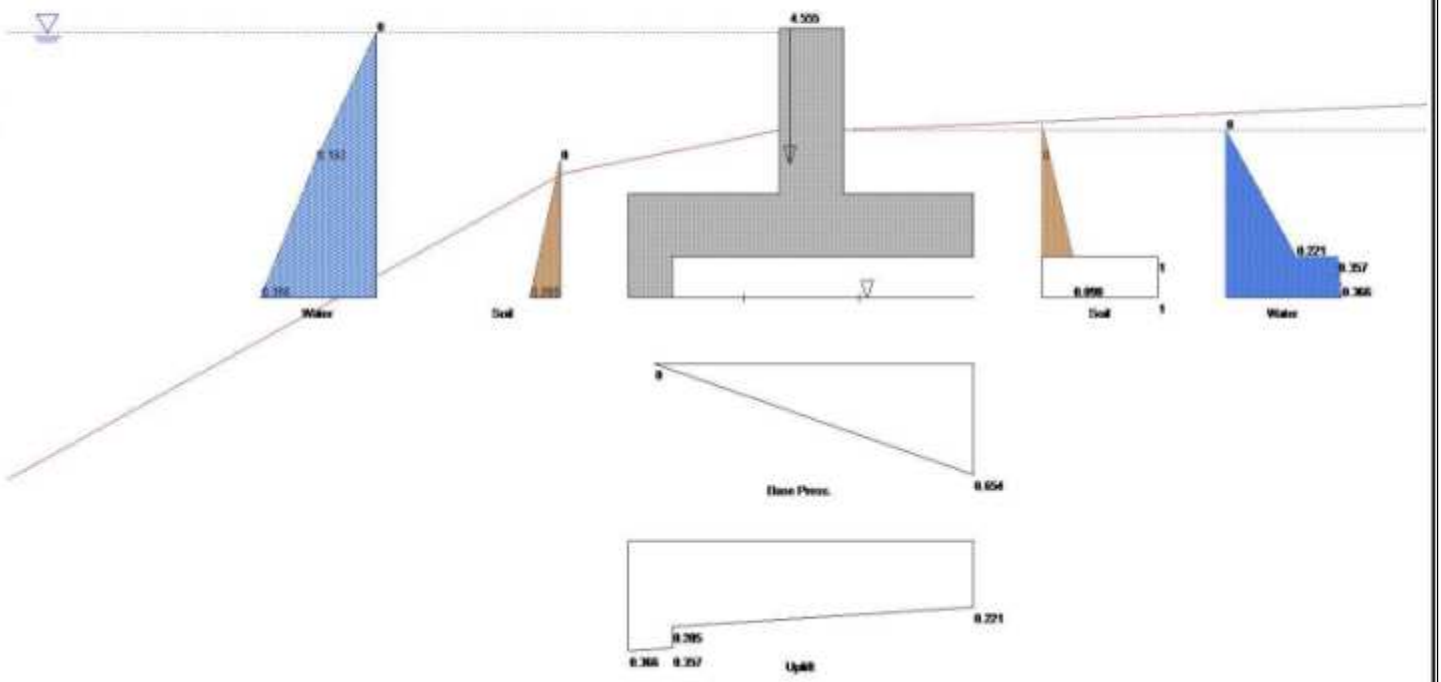
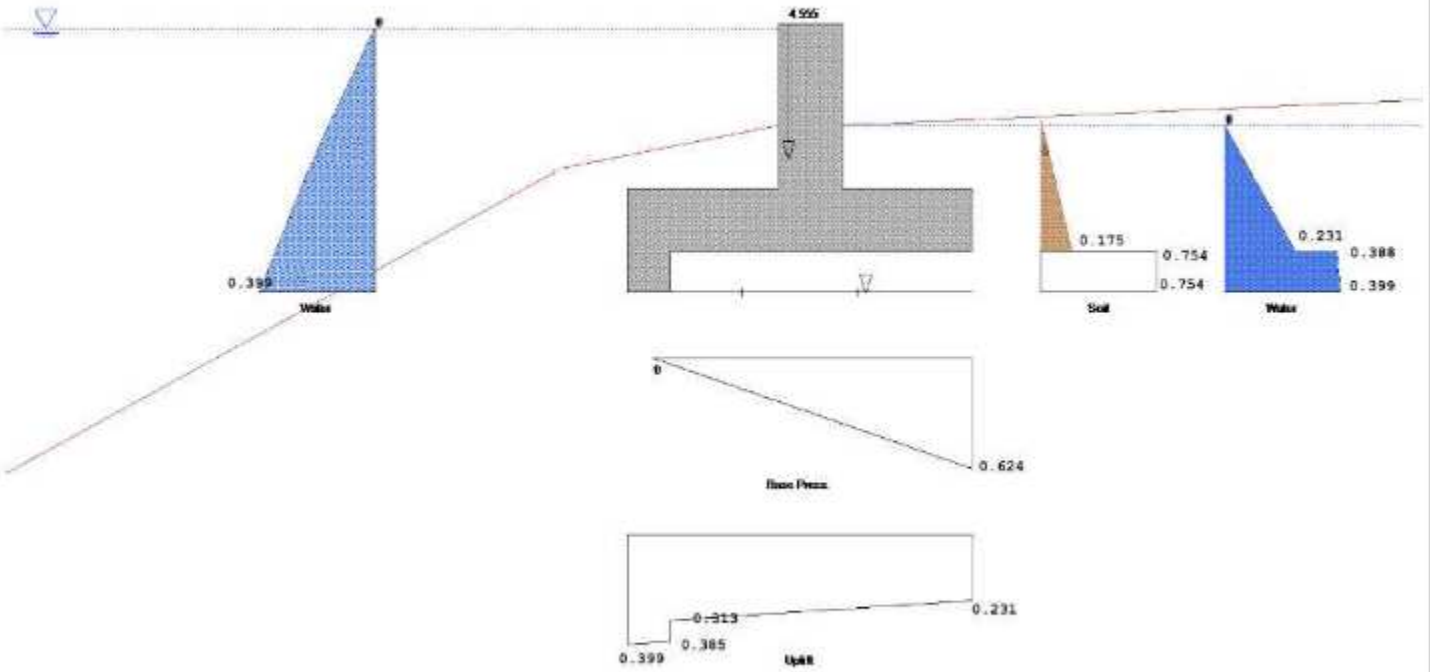
CT Wall - Drained Case Output



CT Wall - Undrained Case Output



CTWALL OUTPUT

Lateral Earth Loading

$\sigma_{EHd} := \begin{bmatrix} 0.0949 \\ 0 \end{bmatrix} ksf$ *(lateral earth pressure loading to driving side, bottom of key; Drained, Undrained)*

$\sigma_{EHr} := \begin{bmatrix} 0.098 \\ 0.175 \end{bmatrix} ksf$ *(lateral earth pressure loading to resisting side, bottom of foundation at toe; Drained, Undrained)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} := \begin{bmatrix} 1.02 \\ 0.754 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation; Drained, Undrained)*

$(\sigma_{EH})_{bh.bot} := \begin{bmatrix} 1.02 \\ 0.754 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key, Drained, Undrained)*

Impact Loading

$IM := 0.1\ klf$ *(impact loading to the top of the wall)*

Soil Pressure

$(\sigma_{SP})_{max} := -\begin{bmatrix} 0.654 \\ 0.624 \end{bmatrix} ksf$ *(max base soil loading from CT Wall Output)*

Uplift Pressure

$UL_1 := \begin{bmatrix} 0.366 \\ 0.399 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 0.357 \\ 0.388 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.285 \\ 0.313 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.221 \\ 0.231 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$(\sigma_{UL})_{min} := UL_4 = \begin{bmatrix} 0.221 \\ 0.231 \end{bmatrix} ksf$ *(minimum uplift pressure at the end of the toe)*

$(\sigma_{UL})_{max} := UL_3 = \begin{bmatrix} 0.285 \\ 0.313 \end{bmatrix} ksf$ *(maximum uplift pressure behind the key)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} := \begin{bmatrix} 0.357 \\ 0.388 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

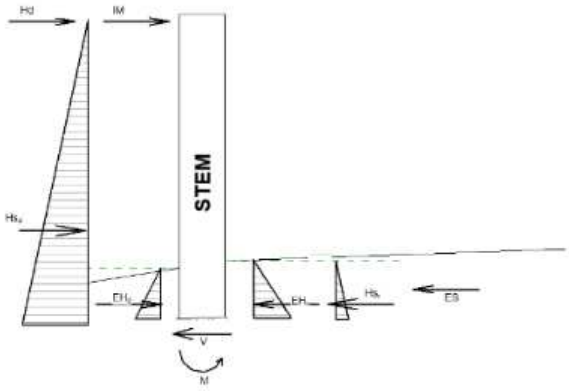
$(\sigma_{Hs})_{bh.bot} := \begin{bmatrix} 0.366 \\ 0.399 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

STEM DESIGN, RIVER SIDE

Loads to Stem

Note: largest loading from drained and undrained cases used to determine the controlling load case. In each loading condition, drained loads are listed first and undrained last.

This design for the riverside steel, along with the EnerCalc calculations, attached will be used for the landside steel design for simplicity. By inspection, the riverside reinforcement is sufficient for the landside reinforcement design.



Hydrostatic Loads

$$\sigma_{Hsd} := \begin{bmatrix} \gamma_{water} \cdot HTS \\ \gamma_{water} \cdot HTS \end{bmatrix} = \begin{bmatrix} 249.6 \\ 249.6 \end{bmatrix} psf$$ *(hydrostatic pressure loading to driving side)*

$$Hs_d := \overrightarrow{0.5 \cdot \sigma_{Hsd} \cdot HTS} = \begin{bmatrix} 0.499 \\ 0.499 \end{bmatrix} klf$$ *(hydrostatic loading to driving side)*

$$(x_{Hs})_d := HTS \cdot \frac{1}{3} = 1.3\ ft$$ *(moment arm for hydrostatic loading to the driving side from the base of the stem)*

Note: assume that hydrostatic loading from the resisting side of the T-wall provided from groundwater up to the ground surface. Assume that all additional water from the resisting side, landside, of the floodwall is conveyed away through interior drainage systems.

$$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 96.7 \\ 96.7 \end{bmatrix} psf$$ *(hydrostatic pressure loading to resisting side)*

$$Hs_r := \overrightarrow{0.5 \cdot \sigma_{Hsr} \cdot HSR} = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$$ *(hydrostatic loading to resisting side)*

$$(x_{Hs})_r := HSR \cdot \frac{1}{3} = 0.52\ ft$$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Lateral Earth Loading

$$(\sigma_{EHd})_{stem} := \sigma_{EHd} \cdot \left(\frac{HSD}{HSD + THEEL} \right) = \begin{bmatrix} 0.036 \\ 0 \end{bmatrix} ksf$$ *(lateral earth pressure loading to driving side of stem)*

$$EH_d := \overrightarrow{0.5 \cdot (\sigma_{EHd})_{stem} \cdot HSD} = \begin{bmatrix} 0 \\ 0 \end{bmatrix} klf$$ *(lateral earth loading to driving side of stem)*

$$(x_{EH})_d := HSD \cdot \frac{1}{3} = 0.5\ ft$$ *(moment arm for lateral earth loading to the driving side from the base of the stem)*

$$(\sigma_{EHr})_{stem} := \sigma_{EHr} \cdot \frac{HSR}{HSR + TTOE} = \begin{bmatrix} 0.05 \\ 0.089 \end{bmatrix} ksf$$ *(lateral earth pressure loading to resisting side of stem)*

$$EH_r := \overrightarrow{0.5 \cdot (\sigma_{EHr})_{stem} \cdot HSR} = \begin{bmatrix} 0 \\ 0.1 \end{bmatrix} klf$$ *(lateral earth loading to resisting side of stem)*

$$(x_{EH})_r := HSR \cdot \frac{1}{3} = 0.5\ ft$$ *(moment arm for lateral earth loading to the resisting side from the base of the stem)*

Impact Loading

Note: reference DDR for discussion of impact loading on floodwalls.

$$IM := 0.1\ klf$$ *(impact loading to the top of the wall)*

$$(x_{IM})_d := HTS = 4\ ft$$ *(moment arm of the impact load from the base of the stem)*

Operating Equipment

$$p_{const} := 250\ psf$$ *(construction surcharge loading)*

Note: assume that the surcharge loading is uniform and that the resultant is mid-height of the soil depth.

$$d_{soil} := HSR = 1.6\ ft$$ *(depth of soil cover on stem)*

$$(x_Q)_d := \frac{HSR}{2} = 0.8\ ft$$ *(resultant height above base of stem)*

$$x_Q := d_{soil} - (x_Q)_d = 0.8\ ft$$ *(depth from resultant to top of soil)*

$\sigma_H := p_{const} \cdot k_0 = 0.133\ ksf$ *(lateral linear pressure applied to wall)*

$Q := \sigma_H \cdot HSR = 0.206\ klf$ *(lateral surcharge load to structure, usual case)*

Wind

Note: for conservative analysis, wind loading only applied to the driving side as a positive pressure or applied to the resisting side as a negative pressure.

$(p_w)_p := 30.4\ psf$ *(primary wind pressure, reference DDR)*

$(p_w)_c := 15.8\ psf$ *(companion wind pressure, reference DDR)*

$G := 0.85\ \frac{1}{ft}$ *(gust factor, ASCE 7-16 Section 26.11.1)*

$C_f := 1.3$ *(force coefficient from ASCE 7-16, figure 29.3-1, s/h = 1 and B/s = '>45')*

$d := HTS - HSR = 2.4\ ft$ *(exposed surface of the stem for wind pressure)*

$A_s := 1\ ft \cdot d = 2.4\ ft^2$ *(exposed surface area of the wall per linear foot)*

$W_c := (p_w)_c \cdot G \cdot C_f \cdot A_s = 0.043\ klf$ *(wind loading, usual case for companion loading)*

$W_p := (p_w)_p \cdot G \cdot C_f \cdot A_s = 0.082\ klf$ *(wind loading, unusual case)*

$(x_W)_d := HTS - \frac{d}{2} = 2.8\ ft$ *(resultant height above base of stem)*

Earthquake Loading: Equivalent Lateral Force

$D_{wall} := (TTS \cdot HTS) \cdot \gamma_{conc} = 0.9\ \frac{1}{ft} \cdot kip$ *(dead load of the stem of the wall)*

$I_e := 1.5$ *(importance factor, ASCE 7-16 Table 1.5-2)*

$R := 2.5$ *(response modification factor, ASCE 7-16, Table 12.2-1, Item G.3)*

$S_{DS} := 0.101$ *(seismic spectral acceleration for short period)*

$Cs := \frac{S_{DS}}{\frac{R}{I_e}} = 0.1$ *(seismic response coefficient, ASCE 7-16 12.8-2)*

$V := Cs \cdot D_{wall} = 0.1\ klf$ *(seismic base shear, ASCE 7-16, EQ 12.8-1)*

$EQ := V = 0.1\ klf$

$(x_{EQ}) := HSR = 1.6\ ft$ *(resultant height above base of stem)*

Load Combinations

Note: Usual design cases not considered here as the Usual pool level does not reach the base of the stem.

Driving Side Forces

$LC1_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Hs_d + IM) = \begin{bmatrix} 1 \\ 1 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot (EH_d + EQ) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot (EH_d + Q) = \begin{bmatrix} 0.4 \\ 0.3 \end{bmatrix} klf$ *(load case 3 for construction)*

Resisting Side Forces

$LC1_r := (\gamma_p)_{Serve.n} \cdot (EH_r + Hs_r - W_c) = \begin{bmatrix} 0.1 \\ 0.2 \end{bmatrix} klf$ *(load case 1 for maximum hydrostatic)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(load case 2a,2b for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot (EH_r) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} klf$ *(load case 4 for construction)*

Resultant Shear at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 0.9 \\ 0.8 \end{bmatrix} klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.1 \\ 0 \end{bmatrix} klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.3 \\ 0.2 \end{bmatrix} klf$ *(equilibrium load case 3)*

$\Sigma F_{stem} := \text{stack}(LC1, LC2, LC3)$

Note: Maximum factored shear loading to the stem is the governing loading for the river side steel design. Minimum factored shear loading is the governing landside steel design.

$(Vu)_{stem} := \max(\Sigma F_{stem}) = 0.9\ klf$ *(resultant factored shear at base of floodwall stem, driving side)*

Resultant Moment - Driving Side

$LC1_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d\right) + \left(Hs_d \cdot (x_{Hs})_d\right) + IM \cdot (x_{IM})_d\right) = \begin{bmatrix} 1.7 \\ 1.7 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum hydrostatic)*

$LC2_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d\right) + \left(EQ \cdot (x_{EQ})\right)\right) = \begin{bmatrix} 0.2 \\ 0.1 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_d := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_d \cdot (x_{EH})_d\right) + \left(Q \cdot \left((x_Q)_d\right)\right)\right) = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction)*

Resultant Moment - Resisting Side

$LC1_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r\right) + \left(Hs_r \cdot (x_{Hs})_r\right)\right) = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 1 for maximum flooding)*

$LC2_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r\right)\right) = \begin{bmatrix} 0.03 \\ 0.06 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 2 for earthquake loading)*

$LC3_r := (\gamma_p)_{Serve.n} \cdot \left(\left(EH_r \cdot (x_{EH})_r\right)\right) = \begin{bmatrix} 0.03 \\ 0.06 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case 3 for construction or surcharge loading)*

Resultant Moment at Base

$\Sigma F = V - \Sigma F_d + \Sigma F_r$ *(equilibrium equation)*

$LC1 := LC1_d - LC1_r = \begin{bmatrix} 1.6 \\ 1.6 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 1)*

$LC2 := LC2_d - LC2_r = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 2)*

$LC3 := LC3_d - LC3_r = \begin{bmatrix} 0.2 \\ 0.2 \end{bmatrix} ft \cdot klf$ *(equilibrium load case 3)*

$\Sigma M_{stem} := \text{stack}(LC1, LC2, LC3)$ *(resultant factored moment at base of floodwall stem)*

$(Mu)_{stem} := \max(\Sigma M_{stem}) \cdot 1\ ft = 1.6\ kip \cdot ft$ *(resultant moment at base of floodwall stem, riverside steel design)*

Design Check Function

(system check for capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing arrays)

$$Check_v\left(X_U, X_N\right) := \left\| \begin{array}{l} \text{for } i \in \mathbf{ORIGIN} .. \text{last}\left(X_U\right) \\ \quad \left\| \begin{array}{l} \text{if } X_{U_i} > X_{N_i} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“NO GOOD”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \\ \text{else if } X_{N_i} = 0 \\ \quad \left\| ch_{i,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{i,1} \leftarrow \text{“OK”} \\ ch_{i,2} \leftarrow \dfrac{X_{U_i}}{X_{N_i}} \end{array} \right. \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

(if the capacity is zero, used for error handling)

(if the required is less than the capacity)

(user defined function to check the design capacity against the required capacity, function for use with comparing scalar values)

$$Check\left(X_U, X_N\right) := \left\| \begin{array}{l} \text{if } X_U > X_N \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“NO GOOD”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ \text{else if } X_U = 0 \\ \quad \left\| ch_{1,1} \leftarrow \text{“N/A”} \right. \\ \text{else} \\ \quad \left\| \begin{array}{l} ch_{1,1} \leftarrow \text{“OK”} \\ ch_{1,2} \leftarrow \dfrac{X_U}{X_N} \end{array} \right. \\ ch \end{array} \right.$$

(if the required is greater than the capacity)

Minimum Required Steel per ACI

$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.584\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{stem.vert} = 0.58\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTS \cdot b) = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.584\ in^2$

$A_{s\_1.3} := (A_{s.min})_{stem.ten} \cdot \frac{4}{3} = 0.033\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{stem.req} := \text{if } A_{s\_1.3} < (A_s)_{stem.vert} \quad as \leftarrow (A_{s.min})_{stem.ten} \quad \text{else} \quad as \leftarrow A_{s.min} = 0.025\ in^2$
(required steel to meet steel requirements)
(includes ACI 318-19 9.6.1.2(a) and (b))
(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{stem.vert} = 0.8\ in^2$ *(area of steel provided in the vertical direction for the stem)*

$(Steel\_Check_{Vert})_{Stem} := Check\left((A_s)_{stem.req}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.03]$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$(Steel\_Check_{Vert.ts})_{Stem} := Check\left((A_{s.min})_{temp}, (A_s)_{stem.vert}\right) = [\text{"OK"} \quad 0.4]$ *(check stem reinforcement to temperature and shrinkage requirements)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{stem.vert}}{\left(b \cdot d_{stem.vert}\right)} = 0.0045$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{Stem} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{stem.lat} :=$ Bar Size: #6 $= 0.75\ in$ *(lateral bar size in stem)*

$s_{stem.lat} := 12\ in$ *(lateral bar spacing in stem)*

$(A_s)_{stem.lat} := \frac{0.25 \cdot \pi \cdot (d_b)_{stem.lat}^{\ 2} \cdot 12\ in}{s_{stem.lat}} = 0.442\ in^2$ *(area of steel lateral reinforcement in stem)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} := \frac{0.003 \cdot \left(TTS \cdot b\right)}{2} = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$A_{s.req} := (A_{s.min})_{temp} = 0.3\ in^2$

$(A_s)_{stem.lat} = 0.4\ in^2$ *(area of steel provided in the lateral direction for the stem)*

$(Steel\_Check_{Lat})_{Stem} := Check\left(A_{s.req}, (A_s)_{stem.lat}\right) = [\text{"OK"} \quad 0.7]$ *(check stem reinforcement to required reinforcement)*

Riverside Reinforcement

Primary Reinforcement

$(d_b)_{stem.vert} = 1\ in$ *bars located at* $s_{stem.vert} = 12\ in$ *centers*

Lateral Reinforcement

$(d_b)_{stem.lat} = 0.75\ in$ *bars located at* $s_{stem.lat} = 12\ in$ *centers*

Deflection Check

Note: Reference provided justification file for loading conditions and attached EnerCalc calculations for the deflections in floodwall stem since stem thickness is less than H/8. From EnerCalc report, wall deflections limited to H/6838, which is less than expected movement capacity in waterstop and wall joints. 4 ft tall floodwalls to have stems with above detailed reinforcement.

Landside Reinforcement

For design simplicity, landside reinforcement to match both primary and lateral reinforcement.

STEM SHEAR CONNECTION TO FOUNDATION

Shear Friction

$f_y := (F_y)_{60} = 60000\ psi$ *(yield strength of reinforcing steel)*

$\mu := 1.0$

$(d_b)_{stem.vert.2} :=$ Bar Size: #6 $= 0.75\ in$ *(vertical bar size in stem)*

$s_{stem.vert2} := 12\ in$

$A_{vf} := \left(\frac{\pi}{4}\right) \cdot (d_b)_{stem.vert.2}{}^2 \cdot \left(\frac{b}{s_{stem.vert2}}\right) = 0.4\ in^2$

$V_n := \mu \cdot A_{vf} \cdot f_y = 26.5\ kip$ *(shear-friction strength, ACI 318-19, eq 22.9.4.2)*

Table 22.9.4.2—Coefficients of friction

Contact surface condition	Coefficient of friction μ[1]	
Concrete placed monolithically	1.4λ	(a)
Concrete placed against hardened concrete that is clean, free of laitance, and intentionally roughened to a full amplitude of approximately 1/4 in.	1.0λ	(b)
Concrete placed against hardened concrete that is clean, free of laitance, and not intentionally roughened	0.6λ	(c)
Concrete placed against as-rolled structural steel that is clean, free of paint, and with shear transferred across the contact surface by headed studs or by welded deformed bars or wires.	0.7λ	(d)

[1]λ = 1.0 for normalweight concrete. For lightweight concrete, λ is calculated as given in 19.2.4, but shall not exceed 0.85.

Table 22.9.4.4—Maximum V_n across the assumed shear plane

Condition	Maximum V_n		
Normalweight concrete placed monolithically or placed against hardened concrete intentionally roughened to a full amplitude of approximately 1/4 in.	Least of (a), (b), and (c)	$0.2f'_cA_c$	(a)
		$(480 + 0.08f'_c)A_c$	(b)
		$1600A_c$	(c)
Other cases	Lesser of (d) and (e)	$0.2f'_cA_c$	(d)
		$800A_c$	(e)

Maximum Shear Friction

$A_c := b \cdot TTS = 1.5\ ft^2$

$(V_n)_a := 0.2\ f'_c \cdot A_c = 194.4\ kip$ *(shear-friction maximum, equation a, Table 22.9.4.4)*

$(V_n)_b := \left(480\ psi + 0.08 \cdot f'_c\right) \cdot A_c = 181.4\ kip$ *(shear-friction maximum, equation b, Table 22.9.4.4)*

$(V_n)_c := \left(16000\ psi\right) A_c = 3456\ kip$ *(shear-friction maximum, equation c, Table 22.9.4.4)*

$(V_n)_{max} := \max\left((V_n)_a, (V_n)_b, (V_n)_c\right) = 3456\ kip$ *(shear-friction maximum, Table 22.9.4.4)*

Shear Strength

$\phi_V = 0.75$ *(reduction factor for shear capacity)*

$\phi_V V_n := \phi_V \cdot min\left((V_n)_{max}, V_n\right) = 19.9\ kip$ *(factored shear-friction strength)*

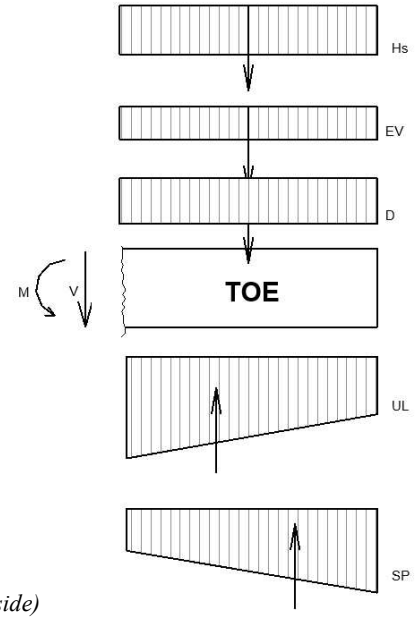
$V_{stem} := (Vu)_{stem} \cdot b = 0.9\ kip$ *(calculated shear required at base of stem)*

$V_{check} := Check\left(V_{stem}, \phi_V V_n\right) = [\text{“OK”} \quad 0.04]$ *(shear check, utilization ratio)*

Toe Check

Loads to Toe

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



Dead Load

$\sigma_D := \gamma_{conc} \cdot TTOE = 225\ psf$

$D := \sigma_D \cdot TWIDTH = 0.7\ klf$ *(resultant dead load of toe)*

$(x_D)_{toe} := \frac{TWIDTH}{2} = 1.5\ ft$ *(moment arm of the dead loading from the connection of the toe to the foundation)*

Hydrostatic Loads Above Toe

Note: Groundwater assumed to the soil surface. Potential additional seepage pressure conservatively ignored.

$\sigma_{Hsr} := \begin{bmatrix} \gamma_{water} \cdot HSR \\ \gamma_{water} \cdot HSR \end{bmatrix} = \begin{bmatrix} 96.7 \\ 96.7 \end{bmatrix} psf$ *(hydrostatic pressure loading to resisting side)*

$Hs_r := \overrightarrow{TWIDTH \cdot \sigma_{Hsr}} = \begin{bmatrix} 0.3 \\ 0.3 \end{bmatrix} klf$ *(Resultant hydrostatic loading to resisting side)*

$(x_{Hs})_r := TWIDTH \cdot 0.5 = 1.5\ ft$ *(moment arm for hydrostatic loading to the resisting side from the base of the stem)*

Vertical Earth Pressure

$\sigma_{EV} := \gamma'_{soil} \cdot HSR = 89.3\ psf$

$EV_r := \begin{bmatrix} \sigma_{EV} \cdot TWIDTH \\ \sigma_{EV} \cdot TWIDTH \end{bmatrix} = \begin{bmatrix} 0.268 \\ 0.268 \end{bmatrix} klf$ *(buoyant force of vertical soil loading)*

$(x_{EV})_r := \frac{TWIDTH}{2} = 1.5\ ft$

Soil Pressure

$(\sigma_{SP})_{max} = \begin{bmatrix} -0.654 \\ -0.624 \end{bmatrix} ksf$ *(max soil loading from CT Wall Output)*

$BWIDTH = 8\ ft$ *(total length of base of wall)*

$BIC_{percent} := \begin{bmatrix} 89.61 \\ 75.35 \end{bmatrix}\%$ *(percent of the base in compression)*

$BIC := BWIDTH \cdot BIC_{percent} = \begin{bmatrix} 7.2 \\ 6 \end{bmatrix} ft$ *(length of base in compression)*

$TWIDTH = 3\ ft$ *(length of toe of the foundation)*

note: using the length of the toe to determine the soil loading at the the connection of the toe to the stem and heel, use similar triangles to determine the loading at the connection of the toe.

$NTWIDTH := BIC - TWIDTH = \begin{bmatrix} 4.2 \\ 3 \end{bmatrix} ft$ *(length of the not-toe of the foundation in compression)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{NTWIDTH}{(\sigma_{SP})_1}$ *(relationship of similar triangles)*

$(\sigma_{SP})_1 := \overrightarrow{NTWIDTH \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} -0.38 \\ -0.31 \end{bmatrix} ksf$ *(soil pressure loading at the connection of the toe)*

$SP_{toe} := \frac{TWIDTH \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)}{2} = \begin{bmatrix} -1.6 \\ -1.4 \end{bmatrix} klf$ *(resultant soil loading to the toe of the foundation)*

$$(x_{SP})_{toe} := \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{SP})_{max}\right) + (\sigma_{SP})_1\right)}{3 \cdot \left((\sigma_{SP})_{max} + (\sigma_{SP})_1\right)} = \begin{bmatrix} 1.6 \\ 1.7 \end{bmatrix} ft$$

(moment arm from the connection of the toe to the resultant of the soil pressure loading)

Uplift Pressures

$$(\sigma_{UL})_{min} = \begin{bmatrix} 0.221 \\ 0.231 \end{bmatrix} ksf$$

(minimum uplift pressure at the end of the toe)

$$(\sigma_{UL})_{max} = \begin{bmatrix} 0.285 \\ 0.313 \end{bmatrix} ksf$$

(maximum uplift pressure behind the key)

Note: Uplift pressure drops off linearly from the back of the key to the toe of the foundation

$$BWIDTH = 8\ ft$$

(foundation width)

$$TK = 1\ ft$$

(key width)

$$L := BWIDTH - TK = 7\ ft$$

(length of linear uplift pressure)

$$(\sigma_{UL})_{max} - (\sigma_{UL})_{min} = m(L)$$

(linear relationship)

$$m := \frac{(\sigma_{UL})_{max} - (\sigma_{UL})_{min}}{L} = \begin{bmatrix} 0.0091 \\ 0.0117 \end{bmatrix} \frac{ksf}{ft}$$

(linear relationship)

$$(\sigma_{UL})_{max.toe} := \overrightarrow{(m \cdot TWIDTH) + (\sigma_{UL})_{min}} = \begin{bmatrix} 0.248 \\ 0.266 \end{bmatrix} ksf$$

(uplift pressure at the connection of the toe to the foundation)

$$UL_{toe} := \frac{-TWIDTH \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)}{2} = \begin{bmatrix} -0.7 \\ -0.7 \end{bmatrix} klf$$

(uplift pressure resultant for the toe of the foundation)

$$(x_{UL})_{toe} := TWIDTH - \frac{TWIDTH \cdot \left(\left(2 \cdot (\sigma_{UL})_{max.toe}\right) + (\sigma_{UL})_{min}\right)}{3 \cdot \left((\sigma_{UL})_{max.toe} + (\sigma_{UL})_{min}\right)} = \begin{bmatrix} 1.5 \\ 1.5 \end{bmatrix} ft$$

(distance from the connection of the toe to the resultant of the uplift pressure)

Load Combinations

Resisting Side Forces - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \left(D + EV_r + Hs_r + SP_{toe} + UL_{toe}\right) = \begin{bmatrix} -1.6 \\ -1.5 \end{bmatrix} klf$$

(load case 1 for infrequent flooding)

$$\Sigma F_{toe} := \max\left(\overrightarrow{|LC1|}\right) = 1.6\ klf$$

(maximum of the drained vs undrained cases)

Factored Shear on Toe at Face of Stem

$$(V_u)_{toe} := \Sigma F_{toe} = 1.6\ klf$$

(maximum factored shear in toe)

Resultant Moment - on Toe

$$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(D \cdot (x_D)_{toe}\right) + \left(\overrightarrow{Hs_r \cdot (x_{Hs})_r}\right) \\ + \left(\overrightarrow{EV_r \cdot (x_{EV})_r}\right) + \left(\overrightarrow{SP_{toe} \cdot (x_{SP})_{toe}}\right) \\ + \left(\overrightarrow{UL_{toe} \cdot (x_{UL})_{toe}}\right) \end{pmatrix} = \begin{bmatrix} -2.7 \\ -2.5 \end{bmatrix} \frac{kip \cdot ft}{ft}$$

(load case 1 for infrequent flooding)

Maximum Factored Moment in Toe at Face of Stem

$$Mu_{toe} := \max(LC1) \cdot 1\ ft = -2.5\ kip \cdot ft$$

(resultant moment at base of floodwall stem per foot of wall)

$$Mu_{toe} := -Mu_{toe}$$

Toe Reinforcement

Bottom Bars - Main Steel

$(d_b)_{toe.bot} := \boxed{\text{Bar Size: \#8}} = 1\ in$ *(bottom bar size in toe)*

$s_{toe.bot} := 12\ in$ *(bottom bar spacing in toe)*

$c_{toe.bot} := \boxed{4''\ \text{cover}}$ *(cover for bottom reinforcement in toe)*

$(A_s)_{toe.bot} := \dfrac{0.25 \cdot \pi \cdot (d_b)_{toe.bot}^{\ 2} \cdot b}{s_{toe.bot}} = 0.785\ in^2$ *(area of steel for bottom reinforcement in toe)*

$d_{toe.bot} := TTOE - c_{toe.bot} - \left(0.5 \cdot (d_b)_{toe.bot}\right) = 13.5\ in$ *(depth to reinforcement bottom reinforcement in toe)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{toe.bot} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\dfrac{0.05 \cdot \langle f'_c - 4000\ psi \rangle}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{toe.bot} := \dfrac{(A_s)_{toe.bot} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{toe.bot}} = 0.9\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1, EM 1110-2-2104 Eq B-50)*

$(\phi M_n)_{toe.bot} := \phi_b \cdot (A_s)_{toe.bot} \cdot (F_y)_{60} \cdot \left(d_{toe.bot} - \dfrac{a_{toe.bot}}{2}\right) = 46.1\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{toe} := Check\left(Mu_{toe}, (\phi M_n)_{toe.bot}\right) = [\text{"OK"} \quad 0.06]$ *(nominal flexural check)*

Minimum Required Steel for Flexure

Solve Constraints Values

$As_{req} := 1.5\ in^2$

$Mu_{toe} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{stem.vert} - \dfrac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{stem.vert}}\right)$

$(As_{req})_{toe} := \text{find}\left(As_{req}\right) = 0\ in^2$ *(minimum required reinforcement for flexural strength)*

Minimum Required Steel per ACI

$(A_{s.min})_a := \dfrac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.543\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$(A_{s.min})_b := \dfrac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{toe.bot} = 0.5\ in^2$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$(A_{s.min})_{temp} := 0.5 \cdot 0.003 \cdot (TTOE \cdot b) = 0.324\ in^2$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$ *(minimum area of steel required for flexural capacity)*

$A_{s.min} = 0.543\ in^2$

$A_{s\_1.3} := (As_{req})_{toe} \cdot \frac{4}{3} = 0.1\ in^2$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$(A_s)_{toe.req} := \text{if } A_{s\_1.3} < (A_s)_{toe.bot} \ \| \ as \leftarrow (As_{req})_{toe} \ \text{else} \ \| \ as \leftarrow A_{s.min} = 0.039\ in^2$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$(A_s)_{toe.bot} = 0.8\ in^2$ *(area of steel provided in the horizontal direction for the toe)*

$(Steel\_Check_{bot})_{toe} := Check\left((A_s)_{toe.req}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0]$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Reinforcement

$(A_{s.min})_{temp} = 0.3\ in^2$

$(Steel\_Check_{bot.ts})_{toe} := Check\left((A_{s.min})_{temp}, (A_s)_{toe.bot}\right) = [\text{"OK"} \quad 0.4]$

(check stem reinforcement to required t&s reinforcement)

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{max} = 0.0078$ *(maximum reinforcement ratio for concrete section)*

$\rho_{actual} := \frac{(A_s)_{toe.bot}}{\left(b \cdot d_{toe.bot}\right)} = 0.0048$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{Vert})_{toe} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.6]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

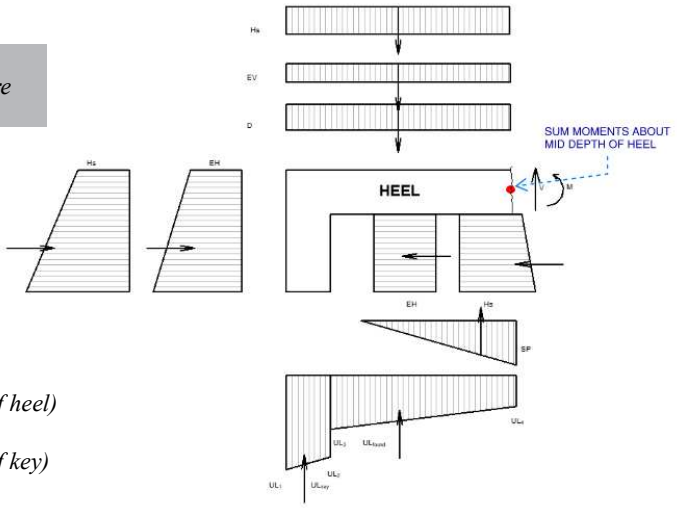
Toe - Top Lateral Reinforcement

Reference below calculations for the top steel for the heel design, top steel from heel carried through toe of base

HEEL DESIGN

Loads to Heel

Note: largest loading from drained and undrained cases used to create conservative design for loading. In each loading condition, drained loads are listed first and undrained last



$HWIDTH := BWIDTH - TTS - TWIDTH = 3.5\ ft$

(Length of heel, includes key)

Dead Load

$(\sigma_D)_{Heel} := \gamma_{conc} \cdot (TTOE) = 225\ psf$

$(\sigma_D)_{Key} := \gamma_{conc} \cdot (HK) = 150\ psf$

$D_{Heel} := (\sigma_D)_{Heel} \cdot HWIDTH = 0.8\ klf$ *(resultant dead load of heel)*

$D_{Key} := (\sigma_D)_{Key} \cdot TK = 0.2\ klf$ *(resultant dead load of key)*

$D := D_{Heel} + D_{Key} = 0.9\ klf$ *(resultant dead load of heel including key per linear foot of wall)*

$(x_{D.heel})_{heel} := \frac{HWIDTH}{2} = 1.8\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_{D.key})_{heel} := HWIDTH - \left(\frac{TK}{2}\right) = 3\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation)*

$(x_D)_{heel} := \frac{D_{Heel} \cdot (x_{D.heel})_{heel} + D_{Key} \cdot (x_{D.key})_{heel}}{D_{Heel} + D_{Key}} = 2\ ft$ *(moment arm of the dead loading from the connection of the heel to the foundation including the key)*

Hydrostatic Loads - Top of Heel

Note: hydrostatic loads applied in three directions, notated as ah = above heel, fh = face of heel and bh = behind heel

$(\sigma_{Hs})_{ah} := \gamma_{water} \cdot HTS = 0.25\ ksf$ *(vertical water pressure from hydrostatic loading)*

$(Hs)_{ah} := (\sigma_{Hs})_{ah} \cdot HWIDTH = 0.9\ klf$ *(vertical water loading from hydrostatic loading)*

$(x_{Hs})_{ah} := \frac{HWIDTH}{2} = 1.75\ ft$ *(moment arm for vertical hydrostatic loading)*

Hydrostatic Loads - Face of Heel

$(\sigma_{Hs})_{fh.top} := \gamma_{water} \cdot HTS = 0.25\ ksf$ *(min horizontal hydrostatic loading, top of foundation)*

$(\sigma_{Hs})_{fh.bot} := \gamma_{water} \cdot (HTS + THEEL) = 0.406\ ksf$ *(min horizontal hydrostatic loading, bot of key)*

$THEEL = 2.5\ ft$ *(depth of applied loading)*

$(Hs)_{fh} := \frac{THEEL \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{2} = 0.8\ klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{fh.bot} + (\sigma_{Hs})_{fh.top}\right)}\right) = 2.1\ ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Hydrostatic Loads - Back of Heel

$(\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.357 \\ 0.388 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.366 \\ 0.399 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 1\ ft$ *(depth of key from the back side face)*

$(Hs)_{bh} := \frac{HK \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{2} = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of heel)*

$(x_{Hs})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}{3 \cdot \left((\sigma_{Hs})_{bh.bot} + (\sigma_{Hs})_{bh.top}\right)}\right) = \begin{bmatrix} 1.3 \\ 1.3 \end{bmatrix} ft$ *(moment arm for the hydrostatic loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Face of Heel

$(\sigma_{EH})_{fh.top} := \gamma'_{soil} \cdot k_0 \cdot HSD = 0.047\ ksf$ *(min horizontal soil loading, top of foundation)*

$(\sigma_{EH})_{fh.bot} := \gamma'_{soil} \cdot k_0 \cdot (HSD + THEEL) = 0.124\ ksf$ *(min horizontal soil loading, top of foundation)*

Note: conservatively the lateral earth pressure does not include the undrained case where the lateral soil pressure would be zero.

$THEEL = 2.5\ ft$ *(depth of applied loading)*

$(EH)_{fh} := \frac{THEEL \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{2} = 0.2\ klf$ *(resultant of the soil loading to the front face of heel)*

$(x_{EH})_{fh} := \frac{TTOE}{2} + \left(\frac{THEEL \cdot \left(2 \cdot (\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}{3 \cdot \left((\sigma_{EH})_{fh.bot} + (\sigma_{EH})_{fh.top}\right)}\right) = 2.186\ ft$ *(moment arm for the soil loading to the front face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Lateral Earth Pressures - Back of Heel

$(\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.02 \\ 0.75 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bh.bot} = \begin{bmatrix} 1.02 \\ 0.75 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 1\ ft$ *(depth of key from the back side face)*

$(EH)_{bh} := \frac{HK \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{2} = \begin{bmatrix} 1 \\ 0.8 \end{bmatrix} klf$ *(resultant of the horizontal soil loading to the back face of heel)*

$(x_{EH})_{bh} := \frac{TTOE}{2} + \left(\frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}{3 \cdot \left((\sigma_{EH})_{bh.bot} + (\sigma_{EH})_{bh.top}\right)}\right) = \begin{bmatrix} 1.3 \\ 1.3 \end{bmatrix} ft$ *(moment arm for the soil loading to the back face of the heel; NOTE: negative value here indicates that resultant is below the base of the foundation)*

Vertical Earth Pressures - Top of Heel

$(\sigma_{EV})_{ah} := \gamma'_{soil} \cdot HSD = 0.089\ ksf$ *(vertical buoyant soil pressure on heel)*

$(EV)_{ah} := (\sigma_{EV})_{ah} \cdot HWIDTH = 0.31\ klf$ *(vertical buoyant soil loading on heel)*

$(x_{EV})_{ah} := \frac{HWIDTH}{2} = 1.75\ ft$ *(moment arm for vertical soil loading)*

Soil Pressure Loading - Base of Heel

$L_0 := BWIDTH - BIC = \begin{bmatrix} 0.83 \\ 1.97 \end{bmatrix} ft$ *(length of base with no soil pressure loading, measured from front face of key back toward toe)*

$L := HWIDTH - L_0 = \begin{bmatrix} 2.67 \\ 1.53 \end{bmatrix} ft$ *(length of base with soil pressure loading, measured from beginning of pressure back toward connection)*

$\frac{BIC}{(\sigma_{SP})_{max}} = \frac{L}{(\sigma_{SP})_{heel}}$ *(similar triangles relationship between the total soil pressure load and the length of the base in compression to the length of the heel in compression to the maximum soil pressure loading at the connection)*

$(\sigma_{SP})_{heel} := \overrightarrow{-L \cdot \frac{(\sigma_{SP})_{max}}{BIC}} = \begin{bmatrix} 0.24 \\ 0.16 \end{bmatrix} ksf$ *(maximum soil pressure loading at the connection of the heel)*

$SP_{heel} := \overrightarrow{0.5 \cdot (\sigma_{SP})_{heel} \cdot L} = \begin{bmatrix} 0.32 \\ 0.12 \end{bmatrix} klf$ *(resultant soil pressure loading on the heel)*

$(x_{SP})_{heel} := \frac{1}{3} L = \begin{bmatrix} 0.9 \\ 0.5 \end{bmatrix} ft$ *(moment arm for the soil pressure loading, measured from the connection of the heel)*

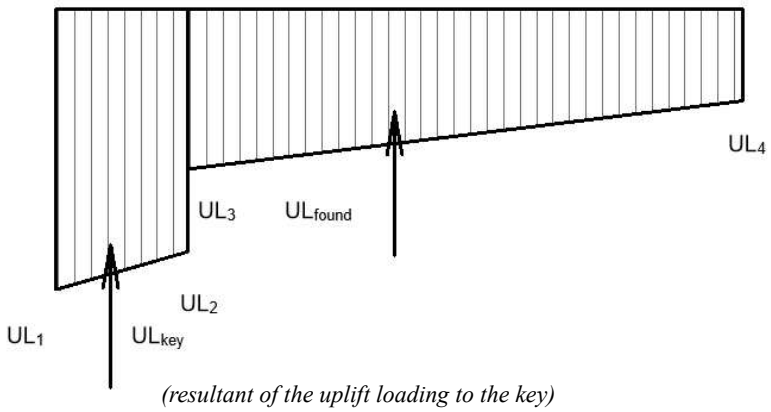
Uplifting Pressure

$UL_1 := \begin{bmatrix} 1.049 \\ 1.217 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_2 := \begin{bmatrix} 1.009 \\ 1.165 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_3 := \begin{bmatrix} 0.722 \\ 0.856 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*

$UL_4 := \begin{bmatrix} 0.406 \\ 0.44 \end{bmatrix} ksf$ *(uplift pressure, from CT Wall output)*



$UL_{key} := \frac{TK \cdot (UL_1 + UL_2)}{2} = \begin{bmatrix} 1 \\ 1.2 \end{bmatrix} klf$ *(resultant of the uplift loading to the key)*

$Heel\_Width := HWIDTH - TK = 2.5\ ft$ *(length of the heel; from the connection of the stem to the back face of the key)*

$(x_{UL})_{key} := Heel\_Width + \left(\frac{TK \cdot (2 \cdot UL_1 + UL_2)}{3 \cdot (UL_1 + UL_2)} \right) = \begin{bmatrix} 3 \\ 3 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

$m := \frac{(UL_4 - UL_3)}{BWIDTH - TK} = \begin{bmatrix} -0.0451 \\ -0.0594 \end{bmatrix} \frac{ksf}{ft}$ *(linear relationship between the uplift pressure from the foundation behind the key)*

$UL_{stem} := m \cdot (HWIDTH - TK) + UL_3 = \begin{bmatrix} 0.6 \\ 0.7 \end{bmatrix} ksf$ *(uplift pressure at the stem)*

$UL_{found} := \frac{Heel\_Width \cdot (UL_3 + UL_{stem})}{2} = \begin{bmatrix} 1.7 \\ 2 \end{bmatrix} klf$ *(resultant of the uplift loading to the foundation; less the key)*

$(x_{UL})_{found} := \left(\frac{Heel\_Width \cdot (2 \cdot UL_3 + UL_{stem})}{3 \cdot (UL_3 + UL_{stem})} \right) = \begin{bmatrix} 1.29 \\ 1.29 \end{bmatrix} ft$ *(moment arm for the uplift force on the key)*

Load Combinations

Note: Forces that are oriented to the left and up are considered negative forces and moments that would rotate the heel counterclockwise are positive for the purpose of summing forces and moments.

Forces on Heel - Horizontal Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} ((EH)_{fh} - (EH)_{bh}) \\ + ((Hs)_{fh} - (Hs)_{bh}) \end{pmatrix} = \begin{bmatrix} -0.6 \\ -0.2 \end{bmatrix} klf$ *(Summation of the forces in the horizontal direction note positive forces represent heel in compression)*

$(\Sigma F_{heelc})_{horz} := \max(LC1) = -0.2\ klf$

$(\Sigma F_{heel})_{horz} := \max(\overrightarrow{|LC1|}) = 0.6\ klf$ *(maximum of the drained vs undrained cases)*

$P\_Check :=$ if $(\Sigma F_{heelc})_{horz} > 0$
"Heel is in compression, conservatively ignore axial loads in moment capcacity check"
else
"Heel in tension, factored into moment capcacity check"

$P\_Check =$ "Heel in tension, factored into moment capcacity check"

$(\Sigma F_{heel})_{Tension} :=$ if $(\Sigma F_{heel})_{horz} > 0$
$0\ kip$
else
$|(\Sigma F_{heel})_{horz}| \cdot b$
$= 0\ kip$

Forces on Heel - Vertical Forces

$LC1 := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} D + (EV)_{ah} + (Hs)_{ah} \\ + \left(UL_{key} + UL_{found}\right) + \left(SP_{heel}\right) \end{pmatrix} = \begin{bmatrix} 8.2 \\ 8.6 \end{bmatrix} klf$ *(summation of the forces in the vertical direction)*

$(\Sigma F_{heel})_{vert} := \max\left(LC1\right) = 8.6\ klf$ *(maximum of the drained vs undrained cases)*

Resultant Shear at Base

$Vu_{heel} := (\Sigma F_{heel})_{vert} = 8.6\ klf$ *(factored shear at connection of floodwall heel)*

Resultant Axial Load in Base

$(P_u)_{heel} := (\Sigma F_{heel})_{horz} = 0.6\ klf$ *(factored axial load at floodwall heel)*

$(\Sigma F_{heel})_{Tension} = 0\ ft \cdot klf$ *(tension in heel; from check above, zero if heel in compression)*

Note: Axial loads with positive values put the heel of the floodwall in compression and negative values put the heel of the floodwall in tension.

Resultant Moment - on Heel at Stem Face

$LC1_{pos} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{D \cdot (x_D)_{heel}}\right) \\ + \left(\overrightarrow{(EV)_{ah} \cdot (x_{EV})_{ah}}\right) + \left(\overrightarrow{(Hs)_{ah} \cdot (x_{Hs})_{ah}}\right) \\ + \left(\overrightarrow{(EH)_{fh} \cdot (x_{EH})_{fh}}\right) + \left(\overrightarrow{(Hs)_{fh} \cdot (x_{Hs})_{fh}}\right) \end{pmatrix} = 9.7\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{neg} := (\gamma_p)_{Serve.n} \cdot \begin{pmatrix} \left(\overrightarrow{(Hs)_{bh} \cdot (x_{Hs})_{bh}}\right) \\ + \left(\overrightarrow{(EH)_{bh} \cdot (x_{EH})_{bh}}\right) \\ + \left(\overrightarrow{SP_{heel} \cdot (x_{SP})_{heel}}\right) \\ + \left(\overrightarrow{UL_{key} \cdot (x_{UL})_{key}}\right) \\ + \left(\overrightarrow{UL_{found} \cdot (x_{UL})_{found}}\right) \end{pmatrix} = \begin{bmatrix} 11.6 \\ 12.2 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$\Sigma LC := \max\left(LC1_{pos} - LC1_{neg}\right) = -1.85\ kip$

$Mu_{heel} := \max\left(LC1_{pos} - LC1_{neg}\right) \cdot b = -1.8\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

Note: since section is under tension and flexure, heel to be designed per section B-4 of EM 1110-2-2104.

Heel Reinforcement

$Mu_{heel} = -1.8\ kip \cdot ft$ *(maximum factored moment at base of floodwall stem on the heel)*

$(P_u)_{heel} = 0.6\ \frac{kip}{ft}$ *(maximum factored axial tension at base of floodwall stem on the heel)*

$Vu_{heel} = 8.6\ \frac{kip}{ft}$ *(maximum factored shear at base of floodwall stem on the heel)*

Top Bars - Main Steel

$(Steel\_Check_{Lat})_{heel} := Check\left(A_{s.req}, (A_s)_{heel.lat}\right) = [\text{"OK"} \quad 0.4]$ *(check heel reinforcement to required reinforcement)*

Maximum Tensile Reinforcement, Minimum Spacing

$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$ *(reinforcement ratio from EM 1110-2-2104)*

$\rho_{actual} := \frac{(A_s)_{heel.lat}}{\left(b \cdot d_{heel.top}\right)} = 0.0051$ *(actual reinforcement ratio for concrete section)*

$(\rho\_check_{lat})_{heel} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{"OK"} \quad 0.7]$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Heel - Top Reinforcement

$(d_b)_{heel.top} = 1\ in$ *bars located at* $s_{heel.top} = 12\ in$ *centers*

Heel - Lateral Reinforcement

$(d_b)_{heel.lat} = 0.75\ in$ *bars located at* $s_{heel.lat} = 12\ in$ *centers*

Heel - Bottom Reinforcement

Reference above calculations for the bottom steel from the toe design, toe steel is transferred through the base into the heel.

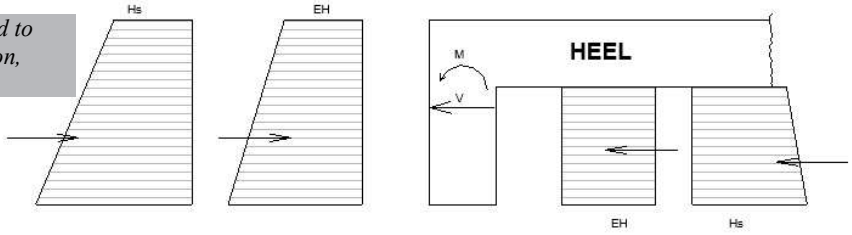
Heel - Bottom Lateral Reinforcement

Reference above calculations for the bottom steel from the toe design, toe steel is transferred through the base into the heel.

KEY DESIGN

Loads to Key

Note: Drained and undrained loading cases are checked to determine the controlling case. In each loading condition, drained loads are listed first and undrained last



$HK = 1\ ft$ *(depth of key, from bottom of foundation down)*

$THEEL = 2.5\ ft$ *(depth of key, from top of foundation down)*

Hydrostatic Loads - Front of Key

Note: hydrostatic loads applied in two directions, notated as fk = front of key and bk = back of key

$(\sigma_{Hs})_{fk1} := \gamma_{water} \cdot (HTS + TTOE) = 0.343\ ksf$ *(horizontal water loading, top of key)*

$(\sigma_{Hs})_{fk2} := \gamma_{water} \cdot (HTS + THEEL) = 0.406\ ksf$ *(horizontal water loading, bottom of key)*

$(Hs)_{fk} := \frac{HK \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})}{2} = 0.4\ klf$ *(hydrostatic loading to the front of key)*

$(x_{Hs})_{fk} := \frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{fk2}) + (\sigma_{Hs})_{fk1})}{3 \cdot ((\sigma_{Hs})_{fk2} + (\sigma_{Hs})_{fk1})} = 0.51\ ft$ *(moment arm for hydrostatic loading, measured down from key connection to foundation)*

Hydrostatic Loads - Back of key

$(\sigma_{Hs})_{bk.top} := (\sigma_{Hs})_{bh.top} = \begin{bmatrix} 0.357 \\ 0.388 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of foundation)*

$(\sigma_{Hs})_{bk.bot} := (\sigma_{Hs})_{bh.bot} = \begin{bmatrix} 0.366 \\ 0.399 \end{bmatrix} ksf$ *(hydrostatic loading to back of key, bot of key)*

$HK = 1\ ft$ *(depth of key from the back side face)*

$(Hs)_{bk} := \frac{HK \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{2} = \begin{bmatrix} 0.4 \\ 0.4 \end{bmatrix} klf$ *(resultant of the hydrostatic loading to the front face of the key)*

$(x_{Hs})_{bk} := \left(\frac{HK \cdot ((2 \cdot (\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})}{3 \cdot ((\sigma_{Hs})_{bk.bot} + (\sigma_{Hs})_{bk.top})} \right) = \begin{bmatrix} 0.5 \\ 0.5 \end{bmatrix} ft$ *(moment arm of the hydrostatic loading to the front face of the key, measured down from the connection to foundation)*

Lateral Earth Pressures - Face of Key

$(\sigma_{EH})_{fk.top} := \gamma'_{soil} \cdot k_0 \cdot (HTS + TTOE) = 0.168\ ksf$ *(min horizontal lateral earth loading, top of foundation)*

$(\sigma_{EH})_{fk.bot} := \gamma'_{soil} \cdot k_0 \cdot (HTS + THEEL) = 0.199\ ksf$ *(min horizontal lateral earth loading, bottom of foundation)*

$THEEL = 2.5\ ft$ *(depth of applied loading)*

$(EH)_{fk} := \frac{HK \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{2} = 0.2\ klf$ *(resultant of the lateral earth loading to the front face of key)*

$(x_{EH})_{fk} := \frac{HK \cdot (2 \cdot (\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})}{3 \cdot ((\sigma_{EH})_{fk.bot} + (\sigma_{EH})_{fk.top})} = 0.514\ ft$ *(moment arm of the lateral earth loading to to the front face of the key, measured from the the connection of the key to the foundation)*

Lateral Earth Pressures - Back of Key

$(\sigma_{EH})_{bk.top} := (\sigma_{EH})_{bh.top} = \begin{bmatrix} 1.02 \\ 0.754 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of foundation)*

$(\sigma_{EH})_{bk.bot} := (\sigma_{EH})_{bh.bot} = \begin{bmatrix} 1.02 \\ 0.754 \end{bmatrix} ksf$ *(lateral earth loading to back of key, bot of key)*

$HK = 1\ ft$ *(depth of key from the back side face)*

$(EH)_{bk} := \frac{HK \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{2} = \begin{bmatrix} 1 \\ 0.8 \end{bmatrix} klf$ *(resultant of the lateral earth loading to the back face of key)*

$(x_{EH})_{bk} := \frac{HK \cdot \left(2 \cdot (\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)}{3 \cdot \left((\sigma_{EH})_{bk.bot} + (\sigma_{EH})_{bk.top}\right)} = \begin{bmatrix} 0.5 \\ 0.5 \end{bmatrix} ft$ *(moment arm for the lateral earth loading to the back face of the key, measured from the connection of the key to the foundation)*

Resultant Moment - on Toe

$LC1_{fk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{fk} \cdot (x_{EH})_{fk}}\right) + \left(\overrightarrow{(Hs)_{fk} \cdot (x_{Hs})_{fk}}\right)\right) = 0.5\ \frac{kip \cdot ft}{ft}$ *(load case for positive bending moments applied to heel)*

$LC1_{bk} := (\gamma_p)_{Serve.n} \cdot \left(\left(\overrightarrow{(EH)_{bk} \cdot (x_{EH})_{bk}}\right) + \left(\overrightarrow{(Hs)_{bk} \cdot (x_{Hs})_{bk}}\right)\right) = \begin{bmatrix} 1.1 \\ 0.9 \end{bmatrix} \frac{kip \cdot ft}{ft}$ *(load case for negative bending moments applied to heel)*

Resultant Moment at Base

$LC1_{key} := LC1_{bk} - LC1_{fk} = \begin{bmatrix} 0.6 \\ 0.5 \end{bmatrix} \frac{kip \cdot ft}{ft}$

$Mu_{key} := \max\left(LC1_{bk} - LC1_{fk}\right) \cdot 1\ ft = 0.6\ kip \cdot ft$ *(factored maximum moment at connection of floodwall key to the heel)*

Key Reinforcement

Back Bars - Main Steel

$(d_b)_{key.main} :=$ Bar Size: #8 $= 1\ in$ *(main bar size in key)*

$s_{key.main} := 12\ in$ *(main bar spacing in key)*

$c_{key.main} :=$ 4″ cover *(cover for main reinforcement in key)*

$(A_s)_{key.main} := \frac{0.25 \cdot \pi \cdot (d_b)_{key.main}^{\ 2} \cdot 12\ in}{s_{key.main}} = 0.785\ in^2$ *(area of steel for top reinforcement in key)*

$d_{key.main} := TTOE - c_{key.main} - 0.5 \cdot (d_b)_{key.main} = 13.5\ in$ *(depth to main reinforcement in key)*

$a \cdot 0.85 \cdot f'c \cdot d = (A_s)_{key.main} \cdot f_y$ *(concrete equilibrium, ACI 318-19, section 22.2)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot \left(f'_c - 4000\ psi\right)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.8$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

$a_{key.main} := \frac{(A_s)_{key.main} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{key.main}} = 0.9\ in$ *(depth of equivalent stress block, ACI 318-19 Eq. 22.2.2.4.1)*

$(\phi M_n)_{key.main} := \phi_b \cdot (A_s)_{key.main} \cdot (F_y)_{60} \cdot \left(d_{key.main} - \frac{a_{key.main}}{2}\right) = 46.1\ kip \cdot ft$ *(nominal flexural strength, ACI 318-19)*

$(Flex_{nom})_{key} := Check\left(Mu_{key}, (\phi M_n)_{key.main}\right) = [\text{“OK”} \quad 0.01]$ *(nominal flexural check, utilization ratio)*

Minimum Required Steel for Flexure

Solve Constraints Values

$$As_{req} := 1.5\ in^2$$

$$Mu_{key} = \phi_b \cdot As_{req} \cdot (F_y)_{60} \cdot \left(d_{key.main} - \frac{As_{req} \cdot (F_y)_{60}}{0.85 \cdot f'_c \cdot d_{key.main}}\right)$$

$$As_{req.stem} := \mathbf{find}\left(As_{req}\right) = 0.011\ in^2$$

$$(A_{s.min})_{key.min} := As_{req.stem} = 0\ in^2$$

Minimum Required Steel per ACI

$$(A_{s.min})_a := \frac{3 \cdot \sqrt{f'_c \cdot psi}}{(F_y)_{60}} \cdot b \cdot d_{key.main} = 0.5\ in^2$$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(a))*

$$(A_{s.min})_b := \frac{200\ psi}{(F_y)_{60}} \cdot b \cdot d_{key.main} = 0.5\ in^2$$ *(minimum area of steel required ACI 318-19, Section 9.6.1.2(b))*

Minimum Requirements for Reinforcement

$$(A_{s.min})_{temp} := 0.003 \cdot \left(\frac{TK \cdot b}{2}\right) = 0.216\ in^2$$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

Note: Per ACI 318-19Section 9.6.1.3, if the area of steel provided is 1.333 times the area of steel required by analysis than 9.6.1.1 and 9.6.1.2 of ACI need not apply

$$A_{s.min} := \max\left((A_{s.min})_a, (A_{s.min})_b\right)$$ *(minimum area of steel required for flexural capacity)*

$$A_{s.min} = 0.543\ in^2$$

$$A_{s\_1.3} := (A_{s.min})_{key.min} \cdot \frac{4}{3} = 0\ in^2$$ *(1/3 greater than steel required, ACI 318-19, Section 9.6.1.3)*

$$(A_s)_{key.req} := \begin{array}{l} \text{if } A_{s\_1.3} < (A_s)_{key.main} \\ \quad as \leftarrow (A_{s.min})_{key.min} \\ \text{else} \\ \quad as \leftarrow A_{s.min} \end{array} = 0.011\ in^2$$ *(required steel to meet steel requirements)*

(includes ACI 318-19 9.6.1.2(a) and (b))

(excludes ACI 318-19 9.6.1.2(a) and (b))

$$(A_s)_{key.main} = 0.8\ in^2$$ *(area of steel provided in the horizontal direction for the heel)*

$$(Steel\_Check_{Top})_{key} := Check\left((A_s)_{key.req}, (A_s)_{key.main}\right) = [\text{“OK”} \quad 0.01]$$ *(check stem reinforcement to required reinforcement)*

Temperature and Shrinkage Requirements

$$(A_{s.min})_{temp} = 0.2\ in^2$$ *(minimum temperature and shrinkage steel, EM 1110-2-2104, Section 2-9(a))*

$$(Steel\_Check_{Top.ts})_{key} := Check\left((A_{s.min})_{temp}, (A_s)_{key.main}\right) = [\text{“OK”} \quad 0.3]$$

(temperature and shrinkage steel of key, check utilization ratio)

Maximum Tensile Reinforcement, Minimum Spacing

$$\rho_{max} := 0.25 \cdot \left(\frac{0.85 \cdot \beta_1 \cdot f'_c}{(F_y)_{60}}\right) \cdot \left(\frac{87000}{87000 + \left((F_y)_{60} \cdot psi^{-1}\right)}\right) = 0.008$$ *(reinforcement ratio from EM 1110-2-2104)*

$$\rho_{actual} := \frac{(A_s)_{key.main}}{\left(b \cdot d_{key.main}\right)} = 0.0048$$ *(actual reinforcement ratio for concrete section)*

$$(\rho\_check_{main})_{key} := Check\left(\rho_{actual}, \rho_{max}\right) = [\text{“OK”} \quad 0.6]$$ *(check that actual reinforcement ratios are lower than the maximum reinforcement ratio)*

Lateral Bars

$(d_b)_{key.lat} := \text{Bar Size: \#6} = 0.75\ in$ *(lateral bar size in key)*

$s_{key.lat} := 12\ in$ *(lateral bar spacing in key)*

PROPERTIES OF I WALLS

I-Wall Dimensions

$b := 1\ ft$ *(unit width of I-wall)*

$Elev_{top} := 940\ ft$ *(top elevation of I-wall)*

$Elev_{watersurf} := 938.5\ ft$ *(elevation of water surface profile) -* ***why is this not top of wall?***

$Elev_{ground} := 931.5\ ft$ *(elevation of ground level at I-wall)*

$Elev_{bottom} := 921.5\ ft$ *(elevation of bottom of I-wall)*

$height := Elev_{watersurf} - Elev_{ground} = 7\ ft$ *(height of wall section -* ***only use this for calc of hydrostatic loading above ground - LKP)***

MATERIAL PROPERTIES

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\phi_{undrained} := 0\ deg$ *(internal friction angle of in undrained/quick analysis. Assume 0 (most conservative) according to section 6.7.6.5 of EM 1110-2-2502). Also given in DDR section 6.7.3*

$\gamma_{soil.sat} := 120\ pcf$ *(unit weight of soil, saturated -* ***was orig. 125 pcf, but DDR gives 120 pcf -LKP)***

$\gamma_{soil} := 115\ pcf$ *(unit weight of soil on site)*

$\gamma'_{soil} := \gamma_{soil.sat} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$\sigma'_n := 150\ psf$ *(effective stress normal to the wall)*

$(\delta'/\phi')_{drained} := 0.5$ *(interface friction angle ratio, EM 1110-2-2502 Table 6.2)*

$q_n := 2000\ psi$ *(assumed bearing pressure)*

$C_{A\_undrained} := 1000\ psf$ *(Cohesion)*

$k_{a\_undrained} := \tan\left(45\ deg - \frac{\phi_{undrained}}{2}\right)^2 = 1$ *Active earth pressure coefficient. As discussed above, reigning EM and DDR say to assume phi = 0, resulting in K_a of 1*

Drained Soil Conditions

$\phi_{frict\_soil\_drained} := 28\ deg$ *(internal fiction angle in the drained condition)*

$S_{A\_drained} := 100\ psf$ *(soil drained shear strength)*

$C_{A\_drained} := 0\ psf$ *(cohesion for drained conditions, EM 1110-2-2502)*

$k_{o\_drained} := 1 - \sin\left(\phi_{frict\_soil\_drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

$k_{p\_drained} := \tan\left(45\ deg + \frac{\phi_{frict\_soil\_drained}}{2}\right)^2 = 2.8$ *(passive soil pressure coefficient, resisting side, EM 1110-2-2100 eq. 3, section 5-3)*

$k_{a\_drained} := \tan\left(45\ deg - \frac{\phi_{frict\_soil\_drained}}{2}\right)^2 = 0.36$ *(active earth pressure coefficient, Rankine's Theory, also seen in section 5-3, EM 1110-2-2100)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(Youngs modulus of elasticity for steel)*

$(F_y)_{35} := 35\ ksi$ *(yield strength for 35 ksi steels, EM 1110-2-2104, Table 3-3)*

$(F_y)_{36} := 36\ ksi$ *(yield strength for 36 ksi steels)*

$(F_y)_{42} := 42\ ksi$ *(yield strength for 42 ksi steels)*

$(F_y)_{48} := 48\ ksi$ *(yield strength for 48 ksi steels)*

$(F_y)_{50} := 50\ ksi$ *(yield strength for 50 ksi steels)*

$(F_y)_{60} := 60\ ksi$ *(yield strength for 60 ksi steels)*

Concrete Properties

$b := 12\ in$ *(unit length of floodwall)*

$cover := 4\ in$ *(assumed cover to reinforcing steel)*

$f'_c := 4.5\ ksi$ *(assumed concrete compressive strength for all hydraulic structures)*

$\lambda_c := 1.0$ *(concrete modification factor)*

$\varepsilon_{ty} := 0.004$ *(yield strain in reinforcing steel)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

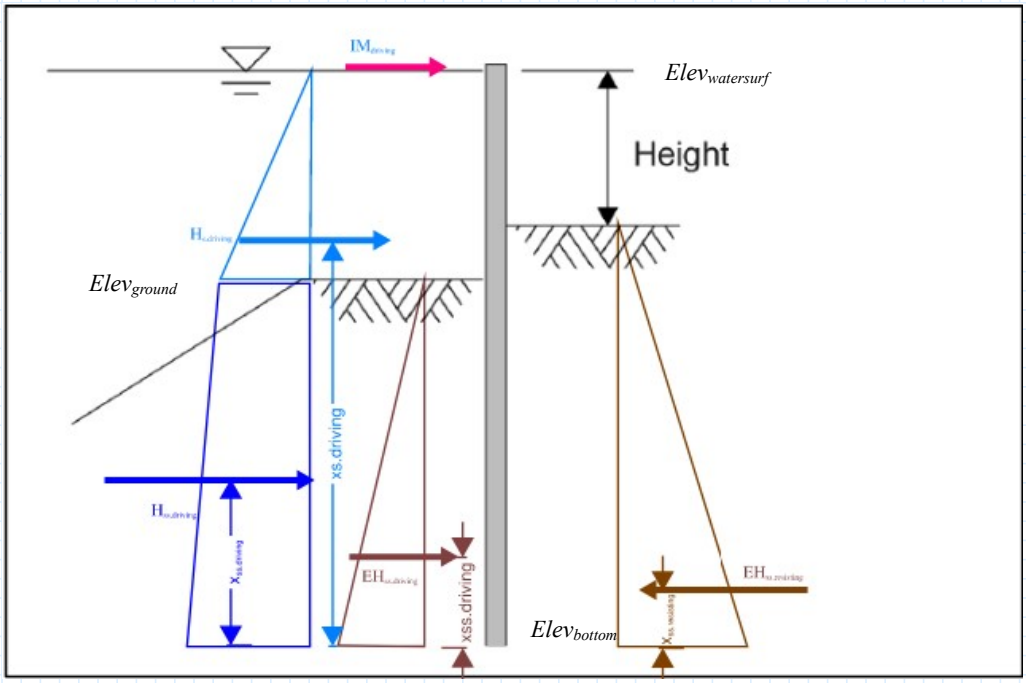
$\gamma_{concrete} := 150\ pcf$ *(unit weight of concrete)*

$f'_c := 4.5\ ksi$ *(concrete compressive strength)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength)*

$E_c := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$

LOADING CONDITIONS



Driving Side

$$P_{Hs1driving} := \frac{1}{2} \cdot \gamma_{water} \cdot \left(Elev_{watersurf} - Elev_{ground}\right) = 218.4\ psf$$

Driving side hydrostatic pressure above ground

$$P_{Hs2driving} := \frac{1}{2} \cdot \gamma_{water} \cdot \left(\left(Elev_{watersurf} - Elev_{ground}\right) + \left(Elev_{watersurf} - Elev_{bottom}\right)\right) = 748.8\ psf$$

$$F_{Htotal} := \gamma_{pile.N} \cdot \frac{1}{2} \cdot \gamma_{water} \cdot \left(Elev_{watersurf} - Elev_{bottom}\right)^2 = 12623.5\ plf$$

Driving side hydrostatic pressure below ground. Multiplied by load factor of 1.4 as given above.

$$F_{Sdriving} := \gamma_{pile.N} \cdot \frac{1}{2} \cdot \gamma'_{soil} \cdot k_{a\_undrained} \cdot \left(Elev_{ground} - Elev_{bottom}\right)^2 = 4032\ plf$$

Driving side soil force (active, soil moves away from this side. depends on degree of wall movement, assume max. 1.5" deflection). Multiplied by load factor of 1.4 as given above.
This is the item that needs work. EM 1110-2-2502 has a different equation to use if the soil is cohesive with no friction angle. But, when I use it, the value turns negative (saying that cohesion is large enough that no lateral pressures are created).

$$F_{Sresisting} := \frac{1}{2} \cdot \gamma_{soil} \cdot k_{p\_drained} \cdot \left(Elev_{ground} - Elev_{bottom}\right)^2 = 15926.5\ plf$$

Resisting side soil force (passive, soil moves towards this side) ***unrealistic, do not use - LKP***

$$F_{Sresisting} := \gamma_{pile.N} \cdot \frac{1}{2} \cdot \gamma_{soil} \cdot k_{o\_drained} \cdot \left(Elev_{ground} - Elev_{bottom}\right)^2 = 4270.8\ plf$$

Resisting side soil force (at-rest conditions)

Forces

$$F := P \cdot A$$

General equation for force caused by pressure

$$F_{Hs1driving} := P_{Hs1driving} \cdot height = 1528.8\ plf$$

Resultant hydrostatic force per linear foot of wall (good because we want per unit width)

$$F_{Hs2driving} := P_{Hs2driving} \cdot \left(Elev_{ground} - Elev_{bottom}\right) = 7488\ plf$$

Because we have an assumed horizontal deflection of 1.5", the structure has been classified as experiencing movement. Thus, active and passive earth pressures have developed.

plf is fine because we assume unit width of 1. just convert to pounds

$$F_{driving\_total} := F_{Htotal} + F_{Sdriving} = 16655.5\ plf$$

driving is lower than resisting which is not good or correct

$$F_{resisting\_total} := F_{Sresisting} = 4270.8\ plf$$

maybe we assume at rest conditions? that would make the analysis make more sense. Total angle of movement in maximum loading conditions is .018 radians, and EM 1110-2-2100 says that for passive conditions to develop, structure rotation of .02 - .2 radians required. "however, the rotation required to develop one-half the passive pressure is significantly less, as little as .005 radians"

does that mean i use half the passive pressure? or do i assume at-rest conditions???

*total horizontal force against wall = water over WHOLE length. water pressure does not change even with soil introduction. 1/2*gamma*H^2. PLUSSSSS soil force with BUOYANT gamma. buoyant gamma subtracts water from the calculation ALREADY.*

Sum the moments at the top of the wall

$d_H := \frac{2}{3} \cdot (Elev_{watersurf} - Elev_{bottom}) = 11.3\ ft$ *Point of application of hydrostatic force*

$M_H := F_{Htotal} \cdot 1\ ft \cdot d_H = 143066.6\ lbf \cdot ft$ *Moment created by hydrostatic force*

$d_S := \left((Elev_{watersurf} - Elev_{ground}) + \frac{2}{3} (Elev_{ground} - Elev_{bottom}) \right) = 13.7\ ft$ *Point of application of soil force* ***- does this differ for driving and resisting side?***

$M_S := F_{Sdriving} \cdot 1\ ft \cdot \left((Elev_{watersurf} - Elev_{ground}) + \frac{2}{3} (Elev_{ground} - Elev_{bottom}) \right) = 55104\ lbf \cdot ft$ *Moment created by soil force*

Use deflection to calculate required I

$\delta := \frac{F \cdot b^2}{6\ EI} (3\ l - b)$ *Equation for maximum deflection (at free end) in cantilevered beam, AISC*

$I := 184.20\ \frac{in^4}{ft}$ *Moment of Inertia of sheet piling per NUCOR table*

$b_h := (Elev_{watersurf} - Elev_{bottom} - d_H) = 5.7\ ft$ *B is distance of the load to the fixed end* ***- go over this with john -LKP***

$b_s := (Elev_{watersurf} - Elev_{bottom} - d_S) = 3.3\ ft$

$E_{sheet} := 48.5\ \frac{in^3}{ft}$ *Elastic modulus of sheet pile per NUCOR table* ***im confused, why is this not in a unit of force/ area ????? ksi, psi, etc.***

$\delta_H := \frac{F_{Htotal} \cdot (b_h)^2}{6\ E_{steel} \cdot I} (3\ (Elev_{top} - Elev_{bottom}) - b_h) = 1.089\ in$ *do I use E_{steel}, $E_{concrete}$, or E_{sheet}? Do i separate the deflections?*

$\delta_{S\_driving} := \frac{F_{Sdriving} \cdot (b_s)^2}{6\ E_{steel} \cdot I} (3\ (Elev_{top} - Elev_{bottom}) - b_s) = 0.126\ in$

$\delta_{S\_resisting} := \frac{F_{Sresisting} \cdot (b_s)^2}{6\ E_{steel} \cdot I} (3\ (Elev_{top} - Elev_{bottom}) - b_s) = 0.133\ in$

$\delta_{Total} := \delta_H + \delta_{S\_driving} - \delta_{S\_resisting} = 1.082\ in$ *PZ 27 is the smallest sheet pile size that does not exceed maximum deflection of 1.5"*

Inlet and Outlet Structures

Upper Turkey Creek

Merriam, KS

ASSUMPTIONS AND REFERENCES

- References used:
  1. EM 1110-2-2104 [2025] Strength Design for Reinforced Concrete Hydraulic Structures
  2. ACI 318-19
  3. EM 1110-2-2100 [2005] Stability Analysis for Concrete Structures
  4. EM 1110-2- 2502 [2022] Floodwall and Other Hydraulic Retaining Walls
- Load factors are denoted by γ values and strength reduction factors are denoted by ϕ values
- Extreme loading cases are not required for outfall structures. Floodwall system and project defined as retaining the loading from the 100 year [1% AEP event]. Per EM 1110-2-2104 Section 3-2 d. Strength Design per EM 1110-2-2104 and ACI 318-19, Stability per EM 1110-2-2100 and assumed to be "Normal" for sliding.
- Assumed two general load conditions; 1) saturated soil to top of wall with no free water, and 2) free water to 1/2 of the height (varied along the wingwall) with the inside empty.
- Earthquake loading is ignored as the loading period for the floodwalls exceeds the loading for earthquake frequencies. Construction loads are also negated as equipment will not be allowed to pass over the outlet or inlet structures during typical construction practices.
- The design for the outlet structures will also apply to the inlet structures, design governed by the outlet structures as they are taller.

$(Elev_f$

Landside Hydrostatic Loading (Resisting Side)

Note: the hydrostatic loading for the back face of the stem wall is isolated to the hydrostatic pressure in the soils above the pipe connection to the back face, as well as the assumed hydrostatic pressure inside of the pipe connected to the outlet structure stem. Hydrostatic pressure assumed to be the ground surface elevation as this conservatively assumes that the ground behind the wall is saturated; conservatively the higher of the elevations is taken between the flood event elevation or the ground surface elevation at the floodwall.

10 Year Event Elevation

$$(Elev_f)_{10.RS} := \left\| \begin{array}{l} \text{for } i \in \text{ORIGIN} .. 19 \\ \quad \left\| (Elev_f)_{10.RS_i} \leftarrow \max\left((Elev_f)_{10_i}, (Elev_{Land})_{Wall_i}\right) \right. \\ \text{return } (Elev_f)_{10.RS} \end{array} \right.$$

(maximum elevation for the water surface elevation on the resisting side, take as higher of the grand surface elevation or the water elevation for the 10 year flood)

100 Year Event Elevation

$$(Elev_f)_{100.RS} := \left\| \begin{array}{l} \text{for } i \in \text{ORIGIN} .. 19 \\ \quad \left\| (Elev_f)_{100.RS_i} \leftarrow \max\left((Elev_f)_{100_i}, (Elev_{Land})_{Wall_i}\right) \right. \\ \text{return } (Elev_f)_{100.RS} \end{array} \right.$$

(maximum elevation for the water surface elevation on the resisting side, take as higher of the grand surface elevation or the water elevation for the 100 year flood)

Riverside Hydrostatic Loading (Resisting Side)

$$(Hs_{10})_{ToW.RS} := \gamma_{water} \cdot \left((Elev_f)_{10.RS} - ToW \cdot ft\right) = \begin{bmatrix} 3.4 \\ 2.4 \\ 4.7 \\ 4.9 \\ \vdots \end{bmatrix} psi$$

(hydrostatic pressure at the top of the outfall wall in the 10 year flood on the river side)

$$(Hs_{10})_{slab.RS} := \gamma_{water} \cdot \left((Elev_f)_{10.RS} - \left(ToW \cdot ft - E_{outfall}\right)\right) = \begin{bmatrix} 5.6 \\ 4.6 \\ 7.6 \\ 7.1 \\ \vdots \end{bmatrix} psi$$

(hydrostatic pressure at the top face of the slab of outfall structure in the 10 year flood on the rivers side)

$(Hs_{100})_{ToW.RS} := \gamma_{water} \cdot \langle (Elev_f)_{100.RS} - ToW \cdot ft \rangle = \begin{bmatrix} 4.5 \\ 3.9 \\ 7 \\ 7.2 \\ \vdots \end{bmatrix} psi$ *(hydrostatic pressure at the top of the outfall wall in the 100 year flood on the river side)*

$(Hs_{100})_{slab.RS} := \gamma_{water} \cdot \langle (Elev_f)_{100.RS} - \langle ToW \cdot ft - E_{outfall} \rangle \rangle = \begin{bmatrix} 6.7 \\ 6.1 \\ 9.8 \\ 9.3 \\ \vdots \end{bmatrix} psi$ *(hydrostatic pressure at the top face of the slab of outfall structure in the 100 year flood on the rivers side)*

Resultant Hydrostatic Pressure

Lateral Earth Pressures

Note: Lateral earth pressures are calculated assuming that the soil behind the outfall structure will be saturated. Lateral earth pressures are accounting for the soil not present in the area of the pipe, but neglects any bedding material and conservatively assumes lateral earth pressure around the pipe, applied to the

Shear Strength

Drained Conditions

$(\tau_f)_{drained} := \sigma'_n \cdot \tan\left((\delta'/\phi')_{drained} \cdot \phi_{frict\_soil\_drained}\right) = 0\ psi$ *(shear stress on wall at failure, EM 1110-2-2502 Eq 6.6)*

Undrained Conditions

$(\tau_f)_{undrained} := (c_a/s_u)_{undrained} \cdot (s_u)_{undrained} = 0.4\ psi$ *(limiting shear stress on the wall at failure, EM 1110-2-2502, EQ 6.7)*

Active Earth Pressures

$\phi'_d := \phi_{frict\_soil\_drained} = 26\ deg$ *(developed friction angle, drained conditions, EM 1110-2-2502, Eq 6.19)*

$(\delta'/\phi')_{drained} = 0.5$ *(interface friction angle ratio, EM 1110-2-2502 Table 6.2)*

$\delta'_d := (\delta'/\phi')_{drained} \cdot \phi'_d = 13\ deg$ *(developed interface friction coefficient, EM 1110-2-2502, Eq 6.19)*

$$(K_A)_{coeff} := \frac{\left(\cos\left(\phi'_d - \Theta\right)\right)^2}{\left(\cos\left(\Theta\right)^2 \cdot \cos\left(\delta'_d + \Theta\right)\right) \cdot \left(1 + \sqrt{\frac{\sin\left(\phi'_d + \delta'_d\right) \cdot \sin\left(\phi'_d - \beta_{RS}\right)}{\cos\left(\delta'_d + \Theta\right) \cdot \cos\left(\Theta - \beta_{RS}\right)}}\right)^2}$$

(active earth pressure accounting for the developed angle of wall friction, wall angle and sloping soil, EM 1110-2-2502, Eq 6.19)

$(K_A)_{DS} := (K_A)_{coeff} \cdot (K_A)_{DS}$ *(active earth pressure accounting for slope angles, EM 1110-2-2502, Eq 6.19)*

Passive Earth Pressures

$$(K_P)_{coeff} := \frac{\left(\cos\left(\phi'_d + \Theta\right)\right)^2}{\left(\cos\left(\Theta\right)^2 \cdot \cos\left(\delta'_d - \Theta\right)\right) \cdot \left(1 - \sqrt{\frac{\sin\left(\phi'_d + \delta'_d\right) \cdot \sin\left(\phi'_d + \beta_{RS}\right)}{\cos\left(\delta'_d - \Theta\right) \cdot \cos\left(\Theta - \beta_{RS}\right)}}\right)^2}$$

(passive earth pressure accounting for the developed angle of wall friction, wall angle and sloping soil, EM 1110-2-2502, Eq 6.20)

Area of Loading for Horizontal Earth Pressure

$A_{Stem} := \overrightarrow{\left(P_{outfall} \cdot E_{outfall}\right)} - \left(0.25 \cdot \overrightarrow{\pi \cdot \left((P_{pipe.in})_{outfall}\right)^2}\right)$ *(cross sectional area of the stem wall minus the pipe)*

$A_{Key} := \overrightarrow{\left(G_{outfall} \cdot B_{outfall}\right)}$ *(cross sectional area of the key, or front face of slab)*

Lateral Earth Pressure Locations

Note: its assumed that the pipe comes out of the outfall stem at mid-height of the stem wall and thus the centroid location of the loading is half of the wall height. Conservatively, the lateral earth pressure is assumed to be at the 1/3 height location

$(y_{bar})_{Stem} := \frac{E_{outfall}}{3}$ *(centroid location of the horizontal loading to the stem wall)*

$$(y_{bar})_{Key} := \frac{-G_{outfall}}{2}$$

(centroid location of the horizontal loading to the key, from the top face of the slab)

Lateral Earth Pressures

Undrained Quick (Q-case)

$$(p_{a.ud})_{stem} := (\gamma_{soil} \cdot E_{outfall}) + (\gamma_{water} \cdot E_{outfall}) - \left(2 \cdot (s_u)_{undrained} \cdot \sqrt{1 + (c_a/s_u)_{undrained}}\right)$$

(undrained active pressure behind stem wall, EM 1110-2-2502, Eq 6.22)

$$(p_{a.ud})_{key} := (\gamma_{soil} \cdot G_{outfall}) + (\gamma_{water} \cdot ((Elev_f)_{100.RS} - ToW \cdot ft + E_{outfall})) - \left(2 \cdot (s_u)_{undrained} \cdot \sqrt{1 + (c_a/s_u)_{undrained}}\right)$$

(undrained active pressure behind key wall, EM 1110-2-2502, Eq 6.22)

$$(p_{p.ud})_{stem} := (\gamma_{soil} \cdot E_{outfall}) + (\gamma_{water} \cdot ((Elev_f)_{100.RS} - ToW \cdot ft + E_{outfall})) + \left(2 \cdot (s_u)_{undrained} \cdot \sqrt{1 + (c_a/s_u)_{undrained}}\right)$$

(undrained passive pressure behind stem wall, EM 1110-2-2502, Eq 6.24)

$$(p_{p.ud})_{key} := (\gamma_{soil} \cdot G_{outfall}) + (\gamma_{water} \cdot ((Elev_f)_{100.RS} - ToW \cdot ft + E_{outfall})) + \left(2 \cdot (s_u)_{undrained} \cdot \sqrt{1 + (c_a/s_u)_{undrained}}\right)$$

(undrained passive pressure behind key wall, EM 1110-2-2502, Eq 6.24)

Drained Quick (S-case)

$$(p'_{a.d})_{stem} := \overrightarrow{(\gamma'_{soil} \cdot E_{outfall} \cdot (K_A)_{DS})}$$

(drained active pressure behind stem wall, EM 1110-2-2502, Eq 6.12, Note that second term is zero)

$$(p'_{a.d})_{key} := \overrightarrow{(\gamma'_{soil} \cdot G_{outfall} \cdot (K_A)_{DS})}$$

(drained active pressure behind key wall, EM 1110-2-2502, Eq 6.12, Note that second term is zero)

$$(p'_{p.d})_{stem} := \overrightarrow{(\gamma'_{soil} \cdot E_{outfall} \cdot (K_p)_{RS})}$$

(drained active pressure behind stem wall, EM 1110-2-2502, Eq 6.12, Note that second term is zero)

$$(p'_{p.d})_{key} := \overrightarrow{(\gamma'_{soil} \cdot G_{outfall} \cdot (K_p)_{RS})}$$

(drained active pressure behind key wall, EM 1110-2-2502, Eq 6.12, Note that second term is zero)

Note: Stirrups are not required to support longitudinal bars in stem wall. Wingwall bars will provide lateral containment.

U.S.ARMY CORPS OF ENGINEERS - KANSAS CITY DISTRICT

Triple Box Culvert Headwall at Quaker Creek

Upper Turkey Creek

MERRIAM, KS

ASSUMPTIONS

- Serviceability Loading conditions and single-load factors per EM 1110-2-2104, ASCE 7-16 where EM 2104 is silent
- Reference 'UTC Floodwall Justification Calcs' for justification on using service level single load factor analysis in lieu of multi-factored strength design for T-wall sections
- Assumption that the tallest wall section with the largest hydraulic loading will govern design, all other shorter sections of wall stem will have smaller loading, thus are ok.
- Both Drained and Undrained loading cases are used for analysis, for each of the sections of wall the largest of the loading cases is taken to produce the most conservative loading analysis.

MATERIAL PROPERTIES AND LOAD FACTORS

Soil and Water Properties

$\gamma_{water} := 62.4\ pcf$ *(unit weight of water)*

$\gamma_{soil} := 120\ pcf$ *(unit weight of saturated soil)*

$\gamma'_{soil} := \gamma_{soil} - \gamma_{water} = 57.6\ pcf$ *(buoyant unit weight of soil)*

$q_n := 2000\ psi$ *(bearing pressure, Reference DDR Table 9.2)*

Drained Soil Conditions

$\phi_{drained} := 28\ deg$ *(internal friction angle for drained soil condition)*

$C_{drained} := 0\ psf$ *(cohesion for drained soil condition)*

$k_0 := 1 - \sin\left(\phi_{drained}\right) = 0.531$ *(at-rest soil pressure coefficient for the drained condition)*

Steel Properties

$\gamma_{steel} := 490\ pcf$ *(unit weight of steel)*

$E_{steel} := 29000\ ksi$ *(young's modulus of elasticity for steel)*

$(F_y)_{30} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$(F_y)_{60} := 60\ ksi$ *(yield strength of 60 ksi steel)*

$\varepsilon_{ty} := \frac{(F_y)_{60}}{E_{steel}} = 0.0021$ *(yield strain of 60 ksi steel)*

Concrete Properties

$f'_c := 4500\ psi$ *(concrete compressive strength for all structures)*

$f'c := f'_c \cdot psi^{-1}$ *(unitless concrete compressive strength for all structures)*

$\lambda := 1.0$ *(concrete modification factor)*

$cover_3 := 3\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$cover_4 := 4\ in$ *(concrete cover for reinforcement; EM 1110-2-2104, Table 2-1)*

$\gamma_{conc} := 150\ pcf$ *(concrete unit weight)*

$Ec := 57000 \cdot \sqrt{f'c} \cdot psi = 3823.7\ ksi$ *(young's modulus of elasticity for concrete)*

$n := \frac{E_{steel}}{Ec} = 7.6$ *(transformed section ratio)*

$\varepsilon_c := 0.003$ *(yield strain in concrete in compression)*

$\beta_1 := \begin{cases} 0.65 & \text{if } f'_c \geq 8000\ psi \\ 0.85 - \left(\frac{0.05 \cdot (f'_c - 4000\ psi)}{1000\ psi}\right) & \text{else if } f'_c > 4000\ psi \\ 0.85 & \text{else} \end{cases} = 0.825$ *(beta value from ACI 318-19, Table 22.2.2.4.3)*

Load Factors

Serviceability Load Factors

Note: the unusual loading condition is used for the top of the floodwalls since they are designed to the 100 year event. the usual loading condition is defined as the 10 year event.

$(\gamma_p)_{Serve.u} := 2.2$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-1)*

$(\gamma_p)_{Serve.n} := 1.6$ *(serviceability load factor for permanent loading, EM 1110-2-2104, Table 3-1)*

Strength Limit States

$\phi_b := 0.9$ *(bending load reduction factor - ACI 318-19 21.2.2, Table 21.2.2)*

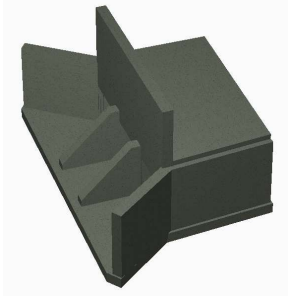
$\phi_A := 0.9$

$\phi_V := 0.75$ *(shear load reduction factor - ACI 318-19 Table 21.2.1)*

$\phi_C := 0.65$ *(compression load reduction factor - ACI 318-19 Table 21.2.2)*

$\phi_T := 0.9$ *(tension load reduction factor - ACI 318-19 Table 21.2.2)*

BOX DIMENSIONS



Headwall

$(Elev_{wall})_{top} := 920.25\ ft$ *(elevation at top of wall)*

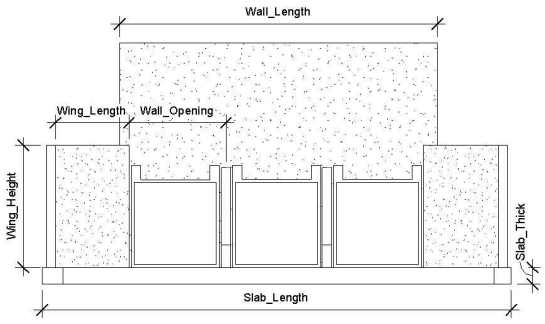
$(Elev_{wall})_{bot} := 900.25\ ft$ *(elevation at bottom of wall)*

$Wall_{height} := (Elev_{wall})_{top} - (Elev_{wall})_{bot}$ *(height of stem wall)*

$Wall_{height} = 20\ ft$

$Wall_{thick} := 18\ in$ *(thickness of wall)*

$Wall_{length} := 28.37\ ft$ *(length of monolith)*



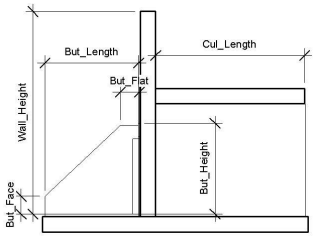
Wingwall

$Wing_{thick} := 18\ in$ *(thickness of wingwall)*

$Wing_{height} := 11\ ft$ *(total height of wingwall, from top of slab)*

$Wing_{length} := 11.5\ ft$ *(length of the wingwall)*

Buttress Wall



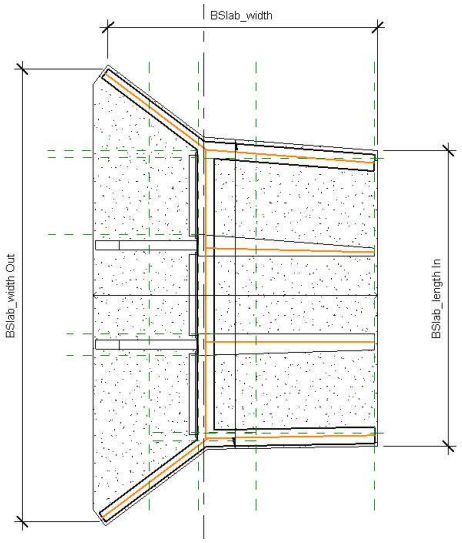
$Buttress_{thick} := 18\ in$ *(thickness of buttress wall)*

$Buttress_{height.front} := 1.5\ ft$ *(height of buttress wall at front face)*

$Buttress_{height.back} := 8.9\ ft$ *(height of buttress wall at back face)*

$Buttress_{length} := 9.33\ ft$ *(length of the wingwall)*

Culvert Walls



$CWall_{thick} := 18\ in$ *(wall thickness)*

$CWall_{height} := 7\ ft$ *(wall height)*

$CWall_{length} := 15\ ft$ *(wall length)*

Top Slab

$TSlab_{thick} := 18\ in$ *(slab thickness)*

$TSlab_{width} := Wall_{length} = 28.4\ ft$ *(wall width)*

$TSlab_{length} := CWall_{length} = 15\ ft$ *(wall length)*

Bottom Slab

$BSlab_{thick} := 18\ in$ *(slab thickness)*

$BSlab_{width} := 24.5\ ft$ *(slab width)*

$BSlab_{length.in} := 26.85\ ft$ *(slab length, measured at the back of the slab)*

$BSlab_{length.out} := 41.25\ ft$ *(slab length, measured at the front of the slab)*

LOADS

Permanent Loads

Dead Loads

Note: dead loads are calculated as the force per unit length of the member per foot of depth of the member.

$D_{stem} := \gamma_{conc} \cdot (Wall_{thick} \cdot 1\ ft) = 225\ plf$ *(self weight of concrete, per foot of depth per foot of wall length)*

$D_{wing} := \gamma_{conc} \cdot (Wing_{thick} \cdot 1\ ft) = 225\ plf$ *(self weight of concrete, per foot of depth per foot of wall length)*

$D_{but} := \gamma_{conc} \cdot (Buttress_{thick} \cdot 1\ ft) = 225\ plf$ *(self weight of concrete, per foot of depth per foot of buttress length, conservatively uses the width at bottom of wall)*

$D_{cwall} := \gamma_{conc} \cdot (CWall_{thick} \cdot 1\ ft) = 225\ plf$ *(self weight of concrete, per foot of depth per foot of wall length)*

Vertical Earth Loads

$Elev_{soil} := 912\ ft$ *(soil elevation at resisting side, on top of box)*

$Elev_{box.top} := (Elev_{wall})_{bot} + CWall_{height} + TSlab_{thick} = 908.8\ ft$ *(elevation of the box top)*

$d_{soil} := Elev_{soil} - Elev_{box.top} = 3.2\ ft$ *(soil cover at resisting side of box)*

$\sigma_{EV} := \gamma_{soil} \cdot d_{soil} = 0.39\ ksf$ *(vertical soil pressure at the top slab of box)*

Lateral Earth Loads to Back of Stem Wall

$d_{soil} = 3.2\ ft$ *(soil cover at resisting side of box)*

$k_0 = 0.5$ *(at-rest lateral earth pressure coefficient)*

$\sigma_{EH.r} := k_0 \cdot \gamma_{soil} \cdot d_{soil} = 0.207\ ksf$ *(maximum lateral earth pressure of soil on resisting side)*

Lateral Earth Loads to Wingwalls

$(d_{soil})_{wingwall} := CWall_{height} + d_{soil} + TSlab_{thick} = 11.7\ ft$ *(depth of soil on the wingwall)*

$k_0 = 0.5$ *(at-rest lateral earth pressure coefficient)*

$\sigma_{EH.wing} := k_0 \cdot \gamma_{soil} \cdot (d_{soil})_{wingwall} = 0.748\ ksf$ *(maximum lateral earth pressure of soil on wingwalls)*

Lateral Earth Loads on Exterior Box Walls

$(d_{soil})_{wall.top} := d_{soil} + TSlab_{thick} = 4.7\ ft$ *(depth of soil on the exterior walls, at top)*

$(d_{soil})_{wall.bot} := (d_{soil})_{wingwall} = 11.7\ ft$ *(depth of soil on the exterior walls, at bottom)*

$\sigma_{EH.wall.top} := k_0 \cdot \gamma_{soil} \cdot (d_{soil})_{wall.top} = 0.302\ ksf$ *(lateral soil pressure at the top of the exterior wall)*

$\sigma_{EH.wall.bot} := k_0 \cdot \gamma_{soil} \cdot (d_{soil})_{wall.bot} = 0.748\ ksf$ *(lateral soil pressure at the bottom of the exterior wall)*

Gravity Loads - Silt

Note: assume that silt is slightly more dense than the native soil, based on reduced voids from being saturated and then settling in place. Silt in loads placed on both the front face of the slab as well as the upstream end of the slab; inside the conduit of the culvert.

$\gamma_{silt} := \gamma_{soil} \cdot 1.2 = 144\ pcf$ *(unit density of silt applied to structure)*

$Silt\_in\_depth := 4\ in$ *(assumed silting depth)*

$\sigma_{Gravity} := \gamma_{silt} \cdot Silt\_in\_depth = 0.048\ ksf$ *(pressure loading to slab)*

Pavement Loading

$\gamma_{asphalt} := 145\ pcf$ *(unit density of asphalt pavement)*

$depth_{roadway} := 12\ in$ *(depth of roadway section)*

$width_{roadway} := 15\ ft$ *(width of the roadway affecting box)*

$b := 12\ in$ *(analysis width)*

$P := \gamma_{asphalt} \cdot depth_{roadway} \cdot width_{roadway} \cdot b = 2.2\ kip$ *(effective point load from pavement above box)*

$D_1 := 2 \cdot (d_{soil} \cdot 0.5) + width_{roadway} = 18.2\ ft$ *(effective loading area from roadway, AASHTO LRFD Figure 3.11.6.3-1)*

$\Delta\sigma_v := \frac{P}{D_1 \cdot b} = 0.1\ ksf$ *(effective pressure from roadway, AASHTO LRFD Figure 3.11.6.3-1)*

Note: Surcharge only applied to the top slab of the box and not applied laterally to the wall as the soil depth does not allow for the lateral surcharge force in the wall to develop. soil is at a depth of $d_{soil} = 3.2\ ft$ and the wall is approximately 10 ft from the back of the curb.

Temporary Loading

Hydrostatic Loading

$\sigma_{Hs.bot} := \gamma_{water} \cdot Wall_{height} = 1.25\ ksf$ *(unit loading to the bottom of the box wall, loading to top face of bottom slab)*

$\sigma_{Hs.top.r} := \gamma_{water} \cdot d_{soil} = 0.203\ ksf$ *(back of stem wall due to hydrostatic pressure in resisting side soil)*

$\sigma_{Hs.cond} := \gamma_{water} \cdot CWall_{height} = 0.437\ ksf$ *(hydrostatic loading to conduit and back face of stem wall due to water inside conduit)*

$\sigma_{Hs.wingwall} := \gamma_{water} \cdot Wall_{height} = 1.25\ ksf$ *(hydrostatic loading to wingwall)*

Vehicle Live Load

$LLDF := 1.15$ *(LRFD live load distribution factor, LRFD Table 3.6.1.2.6a-1)*

$s_w := 6\ ft$ *(wheel spacing, AASHTO 3.6.1.2.6b)*

$s_a := 8\ ft$ *(axel spacing, AASHTO 3.6.1.2.6b)*

$w_t := 20\ in$ *(tire patch width, AASHTO 3.6.1.2.6b)*

$l_t := 10\ in$ *(tire patch length, AASHTO 3.6.1.2.6b)*

$D_i := 7\ ft = 84\ in$ *(inside clear diameter of culvert, AASHTO 3.6.1.2.6b)*

$$H_{int} := \frac{s_w - w_t - 0.06\ D_i}{LLDF} = 3.4\ ft$$ *(load interaction depth transverse, AASHTO eq. 3.6.1.2.6b-1)*

(load interaction depth, AASHTO eq. 3.6.1.2.6b-2 and 3)

$$w_w := \begin{cases} \text{if } d_{soil} < H_{int} \\ \quad w_t + \left(LLDF \cdot d_{soil}\right) + 0.06 \cdot \left(D_i\right) \\ \text{else} \\ \quad w_t + s_w + \left(LLDF \cdot d_{soil}\right) + 0.006 \cdot \left(D_i\right) \end{cases} = 5.8\ ft$$

$$H_{int\_p} := \frac{s_a - l_t}{LLDF} = 6.2\ ft$$ *(load interaction depth, AASHTO eq. 3.6.1.2.6b-4)*

$$l_w := \begin{cases} \text{if } d_{soil} < H_{int\_p} \\ \quad l_t + LLDF \cdot d_{soil} \\ \text{else} \\ \quad l_t + s_a + LLDF \cdot d_{soil} \end{cases} = 4.6\ ft$$ *(live load patch length, AASHTO eq. 3.6.1.2.6b-5 and 6)*

$A_{LL} := l_w \cdot w_w = 26.6\ ft^2$ *(rectangular area of applied load, AASHTO eq. 3.6.1.2.6a-1)*

$D_E := d_{soil} \cdot ft^{-1} = 3.2$ *(minimum depth of earth cover above the structure, 3.6.2.2)*

$IM := \max\left(\left(33 \cdot \left(1.0 - 0.125 \cdot D_E\right)\right), 0\right) = 19.6$ *(dynamic load allowance, AASHTO eq. 3.6.2.2-1)*

$m := 1.0$ *(multiple presence factor, AASHTO table 3.6.1.1.2-1)*

$P := 32\ kip$ *(live load applied at surface, AASHTO eq. 3.6.1.2.6b-7)*

$$P_L := \frac{P \cdot \left(1 + \frac{IM}{100}\right) \cdot m}{A_{LL}} = 1.438\ ksf$$ *(applied live vehicle load at top slab surface, AASHTO eq. 3.6.1.2.6b-7)*

Dynamic Loads

Impact Loads

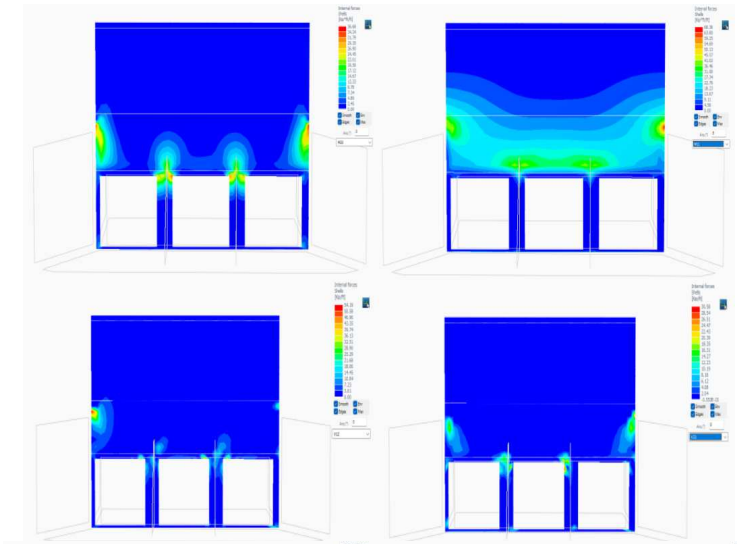
Note: Assume that impact loads are concentrated at the top 6 inches of the wall.

$IM := 0.1\ klf$ *(applied impact loading, reference DDR)*

$depth := 0.5\ ft$ *(height of applied impact loading)*

$$F_{IM} := \frac{IM}{depth} = 0.2\ ksf$$ *(impact loading in model, applied to structure)*

RAM ELEMENTS OUTPUTS



Stem Wall

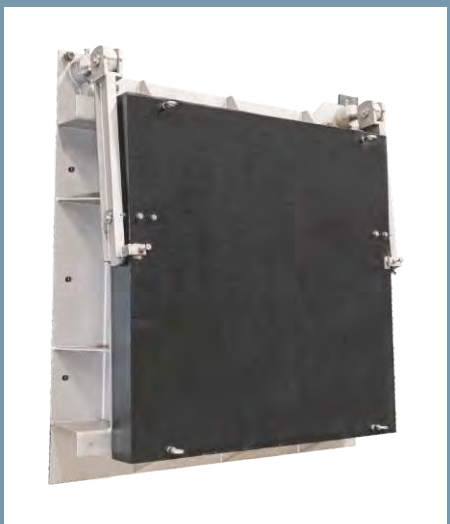
RODNEY HUNT
SINCE 1840

Rodney Hunt

Water & Sewage Control Equipment



FLAP GATES

Backflow Prevention in Free Discharge Application

THE BIGGEST CAST IRON GATES MANUFACTURERS OF THE WORLD

ENGINEERING EXCELLENCE AND EXPERIENCE

Since 1840, the engineering team at Rodney Hunt has pioneered safe and reliable flow control systems in thousands of applications around the world. In 2016, Rodney Hunt joined forces with Jash Engineering Ltd., a company with 68 years experience in manufacturing of flow control products and having a leadership position in Asia. Together, we bring more than 250 years of experience designing customized solutions to meet the needs of the most challenging applications worldwide.

COMPREHENSIVE PRODUCT OFFERING

Our product offering is unrivalled in the flow control marketplace. From all types and sizes of cast and fabricated gates, in a wide variety of material options encompassing metals and plastics, to custom valve and actuation options, we bring a total solution to every project. The breadth of our product offering enables us to bring unequaled expertise to your planning and decision making process.

SUPERIOR QUALITY

We bring exceptional quality to every project using application based solutions, proven designs, manufacturing flexibility and rigorous testing procedures. We offer one of the most flexible and comprehensive cast, metal fabrication, machining, assembly and testing operations at our in-house facilities in the USA and India. This allows us to monitor and ensure quality in all aspects of production and to provide consistent reliable and superior products.

RESPONSIVE SERVICE

We pride ourselves on providing professional responsiveness to your needs throughout the design, manufacturing and installation processes. Our engineering team is available for consultation during all phases of your project. Dedicated project managers serve as a single point of contact once the order is in-house and our knowledgeable field service team is always ready to provide on-site support.

Two 60" (1500 mm) Series 60 Flap Gates help protect a North Dakota watershed from forward and reverse surges.

FLAP GATES & FEATURES

RODNEY HUNT
SINCE 1840

BACKFLOW PREVENTION IN FREE DISCHARGE APPLICATIONS:

Rodney Hunt flap gates (or flap valves) are designed as an efficient backflow prevention solution in most free discharge application. These are often used for automatic drainage from outfall structures to rivers, estuaries and sea & for preventing reverse flow during flood / tide from rivers, estuaries and sea to the plant.

These are gravity operated and need minimal water pressure for operation. The flap opens when the head in the pipe or conduit exceeds 0.2 feet above the head in the receiving body of water. The flap closes when the head in the receiving body of water exceeds the head in the pipe or conduit. When fully open the flap gate/valve offers a very low head-loss.

Rodney Hunt offers flap gates / valves with many different options and features as shown hereunder to suit specific applications:

OPENING AND SIZE OPTIONS:

Round, square and rectangular shaped opening as per client's requirement in a wide range of sizes starting from 4 inch to 144 inch and greater.

MATERIAL OPTIONS:

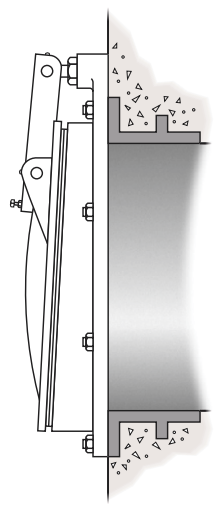
Cast Iron / Cast Ductile Iron / Alloy Cast Iron / Fabricated Stainless Steel / Aluminum, HDPE or Composite construction depending upon application, head and fluid condition.

MULTI-FLAP / DOOR OPTION:

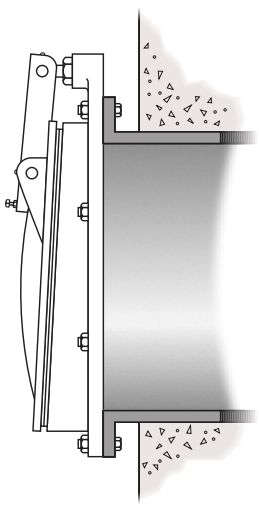
Multiple doors to cover the opening in large sized flap gates, when specified.

MOUNTING OPTIONS:

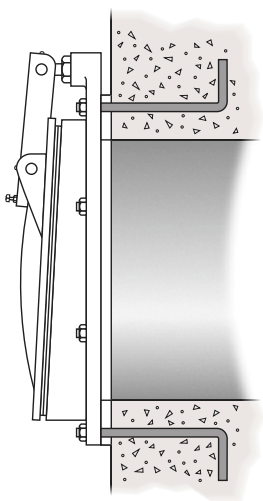
Various mounting options available such as Wall thimble mounted / Pipe flange mounted / Wall mounted as shown below.



Wall Thimble Mounted



Pipe Flange Mounted



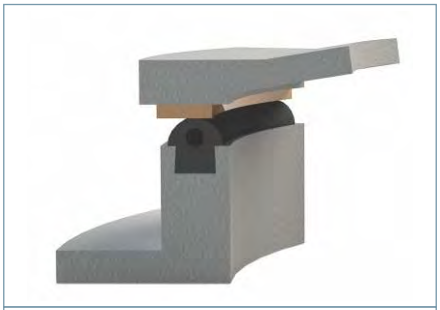
Wall Mounted

FLAP GATES & FEATURES

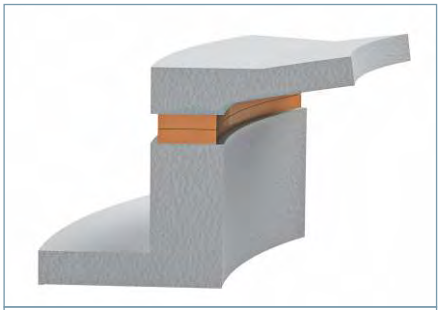
SEALING OPTIONS:

Depending upon material of construction of flap gate, varied sealing options as shown below are offered for achieving low leakage in valve closed condition.

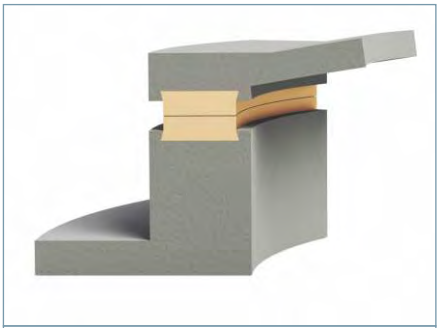
Cast Iron to Rubber for
Cast Iron Flap Gate



Bronze to Rubber for
Cast Iron Flap Gate



Metal to Metal Fitted on Plain Face
for Cast Iron Flap Gate



Metal to Metal in Dovetail Groove
for Cast Iron Flap Gate

Metal to Rubber for
Fabricated Flap Gate

HDPE to Rubber for
HDPE Flap Gate

HINGE OPTIONS:

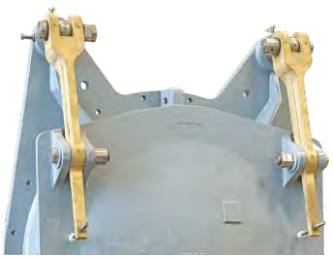
Depending upon requirement and size single or double hinged design is offered. Both single hinged or double hinged designs can be provided with double pivot to increase sensitivity.

Single Hinge Double Pivot

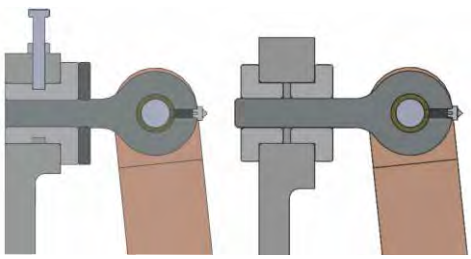
Double Hinge Double Pivot

ADJUSTABLE UPPER AND LOWER PIVOT OPTIONS:

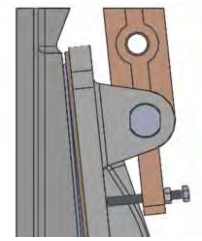
Adjustable upper pivot is provided to adjust the flap gates sensitivity to unseating head. The lower pivot is provided to allow for a controlled amount of cover rotation to ensure that cover seat and body seat lie in the same plane. Adjustable upper pivot & lower pivot are provided generally in large sized flap gates.



Adjustable Upper & Lower Pivot



Upper Pivot Options



Lower Pivot

ANTI LOCKING BAR & BUMPER SPRING OPTION:

- Anti-locking bar and bumper spring options are used in pump discharges application.
- Anti-locking bar is provided to prevent flap / cover overturn damage, when specified.
- Bumper is given in case of pump discharge application, to prevent flap from traveling over 90° and hitting the wall.

Anti Locking Bar Option

Bumper Spring Option

Rodney Hunt has the capability to design and manufacture flap gates for varied applications as requested by client and incorporate custom features to suit the application. Rodney Hunt offers the widest range of flap gates in the industry as show cased in the subsequent pages.

CAST IRON FLAP GATES

SERIES: A - 601

SINGLE HINGED - DOUBLE PIVOT

DOUBLE HINGED - DOUBLE PIVOT

SPECIFICATION:

These flap gates are made as per Rodney Hunt design.

APPLICATION:

These flap gates are suitable for back flow prevention applications and suitable for seating head up to 20 feet.

SIZE RANGE:

- From 4 inch to 30 inch.

FEATURES:

- Frame / body suitable for directly mounting on face of the wall using anchor fasteners and secondary grout between wall and frame / body or on wall thimble or on pipe flange.
- Single piece flap cover to withstand applicable head.
- Resilient seal to absorb closing shocks.
- Resilient seal mounted in machined groove on frame / body and in contact with mating face of flap cover.
- Double pivot design for all sizes of flap gate.
- Single hinge design upto flap gate size 10" & double hinge design above 10".
- Tamper proof locking arrangement for hinge pin.

OPTIONAL FEATURES:

- Wall thimble mounting.
- Mounting flange drilling pattern to match 25 lb. or 125 lb. as required.
- Mating face of flap cover provided with non corrosive seat to match resilient seal on frame / body.
- Metallic sealing arrangement comprising of non ferrous seats mounted on frame / body in contact with matching non ferrous seat mounted on flap cover.

MATERIAL OF CONSTRUCTION:

Frame / Body	Cast Iron ASTM A126 Class B
Flap Cover	Cast Iron ASTM A126 Class B
Frame / Body Seat Facing	Neoprene ASTM D-2000 or Bronze B21 – C464
Flap Cover Seat Facing	Cast Iron ASTM A126 Class B or Bronze B21 C464
Hinges	Stainless Steel 304
Fasteners	Stainless Steel 304 / 316

SHOP TESTING:

Seat clearance check of each flap gate for checking clearance between mating sealing face.

CAST IRON FLAP GATES

SERIES: A - 602 (FV - AC & FV - ACP)

DOUBLE HINGED - DOUBLE PIVOT FLAP GATE

SPECIFICATION:

These flap gates are made as per Rodney Hunt design.

APPLICATION:

These flap gates are suitable for back flow prevention applications and suitable for high seating head condition as per requirement.

SIZE RANGE:

- From 12 inch to 108 inch for FV-AC design.
- From 12 inch to 60 inch for FV-ACP design.
- Higher sizes can be offered on request.

FEATURES:

- Frame / body suitable for directly mounting on face of the wall using anchor fasteners and secondary grout between wall and frame / body or on wall thimble or on pipe flange.
- Single piece flap cover to withstand high seating head.
- Sensitive to low unseating head – opens at 0.2 feet.
- Resilient seal to absorb closing shocks.
- Resilient sealing arrangement comprising of resilient seal mounted in machined groove on frame/body and in contact with mating face of flap cover.
- Double pivot design for all sizes of flap gate.
- Adjustable upper and lower pivot to adjust sensitivity to unseating head.
- Rigidly designed hinge arms/brackets.
- Adjustable hinge bolts of toughened steel to reduce / increase sensitivity of flap cover operation.
- Replaceable hinge pins and hinge bushes.

ADDITIONAL FEATURES FOR FV-ACP DESIGN TO BE USED FOR PUMP DISCHARGE APPLICATION:

- Anti-locking bar to prevent flap overturn damage.
- Spring bumper to limit disc travel to 90 degrees.

OPTIONAL FEATURES:

- Wall thimble mounting.
- Mounting flange drilling pattern to match 25 lb. or 125 lb. as required.
- Mating face of flap cover provided with non corrosive seat to match resilient seal on frame / body.
- Metallic sealing arrangement comprising of non ferrous seats mounted on frame / body in contact with matching non ferrous seat mounted on flap cover.

MATERIAL OF CONSTRUCTION:

Frame / Body	Cast Iron ASTM A126 Class B
Flap Cover	Cast Iron ASTM A126 Class B
Frame / Body Seat Facing	Neoprene ASTM D-2000 or Bronze B21 – C464
Flap Cover Seat Facing	Neoprene ASTM D-2000 or Cast Iron ASTM A126 Class B or Bronze B21 – C464
Hinge Arm	Ductile Iron ASTM A536 65-45-12 / Bronze B98 – C655
Hinge Bolt	Toughened Steel
Anti-Locking Bar	Steel
Bumper Spring	Heat Treated Spring Steel A 689
Fasteners	Stainless Steel 304 / 316

SHOP TESTING:

Seat clearance check of each flap gate for checking clearance between mating sealing face.

DOUBLE HINGED - DOUBLE PIVOT FLAP GATE

SPECIFICATION:

These flap gates are made as per Rodney Hunt design.

APPLICATION:

These flap gates are suitable for back flow prevention applications and suitable for high seating head condition as per requirement.

SIZE RANGE:

- From 12 inch to 108 inch.
- Higher sizes can be offered on request.

FEATURES:

- Square / Rectangular flange back frame / body for directly mounting on face of wall using anchor fasteners and secondary grout between wall & frame / body or to wall thimble.
- Single piece flap cover to withstand high seating head.
- Sensitive to low unseating head – opens at 0.2 feet.
- Resilient seal to absorb closing shocks.
- Resilient sealing arrangement comprise of resilient seal mounted on frame / body and in contact with mating face of flap cover.
- Double pivot design for all sizes of flap gate.
- Adjustable upper and lower pivot to adjust sensitivity to unseating head.
- Rigidly designed hinge arms/brackets.
- Adjustable hinge bolts of toughened steel to reduce / increase sensitivity of flap cover operation.
- Replaceable hinge pins and hinge bushes.

OPTIONAL FEATURES:

- Wall thimble mounting.
- Mating face of flap cover provided with non corrosive seat to match resilient seal on frame / body.
- Metallic sealing arrangement comprising of non ferrous seats mounted on frame / body in contact with matching non ferrous seat mounted on flap cover.
- Multiple flap covers to cover the opening in large sized flap gates, when specified.

MATERIAL OF CONSTRUCTION:

Frame / Body	Cast Iron ASTM A126 Class B
Flap Cover	Cast Iron ASTM A126 Class B
Frame / Body Seat Facing	Neoprene ASTM D-2000 or Bronze B21 – C464
Flap Cover Seat Facing	Neoprene ASTM D-2000 or Cast Iron ASTM A126 Class B or Bronze B21 – C464
Hinge Arm	Bronze B98 – C655
Hinge Bolt	Toughened Steel
Fasteners	Stainless Steel 304 / 316

SHOP TESTING:

Seat clearance check of each flap gate for checking clearance between mating sealing face.

RODNEY HUNT

FABRICATED FLAP GATES

SERIES: A - 611 & A - 612

SERIES: A - 611

SERIES: A - 612

SPECIFICATION:

These flap gates are made as per Rodney Hunt design.

APPLICATION:

These flap gates are suitable for back flow prevention applications & suitable for high seating head condition as per requirement.

SIZE RANGE:

- From 12 inch to 108 inch.
- Higher sizes can be offered on request.

SERIES:

- **A-611:** Round flange back frame/body for directly mounting on face of wall using anchor fasteners and secondary grout between wall and frame/body or on the wall thimble or on the pipe flange.
- **A-612:** Square / Rectangular flange back frame / body for mounting on face of wall using anchor fasteners and secondary grout between wall and frame/body or to wall thimble.

FEATURES:

- Single piece flap cover to withstand applicable head.
- Resilient seal to absorb closing shocks.
- Resilient sealing arrangement comprise of resilient seal mounted on outer peripheral edge of frame/body and in contact with mating face of flap cover.
- Single or double pivot design depending upon size, sensitivity require per the application.
- Single hinge design upto flap gate size 10" & double hinge design above 10".
- Sizes 30" and above provided with rigidly designed hinge arms / brackets having provision for adjustment of the flap gate sensibility to unseating head.
- Replaceable hinge pins and self lubricating hinge bushings.

OPTIONAL FEATURES:

- Wall thimble mounting.
- Mounting flange drilling pattern to match 25 lb. or 125 lb. as required.
- Material can be offer in Aluminum.

MATERIAL OF CONSTRUCTION:

Frame / Body	Stainless Steel ASTM A240-304L/316L
Flap Cover	Stainless Steel ASTM A276-304L / 316L
Hinge Arm	Stainless Steel ASTM A276-304L / 316L
Seals	Neoprene ASTM D-2000
Hinge Bushing	UHMWPE ASTM D-4020
Hinge Bolt	Toughened Steel
Fasteners	Stainless Steel 304 / 316

Higher grade of stainless steel can be offered on request.

SHOP TESTING:

Seat clearance check of each flap gate for checking clearance between mating sealing face.

CWX: Concrete Wall Mounted Termination of Pipe

HDPE FLAP GATES

SERIES: A - 641 & A - 642

SERIES: A - 641

SERIES: A - 642

SPECIFICATION:

These flap gates are made as per Rodney Hunt design.

APPLICATION:

For low cost back flow prevention applications in low head conditions. HDPE material enable light weight construction thereby offering ease in installation and also high corrosion resistance, longevity and minimum maintenance.

SIZE RANGE:

- From 12 inch to 60 inch.
- Higher sizes can be offered on request.

SERIES:

- **A-641:** Round flange back frame / body for directly mounting on face of wall using anchor fasteners and secondary grout between wall and frame / body or on the wall thimble or on the pipe flange.
- **A-642:** Square / Rectangular flange back frame / body for mounting on face of wall using anchor fasteners and secondary grout between wall & frame/body or to wall thimble.

FEATURES:

- Single piece flap cover to withstand applicable head. Door may also have stainless steel stiffening depending upon size.
- Resilient seal to absorb closing shocks.
- Resilient sealing arrangement comprise of resilient seal mounted on outer peripheral edge of frame/body and in contact with mating face of flap cover.
- Single or double pivot design depending upon size, sensitivity required and application.
- Single or double hinged with hinge sized to prevent formation of oval hole due to higher applying forces.
- Replaceable hinge pins and self lubricating hinge bushings.

OPTIONAL FEATURES:

- Wall thimble mounting.
- Mounting flange drilling pattern to match 25 lb. or 125 lb. as required.
- Stainless Steel frame can be offered on request.

MATERIAL OF CONSTRUCTION:

Frame / Body	HDPE ASTM D-4020 / Stainless Steel ASTM A240-304L / 316L
Flap Cover	HDPE ASTM D-4020
Stiffners	HDPE / Stainless Steel
Hinge arm	Stainless Steel ASTM A240-304L / 316L
Seals	Neoprene ASTM D-2000
Hinge Bushing	UHMWPE ASTM D-4020
Hinge Pin & Washers	Stainless Steel 304
Fasteners	Stainless Steel 304 / 316

SHOP TESTING:

Seat clearance check of each flap gate for checking clearance between mating sealing face.

COMPOSITE FLAP GATES

SERIES: A - 652

SERIES: A - 652

SPECIFICATION:

These flap gates are made as per Rodney Hunt design.

APPLICATION:

Back flow prevention applications in low head conditions. Composite material enable high corrosion resistance, longevity and minimum maintenance.

SIZE RANGE:

- From 12 inch to 108 inch.
- Higher sizes can be offered on request.

FEATURES:

- Square / Rectangular fabricated flange back frame / body for mounting on face of wall using anchor fasteners and secondary grout between wall and frame/body or to wall thimble.
- Single piece flap cover manufactured as a composite sandwich construction comprising of light weight rigid cellular core with a fully welded steel matrix covered by rigid compressed composite plastic to withstand applicable head.
- Flap cover is internally chemical bonded, sealed and free of exposed reinforcing material.
- Resilient seal to absorb closing shocks.
- Resilient sealing arrangement comprise of resilient seal mounted on outer peripheral edge of frame / body and in contact with mating face of flap cover.
- Double pivot design for all sizes of flap gate.
- Double hinged with hinge sized to prevent formation of oval hole due to higher applying forces.
- Replaceable hinge pins and self lubricating hinge bushings.

OPTIONAL FEATURES:

- Wall thimble mounting.

MATERIAL OF CONSTRUCTION:

Frame / Body	Stainless Steel ASTM A240-304L / 316L OR FRP
Flap Cover	Composite FRP & Steel OR FRP
Hinge Arm	Stainless Steel ASTM A240-304 / 316
Seals	Neoprene ASTM D-2000
Hinge Bushing	UHMWPE ASTM D-4020
Hinge Bolt	Toughened Steel
Fasteners	Stainless Steel 304 / 316

Higher grade of stainless steel can be offered on request.

SHOP TESTING:

Seat clearance check of each flap gate for checking clearance between mating sealing face.

FLEXIBLE FLAP GATES
SERIES: A - 672

SERIES: A - 672

SPECIFICATION:

These flap gates are made as per Rodney Hunt design.

APPLICATION:

For low cost back flow prevention applications in low head conditions. A stainless steel frame with neoprene material enable light weight construction thereby offering ease in installation and also high corrosion resistance, longevity and minimum maintenance.

SIZE RANGE:

- From 12 inch to 48 inch.
- For wider openings, two or more can be bonded and clamped.

FEATURES:

- Square / Rectangular flange back frame / body for mounting on face of wall using anchor fasteners and secondary grout between wall and frame/body or to wall thimble.
- Opens under very low unseating head.
- Resilient seal to withstand slamming action of pump discharge and wave action.
- Single piece flap cover to withstand applicable head. Door may also have stainless steel stiffening depending upon size.
- Stainless steel frame with flexible reinforced neoprene flap.

OPTIONAL FEATURES:

- Wall thimble mounting.
- Neoprene to neoprene seating for low leakage.

MATERIAL OF CONSTRUCTION:

Frame / Body	Stainless Steel ASTM 240-304L / 316L
Flap Cover	Neoprene / EPDM ASTM D-2000
Stiffeners	Stainless Steel ASTM A240-304L / 316L
Fasteners	Stainless Steel 304 / 316

SHOP TESTING:

Seat clearance check of each flap gate for checking clearance between mating sealing face.

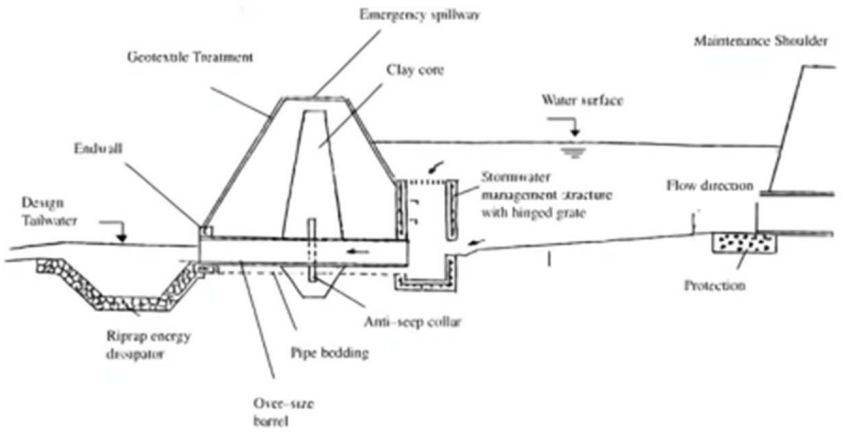
US Army Corps of Engineers

Upper Turkey Creek
Detention Pond Drop Inlet Structure
Sta. 57+60 (Approx.)

Comp by: JWW 01/29/2026
Chkd by:

Notes:
1. Inlet structure 1will drain through a 2 48" RCP with inlet at top and low flow near the bottom of the box.
2. There is a flapgate at Turkey Creek. Water is assumed to the top of structure with full hydrostatic head and at-rest soil pressures applied for loading and assumed empty for uplift.



Elevations:

$EL_1 := 897.58\ ft + 2\ in = 897.747\ ft$ — Top of structure + assumed 2" settlement per DDR

$EL_{inv} := 890\ ft$ — Invert elevation per Civil Plans

$EL_S := EL_1$ — Elev. of soil

$H_{inv} := EL_1 - EL_{inv} = 7.747\ ft$ — Top of structure to top of base slab

Dimensions:

$D := 10 \cdot in$ — Wall thickness (all walls)

$C_{c1} := 2.5 \cdot in$ — Wall clear cover

$L_{short} := 3.5 \cdot ft$ — Clear distance Short Span

$L_{long} := 12.0 \cdot ft$ — Clear distance Long Span

$D_f \equiv 12 \cdot in$ — Base slab thickness

$C_{cf} := 2.5 \cdot in$ — Base slab clear cover

$t_{tslab} := 0 \cdot in$ — Top slab thickness (No Top Slab/Grate Only):

$L_{ext} := 12 \cdot in$ — Base slab overhang (length of that extends beyond walls)

$D_{p1} := 1 \cdot ft$ — opening height entering structure

$D_{p2} := 4 \cdot ft$ RCP diameter exiting structure

$Grate := 2.67\ ft \cdot 2.67\ ft = 7.129\ ft^2$ Grate at top of structure

Design Parameters:

$F_y := 60\ ksi$ Steel Yield Strength

$f_c := 4000 \cdot psi$ Concrete Strength

$\gamma_c := 150 \cdot pcf$ Concrete Unit Weight

$\gamma_w := 62.4 \cdot pcf$ Water Unit Weight

Soil Properties:

$\gamma := 115 \cdot pcf$ Blanket Unit Weight (Assumed from DDR)

$\phi := 28 \cdot deg$ Internal Friction Angle (Assumed from DDR)

$surcharge := 0\ psf$ Surcharge - none assumed for controlling flood case, also negligible at controlling locations analyzed (just above or below top of pipe)

$HEAD := 0 \cdot ft$ Height of water in gatewell; conservatively assumed empty

$K_o := 1 - \sin(\phi) = 0.531$ At-rest soil coefficient

Strength Reduction Factors:

$\phi_V := 0.75$ Shear Strength

$\phi_B := 0.90$ Flexural Strength

Load Factors: EM 1110-2-2104, 2023 Chapter 3 (Table 3-2)

$\gamma_N := 1.4$ Unusual Load Factor 10 to 750 year return period

Load Cases:

Unusual Case (100 year return period): reference the Justification Calculations, single load case for serviceability governs design over strength cases.

Flotation Check:

Weight:

Note: The base slab extension is included for submerged soil weight only. It is ignored for uplift since water acts on top and bottom.

$W_{long\_walls1} := 1 \cdot \left(\left(H_{inv} - t_{tslab}\right) \cdot \left(L_{long} + 2 \cdot D\right) - \left(D_{p1} \cdot L_{long}\right)\right) \cdot D \cdot \gamma_c = 11.734$ **kip**

$W_{long\_walls2} := 1 \cdot \left(\left(H_{inv} - t_{tslab}\right) \cdot \left(L_{long} + 2 \cdot D\right) - \left(\frac{D_{p2}^{\,2} \cdot \pi}{4}\right)\right) \cdot D \cdot \gamma_c = 11.663$ **kip**

$W_{short\_walls} := 2 \cdot \left(\left(H_{inv} - t_{tslab}\right) \cdot \left(L_{short}\right)\right) \cdot D \cdot \gamma_c = 6.778$ **kip**

$W_{top\_slab} := \left(\left(L_{short} + 2 \cdot D\right) \cdot \left(L_{long} + 2 \cdot D\right) - Grate\right) \cdot t_{tslab} \cdot \gamma_c = 0$ **kip**

$Base_{SlabArea} := \left(L_{short} + \left(2 \cdot D\right)\right) \cdot \left(L_{long} + \left(2 \cdot D\right)\right) = 70.611$ **ft²**

$W_{base\_slab} := Base_{SlabArea} \cdot D_f \cdot \gamma_c = 10.592$ **kip**

Total Weight of Structure:

$W_S := W_{long\_walls1} + W_{short\_walls} + W_{top\_slab} + W_{base\_slab} + W_{long\_walls2}$ $W_S = 41$ **kip**

Weight of soil (submerged weight):

$soil_{area} := \left(L_{long} + 2 \cdot D + L_{ext}\right) \cdot L_{ext} \cdot 2 = 29.333$ **ft²**

$H_{soil} := H_{inv} - \left(EL_1 - EL_S\right) = 7.747$ **ft**

$W_G := soil_{area} \cdot H_{soil} \cdot \left(\gamma - \gamma_w\right) = 11.953$ **kip**

Water In Structure:

$W_C := \gamma_w \cdot HEAD \cdot \left(\left(L_{short}\right) \cdot \left(L_{long}\right)\right) = 0$ **lbf** $W_C = 0$ **kip**

Structure Factor of Safety for Flotation

$H_u := H_{inv} + D_f$ Depth to bottom of structure

Uplift under Base:

$p_u := H_u \cdot \gamma_w$ $p_u = 545.792$ **psf** Pore water pressure om structure

$Uplift := p_u \cdot Base_{SlabArea}$ $Uplift = 38.539$ **kip**

Stability of structure: **Note:** Reference EM 1110-1-2100, Table 3-4. The required factor of safety for flotation of a structure with unusual load conditions (as defined in Table 3-1) is 1.2.

$Stability := \frac{W_S + W_C + W_G}{Uplift}$ $Stability = 1.37$

$Check_{Stability} := \text{if}(Stability \geq 1.2, \text{“Okay”}, \text{“Not Okay”})$ $Check_{Stability} = \text{“Okay”}$

Strength Analysis

Strength Check #1 - 6" above pipe (full box section)

Wall Loading:

Height from invert to location of analysis: $z := 4.5 \cdot ft$

Height from top of structure to location of analysis: $H_z := H_{inv} - z = 3.247\ ft$

Unusual Case: Soil & Flood Pressures:
Top of structure head on the outside with the structure empty.

$p_u := \gamma_N \cdot (K_o \cdot (\gamma - \gamma_w) \cdot H_z + \gamma_w \cdot H_z + surcharge) = 410\ psf$

For 1 ft strip of the Wall: $b := 12 \cdot in$

$w_u := p_u \cdot b$ $w_u = 410\ plf$

Moment Demand:

Use moment distribution to determine corner moment:

Define lengths to mid-point of intersecting wall for analysis:

$L_1 := L_{long} + D = 12.833\ ft$ $L_2 := L_{short} + D = 4.333\ ft$

Moment at center of intersection of walls:

$M_{u\_center} := \frac{w_u}{12} \cdot \left(L_1^2 - (L_1^2 - L_2^2) \cdot \frac{L_2}{L_1 + L_2} \right) = 4.374\ kip \cdot ft$

Negative moment at face of long wall (note: the short wall has the largest negative moment):

$$M_{u\_neg} := M_{u\_center} - w_u \cdot \left(L_{short} + D\right) \cdot \frac{D}{4} + \frac{w_u \cdot D^2}{8} = 4.039 \ \textit{kip} \cdot \textit{ft}$$

Max Positive Moment for Long Span

$$M_{u\_pos} := \frac{w_u \cdot L_1^{\,2}}{8} - M_{u\_center} = 4.077 \ \textit{kip} \cdot \textit{ft}$$

Max moment:

$$M_u := \max\left(M_{u\_neg}, M_{u\_pos}\right) \qquad M_u = 4.08 \ \textit{kip} \cdot \textit{ft}$$

Moment Capacity:

Axial Load: $P_u := 0 \ \textit{kip}$ $b = 1 \ \textit{ft}$

Diameter of bar: $d_b := \frac{6}{8} \cdot \textit{in}$ #6's @ 12" EW/EF

Area of bar: $A_s := \frac{\pi \cdot d_b^{\,2}}{4} = 0.442 \ \textit{in}^2$

$$d := D - C_{cl} - \frac{d_b}{2} = 7.13 \ \textit{in}$$

$$a := \frac{A_s \cdot F_y + P_u}{0.85 \cdot f_c \cdot b} = 0.65 \ \textit{in}$$ EM 2104 Eq (D-2) rearranged to define "a"

$$\phi M_n := \phi_B \cdot \left(0.85 \cdot f_c \cdot a \cdot b \cdot \left(d - \frac{a}{2}\right) - P_u \cdot \left(d - \frac{D}{2}\right)\right) = 13.519 \ \textit{kip} \cdot \textit{ft}$$ EM 2104 Eq. (D-1)

$$Ratio := \frac{M_u}{\phi M_n} \qquad Ratio = 0.30$$

$$Check_{Moment} := \text{if}\left(\phi M_n > M_u, \text{“OKAY”}, \text{“NO GOOD”}\right) \qquad Check_{Moment} = \text{“OKAY”}$$

Minimum Steel Check:

Solve for minimum required for strength:

Solver Constraints Values

$$A_{sreq} := 0.1 \cdot \textit{in}^2$$

$$M_u = \phi_B \cdot \left(0.85 \cdot f_c \cdot \frac{A_{sreq} \cdot F_y + P_u}{0.85 \cdot f_c \cdot b} \cdot b \cdot \left(d - \frac{\frac{A_{sreq} \cdot F_y + P_u}{0.85 \cdot f_c \cdot b}}{2}\right) - P_u \cdot \left(d - \frac{D}{2}\right)\right)$$ EM 1110-1-2104 Eq. (D-1) with "a" defined from (D-2) substituted

$$A_{sreq} := \text{Find}\left(A_{sreq}\right) = 0.129 \ \textit{in}^2$$

Minimum per EM 2104 3.5.1.4 (2016 Ed.)

$$A_{smin'} := \max\left(\left(\frac{200 \cdot b \cdot d}{F_y} \cdot psi\right), \left(\frac{3 \cdot \sqrt{f_c \cdot psi}}{F_y} \cdot b \cdot d\right)\right) = 0.285\ in^2$$

$$A_{smin} := min\left(A_{smin'}, \left(\frac{4}{3} \cdot A_{sreq}\right)\right) = 0.17\ in^2$$

$Check_{min} := \text{if}\left(A_s > A_{smin}, \text{“OKAY”}, \text{“NO GOOD”}\right)$ $Check_{min} = \text{“OKAY”}$

Minimum Reinforcement Required for Temperature and Shrinkage:

- Appendix B – USACE Provided Drawings
- Appendix C – Evaluation Matrix
- Appendix D – Hydraulic Analysis
- Appendix E – Proposed Typical Sections
- Appendix F – Concept Exhibits
- Appendix G – Quantities

1. Executive Summary

In March 2025, the United States Army Corps of Engineers (USACE) appointed HNTB to perform an analysis of the Johnson Drive bridge over Turkey Creek to develop a conceptual design that may reduce flood risk to downtown Merriam. In the scope of work, HNTB was given the following tasks:

- Analyze Johnson Drive bridge concepts developed by USACE
- Provide insight on up to two (2) additional viable alternatives
- Estimate impacts to surrounding infrastructure
- Develop a decision matrix
- Provide a recommended alternative
- Estimate quantities for the recommended alternative
- Facilitate discussions with government, city, and HNTB to drive alternative selection

Existing conditions at the Johnson Drive crossing indicate the bridge overtops in major storm events. The existing bridge has a low chord elevation of 914.89' at the east abutment (low side) while the 1% annual exceedance probability (i.e. 100-yr event) water surface elevation is 918.62'. Because several interrelated variables impact hydraulic performance, the project was analyzed holistically. A decision matrix was developed focused on two primary perspectives: increasing the effective cross-sectional area and bridge types. The resulting recommendation is to utilize a concrete haunched slab bridge with moderately raised Johnson Drive profile and a channel widening to the west of approximately 30'.

The recommended alternative provides the following benefits compared to the other options covered later in this report:

- Minimizes impacts to surrounding properties and infrastructure (estimated 13 partially affected tracts and 3 possible total acquisitions, refer to Figure G.4).
- Does not require realignment of Johnson Drive or Merriam Drive.
- Profile changes along Johnson Drive can be tied into along Merriam Drive with minimal impacts.
- Provides opportunity to reconstruct and maintain access of the Turkey Creek Streamway Trail.
- Ability to provide a seamless connection to adjacent floodwalls by incorporating structural fascia walls, thereby providing some freeboard to the 100-yr event water surface elevation.

However, as with any alternative, there are some drawbacks:

- Channel widening to the west assumes closure of Campbell Lane. Access to a few residences, along with Merriam Christian Church, will be negatively impacted.
- Profile raise of Johnson Drive may require abandonment of the parking lot at the northeast corner of the intersection with Merriam Drive. Likewise, the BP gas station on the southeast corner may lose access to the westmost driveway.

These considerations are discussed in further detail throughout the report.

2. Background Information, Procedures, and Design Criteria

2.1 Background Information

2.1.1 Project Location

The project location is in Merriam, Kansas – refer to *Figure 2.1* below. The project extents are limited to Johnson Drive bridge over Turkey Creek and the length of roadway needed to tie the bridge back to existing features.

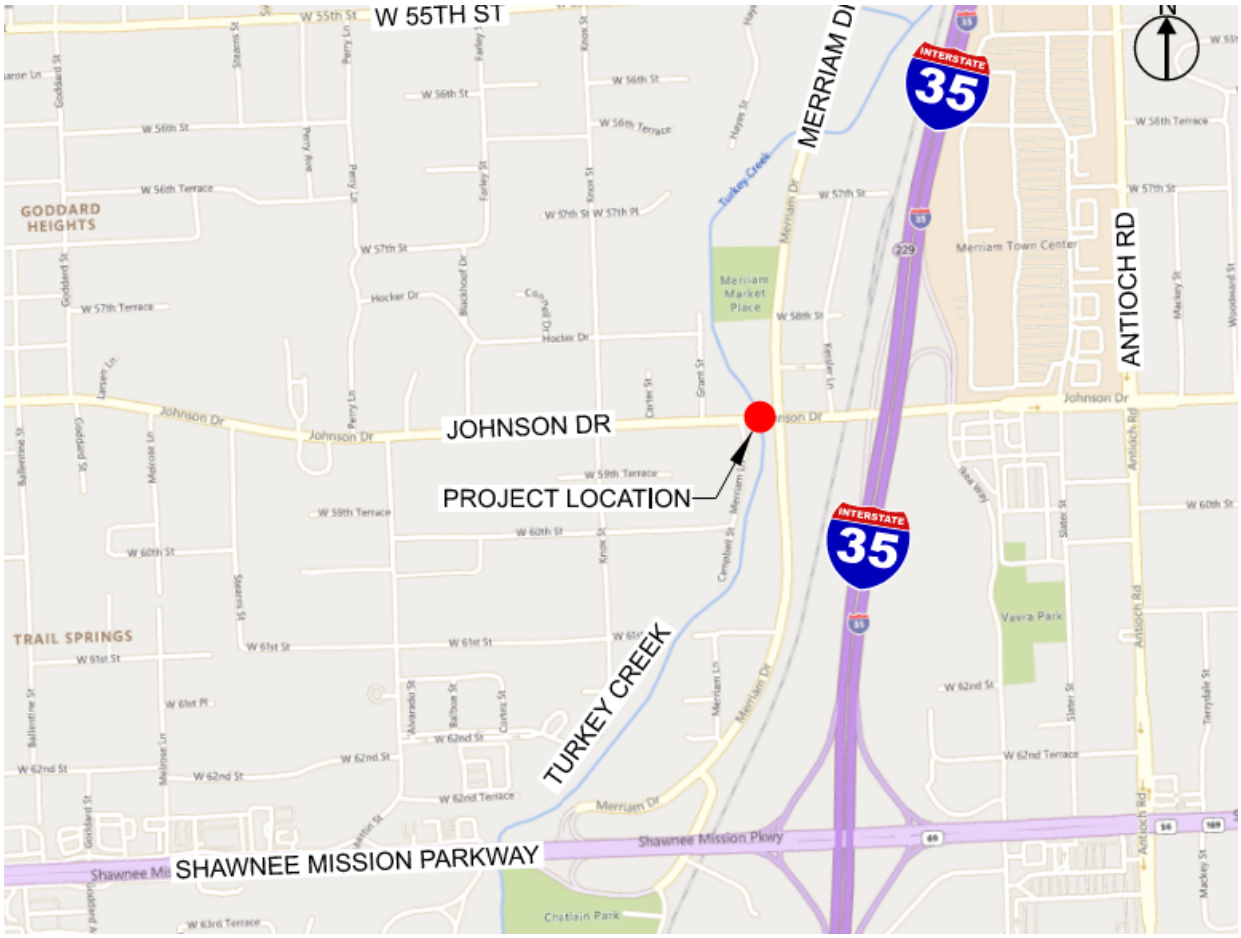

Figure 2.1 – Project Location Map
(Source: Bing Imagery)

2.1.2 Project Purpose

The Upper Turkey Creek study focuses on flood risk management at the Johnson Drive Bridge over Turkey Creek. USACE completed the Upper Turkey Creek Basin Flood Risk Management Study in 2015 (herein referred to as "2015 Feasibility Study") and identified problems such as:

- Severe flash flooding with low response time
- Loss of life due to flooding
- Property damage to commercial/industrial properties
- Damage to infrastructure
- $3.5M in estimated annual damages

This report aims to develop an approach to reduce the risk of severe flash flooding by analyzing various bridge and channel options for Johnson Drive over Turkey Creek. Proposed alternatives do not rely on emergency response crews to provide closures or evacuations due to the rapid rise in water surface elevation (WSEL).

2.1.3 Drawing Backgrounds

Figures and exhibits displayed in this report use the USACE-provided 2023 topographic and boundary survey information. Johnson County Automated Information Mapping System (AIMS) planimetrics and property information were used to supplement the 2023 topographic survey.

Existing utility drawings were compiled using as-built drawings from utility owners. The 2023 USACE Subsurface Utility Exploration (SUE) and AIMS were used to verify utility locations but are not displayed in any background drawings.

The existing terrain was modeled using AIMS contours. While 3D topographic survey was provided by USACE, no terrain model was provided.

2.2 Existing Features

2.2.1 Existing Johnson Drive Bridge

The existing bridge was constructed in 1981, and the superstructure was reconstructed in 2014. The bridge consists of 49.4'-50.4'-49.5' composite steel rolled beam spans supported by pile bent abutments and concrete column bent piers founded on drilled shafts, as seen in *Figure 2.2* to the right. The total superstructure depth is approximately 3.0' from top-of-deck to bottom-of-steel-beam.

Figure 2.2 - Existing Johnson Dr Bridge

The bridge section totals 75'-4" in width. The section includes five (5) 11' lanes and 5' sidewalks on both sides of the roadway.

The low steel elevation is approximately 911.7', while the lowest deck elevation is approximately 914.5'. The 1% annual exceedance probability (AEP) elevation is 918.47' at the upstream (south) face of the bridge and 917.95 at the downstream face. Due to the longitudinal grade of the roadway, only the east end of the bridge overtops during the 1% annual exceedance probability (AEP) high water event.

The steel beams of the existing bridge are susceptible to being damaged by large floating debris during flooding. A replacement bridge should have adequate freeboard above flood waters or be robust enough to avoid damage if impacted by debris.

2.2.2 Existing Johnson Drive Roadway

Johnson Drive is a minor arterial roadway consisting of a 5-lane section with 11-foot lanes and curb and gutter. The roadway has a posted speed limit of 35mph, and design speeds will be assumed to match the posted speed limit. Johnson Drive serves as a primary link between I-35 to the east and the cities of Merriam and Shawnee to the west.

2.2.2.1 Horizontal Geometry

Section 1.2 of AASHTO's *A Policy on Geometric Design for Highways and Streets,* 7th Edition (herein referred to as GDHS-7) explicitly states: "If some aspects of the geometric design for a road or street do not fully comply with the geometric design criteria…but the road or street is performing satisfactorily, there is no need to change those aspects of the existing geometric design for projects in which the basis roadway type will remain the same". There is currently no available data suggesting the existing roadway performs inadequately. Further, the alignment, typical section, and function of Johnson Drive are remaining unchanged. Therefore, geometric deficiencies are solely discussed in this section for

acknowledgement and to suggest a possible resolution for future consideration if determined feasible within the parameters of the project.

At the west end of the bridge, the existing lane shift taper length is 75'. Refer to *Figure 2.3* below for a figure showing this taper. AASHTO GDHS-7 Equation 3-39 (shown to the right) derives required lengths of tapers for roadways with design speeds less than 45-mph. AASHTO GDHS-7 Section 3.4.4.1 also specifies that a lane addition taper can be half the length determined by AASHTO GDHS-7 Eq. 3-39. For a design speed of 35-mph and width transition of 11', a taper length of 115' is recommended.

$$L = W * S^2/60$$ *(AASHTO GDHS-7 Eq. 3-39)*

Where:

- *L = Length of Taper (ft)*
- *W = Width of Taper (ft)*
- *S = Design Speed (mph)*

The two most reasonable options for correcting the issue are to widen the eastbound lanes to the west or restripe the taper with a shorter left turn lane at Merriam Drive. The widening option, in conjunction with the revised profile along Johnson Drive, may have adverse property impacts on the southwest corner of the Johnson Drive and Campbell Lane intersection. Restriping the taper to shorten the left turn lane should only be done after performing a traffic analysis to verify the Johnson Drive and Merriam Drive intersection would continue to operate sufficiently. Both options should be vetted in more detail if this project goes to full design.

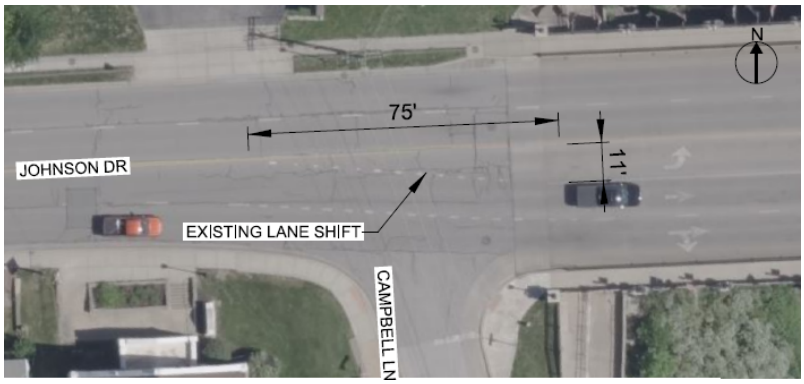

Figure 2.3 - Johnson Dr Taper at West Edge of Bridge

At the east side of the Johnson Drive and Merriam Drive intersection, another lane shift taper is used to develop a left turn lane, as shown below in *Figure 2.4*. This taper is an adequate length for the 35-mph roadway. It should be noted that BNSF Railway ROW begins approximately 60' beyond the existing end of taper, and the BNSF ROW should be avoided.

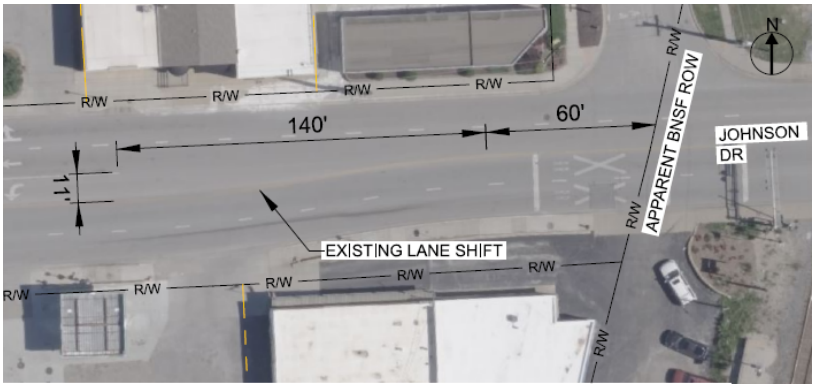

Figure 2.4 - Johnson Dr Taper at East Extent of Study

2.2.2.2 Merriam Drive Intersection

The intersection of Johnson Drive and Merriam Drive has several inadequacies or inefficiencies. The curb return radii in the western half of the intersection promote traffic turning into improper lanes – vehicles will turn into the outermost lane of the receiving roadway, as seen below in *Figure 2.5*. Merriam Drive has inefficiencies with the existing lane configuration, as shown below in *Figure 2.6*. Southbound Merriam Drive has a right turn lane with a storage length of 35', enough for approximately two (2) vehicles and not enough length to allow vehicles to enter the turn lane if there is a queue for the through movement. South of the Johnson Drive intersection, the westmost lane is dropped. This lane could be removed without any negative impacts to traffic flow. Removing these lanes could provide more room for flood control measures while providing the opportunity to correct the intersection curb return radii.

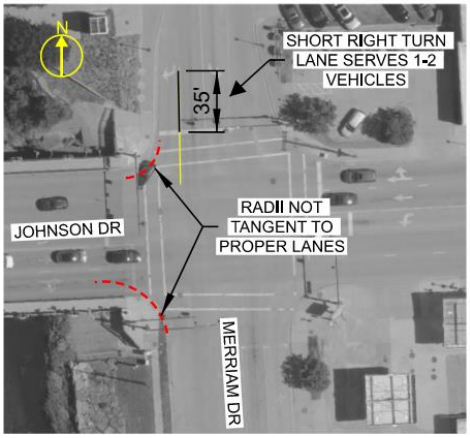

Figure 2.5 - Intersection Radii

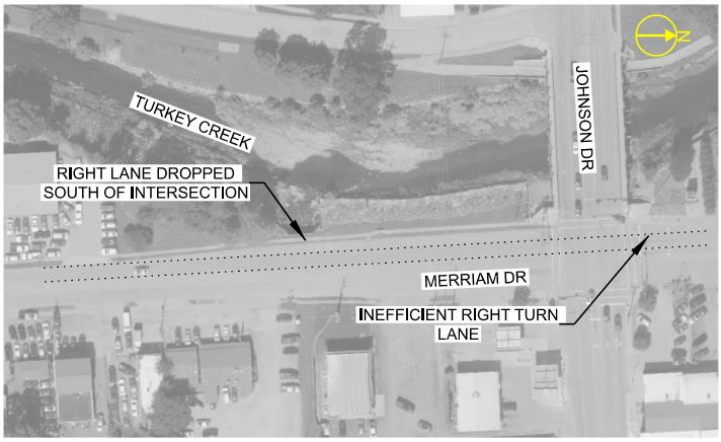

Figure 2.6 - Merriam Dr Potential Lane Reduction

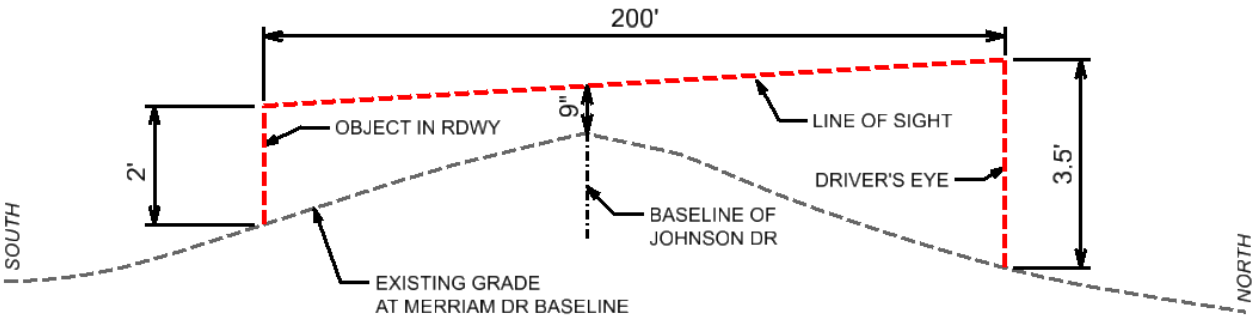
2.2.2.3 Merriam Drive Roadway

The Merriam Drive roadway is also a minor arterial roadway, per the Mid-America Regional Council (MARC) Functional Classification Map. The existing posted speed limit is 30-mph; therefore, the design speed is set at 30-mph in this report. While no realignment is required, Merriam Drive can undergo a lane reduction to provide additional space for flood protection measures. In fact, the City of Merriam has

worked to develop draft plans that show Merriam Drive reduced to a three-lane section north of Johnson Drive.

Existing Merriam Drive provides adequate stopping sight distance (SSD) through the Johnson Drive intersection. SSD is discussed in Section 3.2.6 of AASHTO GDHS-7 – where an SSD of 200' is required for a 30-mph roadway. The driver's eye height should be assumed to be 3.5', and the object height should be assumed to be 2.0'. Using this analysis method, *Figure 2.7*, shown below, illustrates the existing SSD. Note that any grade raises of 9" or more for Johnson Drive are likely to impede SSD. Combinations of vertical curvature and flattening of the cross slope of Johnson Drive should be utilized to mitigate SSD impacts from any Johnson Drive grade raises.



MERRIAM DR PROFILE
(Looking West)

Figure 2.7 - Merriam Dr SSD

2.2.3 Existing Utilities

Identification of existing utilities was coordinated with the concurrent USACE Task 1: Utility Analysis project. Utilities were initially determined via OneCall, and all known utilities were contacted for as-built plans. The following utilities have been identified within study limits:

Table 2.1 - Identified Utilities

Identified Utilities				
Owner	**Facility Type**		**Owner**	**Facility Type**
AT&T	Fiber		City of Merriam	Storm Sewer
Everfast	Fiber		Evergy	Electric
Google Fiber	Fiber		Johnson County Wastewater	Wastewater
Spectrum	Fiber		Kansas Gas	Gas
Verizon	Fiber		WaterOne	Water

Notably, the existing bridge over Turkey Creek has nine (9) conduits running between girders, as seen in *Figure 2.2*. The proposed bridge section will consider providing a location for conduit along the bridge.

2.2.4 Existing Right-Of-Way (ROW)

Figure 2.8, shown below, depicts the existing ROW through Downtown Merriam. It should be noted that ROW varies constantly throughout the Johnson Drive corridor, and ROW on the east/west sides of Turkey Creek is inconsistent. As seen in the figure below, the eastern limits of the project are bound by the BNSF Railway ROW. Caution should be taken to avoid impacts to the BNSF Railway ROW.

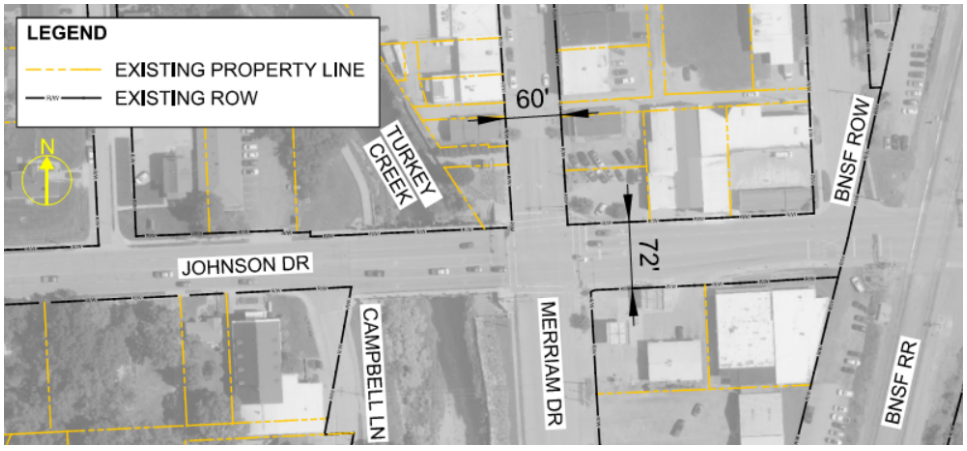


Figure 2.8 - Existing ROW

2.3 Design Criteria

Design criteria were developed in accordance with the latest guidance/policies published by AASHTO and KDOT. For a full listing of roadway design criteria and sources, refer to *Table A.1* in Appendix A.

3. Project Approach

3.1 Approach to Alternative Development

The driving factors for the overall Upper Turkey Creek Project are outlined in Section 2.1.2 of this report. Any Johnson Drive bridge project alternative should aim to address all factors driving the overall project.

In the 2015 Feasibility Study, channel widening and levees/floodwalls were discussed as Upper Turkey Creek Flood Risk Management approaches. These approaches were incorporated into Johnson Drive bridge alternative development alongside site-specific considerations.

The study team identified that the interfacing of bridge design and the hydraulic principles driving the project offers a methodology to analyze project impacts holistically. Ultimately, the goal of the project is to reduce risk for downtown Merriam's safety, properties, and infrastructure. At a high level, there are two (2) related variables that can be changed on this project to achieve the project's goals: WSEL and bridge profile elevation. Alternatives should utilize a combination of these two (2) factors to address the flooding problem.

3.1.1 Water Surface Elevation (WSEL)

The 1% AEP WSEL of Turkey Creek is the primary driving force behind the need for the Johnson Drive bridge project. In the current state, a 1% AEP event would overtop Johnson Drive and Merriam Drive and flood downtown Merriam. Any improvements will need to provide a continuous barrier to prevent future flooding.

At a simplified level, the WSEL is a function of the volumetric flow rate (constant in any alternative), velocity of flow, and cross-sectional area of the flow. Alternatives can alter the velocity of the flow through the reduction of obstructions to the waterway. While channel roughness can also alter the velocity of the flow, channel roughness was not analyzed as part of this project. Alternatives can alter the cross-sectional area of the flow through channel widening or an increase in channel depth (measured from the bottom of the channel to the low chord of the bridge). In summary, the design can widen the channel or raise the bridge to improve the cross-sectional area for Turkey Creek.

It should be noted that improvements to the hydraulic efficiency of Turkey Creek upstream or downstream of the Johnson Drive bridge may also have positive impacts on the WSEL at the Johnson Drive bridge, but analysis to the upstream and downstream reaches of Turkey Creek are outside of the scope of this study.

A lower WSEL will lead to reduced impacts to surrounding infrastructure and properties.

3.1.2 Bridge Profile Elevation

The bridge profile elevation is directly affected by bridge type through structure depth and freeboard requirements. In general, lower bridge profile elevations will lead to reduced impacts to the surrounding infrastructure and properties.

3.2 Evaluation Matrix

Evaluation matrices were created to quantitatively assess project approaches. This section of the report will discuss the development of the evaluation matrices with thorough explanations of the evaluation categories, weighting of the categories, scoring of the matrix, and alternatives considered by the matrix.

3.2.1 Evaluation Categories

Evaluation categories were developed to rank project approaches against the goals of the project. Meetings were conducted with USACE and the City of Merriam to develop evaluation categories that reflect the interests of all project stakeholders, and the following categories were determined.

3.2.1.1 Costs

Description

Costs were comparatively analyzed between alternatives for evaluation purposes. To facilitate comparisons, costs were discretized to fully understand the impacts of each alternative. For example, different bridge types will have different construction costs; however, each may also have different impacts on ROW or impacts to adjacent infrastructure. As these variables are separate yet positively correlated, the general cost factor was divided into subcategories.

Scoring

The optimal project would minimize total costs and impacts across all subcategories.

Subcategories

Subcategories for the cost grouping are explained below:

- *Bridge* – an estimate of the structure's costs
- *Impacts to Adjacent Infrastructure* – relative estimate of roadway, sidewalk, trail, stormwater facilities, signals, lighting, etc. that are impacted
- *Utility Relocations* – relative estimate of how many utilities will need relocated and ability to accommodate these utility relocations
- *ROW/Easements* – estimate of total property impacts incurred
- *Miscellaneous/Aesthetics* – grouping of uncategorized costs/impacts such as additional aesthetic features, flood control measures, etc.

3.2.1.2 Capacity for Levee Over Floodwall

Description

This category offers insight into how an alternative may influence the ability to utilize a levee rather than a floodwall. Levees are generally preferable to floodwalls due to maintenance considerations, appearance, constructability, and cost. However, levees require much more room to construct. Therefore, an alternative that requires the acquisition of ROW (e.g. such as the closure of a road due to widening the channel to the west) may provide a serendipitous benefit such as more available room in which to construct a levee rather than a floodwall.

Scoring

Alternatives that provide more ROW or more opportunity to construct levees instead of floodwalls rate higher.

3.2.1.3 Maintenance of Traffic (MOT)/Construction Length

Description

Johnson Drive is a minor arterial roadway in Johnson County and is the primary east/west access to downtown Merriam. Any closures of Johnson Drive will result in delayed travel times to/from I-35 for populations west of Turkey Creek. If the Johnson Drive bridge is closed for construction, traffic will have to detour south to Shawnee Mission Parkway to access I-35; this is approximately a 1.1-mile detour that would have to pass through two (2) additional traffic signals. The MOT category is a measure of the ability to manage traffic and travel delays during construction. One factor affecting MOT is the ability to maintain traffic on the existing structure during construction of the new structure. Overall impacts also factor into the MOT/construction length where greater impacts will lengthen the timeline, and larger profile grade raises will reduce the ability to accommodate traffic during construction.

Scoring

An optimal project would reduce the total traffic impacts and length of any construction activities.

3.2.1.4 Impacts to Natural Environment

Description

In any project, limiting impacts to the natural environment is ideal. For this specific study, there is extra importance due to the proximity to a waterway (Turkey Creek) and the stakeholders' relationships with Turkey Creek. The Turkey Creek Streamway Trail, a very popular trail in the region, follows parallel to Turkey Creek, and passes under the Johnson Drive Bridge. A major draw of the Turkey Creek Streamway Trail is the natural feeling provided by Turkey Creek's streambed. This category offers insight into how much an alternative will impact the existing natural environment.

Scoring

An optimal project would reduce the impacts to the stream and preserve natural areas.

3.2.2 Evaluation Category Weighting

To balance the evaluation matrix in the best interests of the project, each category was weighted within the matrices. Weights range from 1 to 5, with a higher weight indicating increased importance for the project. Discussion on how the weight is applied is provided in the next section of this report. Weights are as shown below in *Table 3.1*.

Table 3.1 – Weighting by Category

Weighting by Category			
Costs		**Other Categories**	
Category	**Weight**	**Category**	**Weight**
Bridge	2	Capacity for Levee Over Floodwall	5
Impacts to Adjacent Infrastructure	2	MOT/Construction Length	3
Utility Relocations	2	Impacts to Natural Environment	1
ROW/Easements	2	-	-
Miscellaneous/Aesthetics	1	-	-
Total	**9**	**Total**	**9**

It should be noted that the cost categories are equivalent in total weight (9) to all other categories (9). Intentionally, costs were weighted as a very high factor for this study due to overall Upper Turkey Creek project costs. Costs are also an indicator of overall impacts to existing features – costs are positively correlated with expected impacts.

While costs and impacts gain the majority of the weight in this evaluation matrix, weight needed to be provided to other considerations such as flood control approach, intermediate-term impacts to downtown Merriam traffic, and impacts to nature.

3.2.3 Evaluation Matrix Scoring

Each alternative was analyzed in each evaluation category. A score of 0-5 was assigned and placed to the right of the alternative in the matrix. A score of 0 indicates no direct influence on the evaluation category, a score of 1 indicates poor performance in the evaluation category, and a score of 5 indicates exceptional performance in the evaluation category. Overall, a high total score indicates more potential to address the issues at a project-specific level. While scores are based in engineering judgment, some subjectivity is built into the matrix. All scores represent the engineers' best judgment in comparison with other alternatives.

After scores have been assigned, a total score is developed using *Equation 3-1*, shown below:

$$\sum_{i=1}^{X} C_i * W_i = T \qquad (Eq.\ 3\text{-}1)$$

Where:

- C_i = *Category Score in Column i*
- W_i = *Weight of Column i*
- T = *Total Score*
- X = *Final Column in Evaluation Matrix*

A sample calculation for an individual alternative can be found in Appendix C.

3.3 Alternatives Considered

Two (2) main methodologies to address the problems are identified within this report. These methodologies are Project Approach and Bridge Type. Further discussion on the methodologies is included in the following sections of this report. Three (3) alternatives were considered for each methodology, for a total of six (6) alternatives considered. These methodologies are not exclusive – alternatives from each methodology can be combined. The purpose of this alternative development method is to identify the most effective approach to address all project-specific issues.

3.3.1 Project Approach

The Project Approach alternatives are intended to identify how different approaches can influence the engineering principles discussed in Section 3.2 of this report. Essentially, the evaluation matrix examined the impacts incurred by reducing the WSEL or increasing the roadway profile through three (3) alternatives. Hydraulic analysis for channel alternatives within the Project Approach was completed by USACE.

3.3.1.1 Raise Bridge Deck

Overview

This alternative focuses solely on raising the bridge profile to accommodate the necessary WSEL and does not alter the Turkey Creek channel. The base assumption for comparison is to raise the bridge deck to the optimal profile as discussed in Section 4.3.4.

Pros

- No impacts to Turkey Creek.
- Bridge costs expected to be lower due to no increase in structure length.
- Assumed to offer a reduction in WSEL due to no pressurized flow (this was not modeled).

Cons

- Results in most impacts to infrastructure, properties, and utilities due to grade raise required for the bridge profile.
- Likely to be most costly alternative.

Score: 27

3.3.1.2 Widen Creek Channel to West

Overview

This alternative widens the existing Turkey Creek channel 30' to the west.

Pros

- Offers a reduction of approximately 4" in WSEL. Additionally, the lower WSEL propagates upstream for about a half mile.
- Although the profile elevation change is minor, it is expected to decrease impacts to infrastructure, utilities, and ROW/Easements along Johnson Drive and Merriam Drive.
- May allow for space alongside the west bank of Turkey Creek for levees instead of flood walls to the south.
- Any additional channel improvements downstream would likely improve the returns gained by widening to the west.

Cons

- Longest bridge of any project approach alternative analyzed.
- Campbell Lane would be required to be closed permanently, negatively impacting access to Merriam Christian Church and a few residences to the south.
- Access to Merriam Christian Church would need to be reimagined; likely being reconstructed from Johnson Drive.
- More utility relocations along Campbell Lane would be added to the project.

Score: 38

3.3.1.3 Widen Creek Channel to East

Overview

This alternative widens the existing Turkey Creek channel to the east 10' through the reduction of the westmost turn/merge lanes of Merriam Drive.

Pros

- Offers a very minor reduction in WSEL due to increased cross-sectional area.
- Impacts to infrastructure, utilities, and ROW/Easements may be marginally reduced due to the decreased bridge profile elevation.

Cons

- Bridge costs would be moderately raised due to increased length of the bridge.
- Utility relocations along Merriam Drive would be added to the project.
- Benefits realized don't justify the costs to implement.
- Would eliminate the option to improve the radial returns at the Merriam Drive intersection.
- May make the construction of flood walls more challenging on the east side of Turkey Creek.

Score: 30

3.3.2 Bridge Type

The Bridge Type alternatives were intended to identify how different bridge types may reduce impacts to existing features and potentially provide hydraulic efficiencies that could reduce the WSEL.

A steel rolled beam structure with bents (like the existing bridge structure) was briefly considered but ruled out due to significant limitations. Structure depth, susceptibility to damage from debris, floating concerns, and freeboard requirements compare less favorably to the other alternatives outlined below.

3.3.2.1 Reinforced Concrete Box Culvert

Overview

This alternative was developed by USACE and suggests replacing the existing girder bridge with an RCB culvert. Refer to *Figure B.1* in Appendix B for a graphic representation of the RCB culvert.

Pros

- Low bridge cost.
- Functions similar to a concrete haunched slab bridge.

Cons

- Span and size required eliminates precast RCB options and would necessitate forms, which would be no different than a haunched slab bridge.
- Would have more obstructions (i.e. walls) in the channel than other options.
- Walls typically built on strip (spread) footings, which is more difficult to do in a channel than drilled shafts.

- If constructing a bottom floor, would need to phase out construction more and redirect channel flow around initial box being constructed, which is invasive to the natural channel.
- Kansas Division of Water Resources will require at least one cell, if not all cells, to be buried below natural channel bed to allow for aquatic wildlife passage, negating any positive effects that could be realized with the smooth cell floors.
- More likely to experience debris accumulation at upstream end of RCB than other options.

Score: 14

3.3.2.2 Shallow Superstructure (Haunched Concrete Slab Bridge)

Overview

This alternative was developed to analyze the effects of using a bridge type with a shallow structure depth. By reducing the structure depth, the required bridge profile elevation for a given WSEL is reduced. The primary bridge type considered for this alternative is the haunched concrete slab bridge.

Pros

- Relatively low bridge cost.
- Lower bridge deck elevation will lead to reduced impacts to adjacent infrastructure and utilities.
- Relatively quick construction that regional construction crews are accustomed to.
- Very robust structure; nearly impervious to damage from floating debris.
- Requires less freeboard than other options.

Cons

- Haunched concrete slab bridges require construction falsework that reduces the design waterway during construction.

Score: 16

3.3.2.3 Remove Midspan Bents

Overview

This alternative was developed to analyze the effects on hydraulics by removing midspan bents. However, a hydraulic analysis conducted by USACE determined that removing the bents from the Johnson Drive Bridge had little effect on the WSEL. Bridge types primarily considered for this alternative included truss and arch bridges.

Pros

- High aesthetic value – would add a gateway architecture piece to downtown Merriam.
- Minimized natural impacts – no structural elements located in the stream would minimize the bridge's influences on the stream.

Cons

- High bridge cost due to complexity of structures and steel components.

- Ineffective at lowering grade raise required for Johnson Drive Bridge; would have the greatest impacts to surrounding infrastructure.
- Would be the most expensive overall option.

Score: 8

3.4 Recommended Alternative Selection

The suggested design approach combines the top-scoring project approach (widen creek channel to west) and top-scoring bridge type (haunched concrete slab bridge) to produce a recommended alternative. For more discussion on the recommended alternative, refer to later sections of this report.

4. Design Approach

This section discusses the development of the recommended alternative, starting with the project approach and bridge type identified in the previous section.

4.1 USACE Hydraulic Analysis

To develop the recommended alternative civil site design, the water surface profile for Turkey Creek was needed. USACE completed hydraulic analysis of two options: the existing bridge (shown in *Figure D.1* of Appendix D) and a concrete haunched slab bridge (shown in *Figure D.2* of Appendix D).

Another model (no exhibit included in this report) was ran by USACE that combined the concrete haunched slab bridge with a channel widened 30' to the west of the existing west abutment of the Johnson Drive Bridge. A water surface profile (shown in *Figure D.3* of Appendix D) was provided by USACE to show the assumed water surface profile at the upstream edge of the Johnson Drive bridge.

Table 4.1 – Key Water Surface Elevations

Key Water Surface Elevations		
Location	**Widening WSEL**	**No-Widening WSEL**
West Abutment	918.07	918.47
East Abutment	918.27	918.62

The key WSELs from each model are shown in *Table 4.1* to the left. A widened channel drops the water surface profile by an average of 0.38', effectively reducing the required bridge profile and flood protection elevation by the same amount. It should be noted that in both alternative models ran, the models assumed pressurized flow at the bridge.

4.2 Typical Sections

Typical sections were developed for Johnson Drive, the Johnson Drive Bridge, and Merriam Drive to show a section view of the proposed civil features. Refer to Appendix E for typical section exhibits.

It should be noted that the profile grade line of Johnson Drive in exhibits is drawn at the baseline for the roadway, and an elevation drop will occur from the baseline to the upstream edge of the bridge, as seen in *Figure E.1*. This drop is calculated at a rate of 2% over 35', for a total drop of 0.70'.

4.3 Vertical Design

4.3.1 Profile Grade Criteria

Criteria for the vertical design is shown in *Table A.1* in Appendix A. Minimum sag vertical curve K-values are a controlling factor for the tie-ins of Johnson Drive and Merriam Drive east of the Turkey Creek bridge.

4.3.2 Existing Profile Grade Elevations

The existing profile grade elevations (as found in the topographic survey from 2023 provided by USACE) at the east and west abutments are shown to the right in *Table 4.2.* Elevations were checked against AIMS surface contours and verified to be accurate.

Table 4.2 – Existing Elevations

Existing Profile Grade Elevations	
Location	**Elevation**
West Abutment	919.78
East Abutment	914.89

4.3.3 Profile Grade Constraints

To determine the extents of the horizontal geometric layout necessary to accommodate a raised bridge over Turkey Creek, the bridge profile must first be created. In *Figure 4.1*, shown below, the factors influencing the profile grade of the roadway over Turkey Creek are displayed.

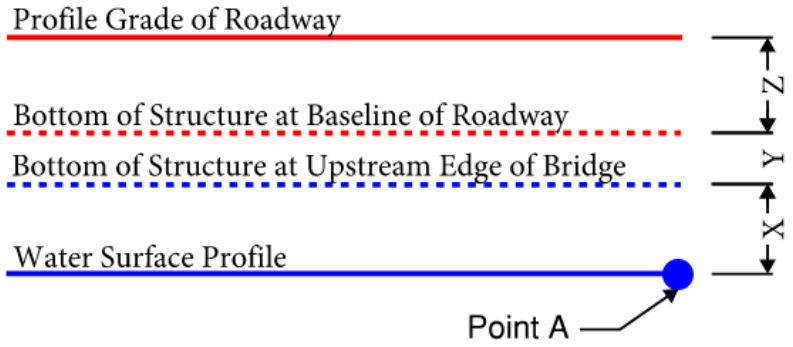

Figure 4.1 – Factors Influencing Bridge Profile Grade

The bridge profile has a critical point for determining elevation, indicated in *Figure 4.1* above by "Point A". Point A is where the elevation difference between the bridge low chord and the water surface is at its lowest. Assuming that the widened channel will be the base condition moving forward, this critical point occurs at the east abutment of the Johnson Drive bridge with an elevation of 918.27 (*Figure 4.1*).

Using the critical point, the elevation of the roadway at the east abutment can be calculated using *Equation 2*, shown below:

$$EL_{PGL} = WSEL_A + X + Y + Z \text{ (Eq-2)}$$

Where:

- EL_{PGL} = *Elevation at Profile Grade Line of Johnson Drive*
- $WSEL_A$ = *Water Surface Elevation at Point A*
- X = *Freeboard*
- Y = *Elevation drop from baseline of bridge to upstream edge (Refer to Section 4.2 of this report for information relating to the elevation drop)*
- Z = *Depth of Structure*

4.3.4 Optimal Profile Grade

Optimally, the bridge would be able to clear the 1% AEP WSEL and provide freeboard. If preferred values of freeboard are met (X = 2'), the equation for the elevation of the Johnson Drive profile grade line is as follows in Equation 2:

$$EL_{PGL} = 918.27 + 2' + (2\% * 35') + 18.5" = 922.51 \text{ (Eq-2)}$$

The plan and profile of Johnson Drive required to meet the profile grade elevation shown in *Equation 2* is shown in *Figure F.1* of Appendix F.

While this option is hydraulically optimal, the impacts to surrounding facilities are greatly increased by the significant increase in profile grade. *Table 4.3*, shown below, summarizes the grade difference between the optimal profile grade elevation and the existing grades.

Table 4.3 – Optimal Profile Raise

Elevation Differential			
Location	**Optimal Profile Elevation**	**Existing Grade**	**Grade Difference**
East Abutment	922.51'	914.89'	7.62'

4.3.5 USACE-Provided Conceptual Profile

USACE provided the study team with a proposed conceptual profile for Johnson Drive (refer to *Figure B.2* in Appendix B). The profile was received in image format. Therefore, to analyze the profile and assess potential impacts, elevations were interpolated using the embedded grid.

The profile elevation at the east abutment was estimated to be approximately 916.3', which sits approximately 2.3' below the no-widening WSEL (918.62') noted in *Table 4.1*. This was supported in

subsequent discussions with USACE, who confirmed pressurized flow was assumed with their conceptual design.

Although the USACE profile is an improvement over the existing condition, elevations at the east abutment fall short of what is required to raise the bridge completely out of the 1% WSEL. Using the recommended haunch slab bridge, along with the premise that pressurized flow would be acceptable, HNTB analyzed several profile options to reduce the risk of flooding while balancing impacts to surrounding infrastructure and property.

4.3.6 Allowable Profile Grade

Haunched concrete slab bridges offer many advantages when compared to other bridge types when considering hydraulic forces exerted upon the bridge.

- Buoyant forces are minimized due to the geometry of the bridge – negligible amounts of air are trapped between the bridge and the water during a flood.
- Resistance to overturning due to weight and width of bridge - water pressure acting upon the bridge can be accommodated in design.
- Barrier walls can be constructed at bridge fascias to tie into floodwalls to reduce or eliminate overtopping of the bridge.

Therefore, due to the ability to resist forces from floodwaters and the ability to maintain floodwall continuity across the bridge, the haunched concrete slab bridge can have the freeboard reduced to 1', or even eliminated. An alternative showing a profile grade where the bridge is partially in the water is depicted in *Figure F.2* in Appendix F.

While not analyzed in the draft phase of this study, the bridge profile will have effects on the WSEL. If the bridge profile provides more length along the bridge with freeboard, there could be improved WSELs. However, additional interference with the flow due to structures will lead to worsened WSELs at the Johnson Drive bridge. Further iteration of hydraulic analysis is needed to determine the water surface profile of any suggested bridge profiles.

5. Recommended Civil Design

The recommended civil design combines the following recommendations throughout this report:

- Widen Turkey Creek channel to the west (Section 3.3.1.2)
- Replace the existing bridge with a concrete haunched slab bridge (Section 3.3.2.2)
- Allow bridge to be under pressurized flow (Section 4.3.5)
- Profile changes to Johnson Drive and Merriam Drive (Section 4.3.6)

The drawings for the recommended civil site layout can be found in Appendix F in *Figures F.2*, *F.3*, and *F.4*.

It should be noted that all estimated property impacts are based on USACE-provided topographic survey and, where necessary to fill in gaps, contours and elevation data obtained from AIMS. The smallest contour intervals are limited to 2' and it is unknown what level of error they contain. Visual examination in the field suggests there may be opportunity to mitigate many of the impacts during more detailed design.

5.1 Bridge Profile Over Turkey Creek

For a view of the Johnson Drive profile, refer to *Figure F.2* in Appendix F. The proposed profile is located below the 1% AEP WSEL for most of the length of the bridge; however, the west portion of the bridge clears the 1% AEP WSEL. To minimize the risk of flooding, it is recommended to include integral structural barrier walls along the bridge fascia. The barrier walls would tie-in to the adjacent floodwalls to provide continuity and reduce the potential for floodwater to overtop the bridge.

5.2 Potential Impacts East of Turkey Creek

The downtown Merriam area is expected to be moderately impacted. Refer to *Figure F.3* in Appendix F for an exhibit showing civil features east of Turkey Creek.

North of Johnson Drive, six (6) properties are estimated to be impacted. Of the six (6) properties impacted, four (4) include structures that may impacted by the roadway improvements. Structures were identified as impacted if grades were raised by 6" or more at any point in the building footprint. If grades were raised by less than 6", it was assumed that design of the roadway and sidewalk may be able to mitigate the grade raise and avoid impacts. Refer to Figure G.4 in Appendix G for conceptual property impacts for the recommended option. It should be noted that many of the buildings have a step up from the sidewalk into the doorway – sidewalk grade raises up to the door level should be considered a practical approach to keep the structure intact. If sidewalk grades are raised above the door level, the property should be considered for a total acquisition.

South of Johnson Drive, the BP gas station on the southeast corner may lose driveway access immediately east of the intersection due to profile grade changes. At this location, Johnson Drive is anticipated to be

approximately 1.5' higher than the existing elevation. If realized, there is potential for this to cause a significant loss of use for the business and could result in the property as a total acquisition.

5.3 Potential Impacts West of Turkey Creek

Due to the widened Turkey Creek channel, Campbell Lane will need to be closed from Johnson Drive to W 60th Street. Refer to *Figure F.4* in Appendix F for an exhibit depicting civil features west of Turkey Creek

Currently, Campbell Lane only serves one (1) property between 60th Street and Johnson Drive – the Merriam Christian Church. To continue service to the church's parking lot, there are a couple of possibilities. One option would be to convert Campbell Lane to a one-way driveway in tandem with the existing driveway located off Johnson Drive. However, this option limits the available space for levee construction. An alternative solution would be to reconstruct and widen the existing driveway off Johnson Drive to allow two-way traffic. In this scenario, parking lot access to Campbell Lane would be closed and all access to the church would enter and exit from Johnson Drive. The existing driveway sits primarily on church owned property. The house between the church parcels, located at 9417 Johnson Drive, appears to potentially be vacant. Purchase of the house could be investigated to provide a wider, safer commercial entrance along Johnson Drive.

The other primary consideration for channel widening is the Turkey Creek Streamway Trail. The trail is a key feature for the area and is a critical component of the City's overall pedestrian connectivity plan. Relocation along the new west abutment is assumed as noted on Figure D.3. Design should account for vertical clearance and interaction with the abutment and flood wall. South of the Johnson Drive bridge, the trial could either be shifted west to the vacated Campbell Lane or incorporated into a levee, depending on the flood protection measure implemented.

5.4 Potential Utility Impacts

As noted in Section 2.2.3, an associated and concurrent USACE project is performing in-depth utility analysis and coordination for the Johnson Drive corridor. Full utility coordination and relocation plans require more time and effort than what was covered by this report. Therefore, the information provided is for reference only and no relocation quantities are included, as that level of detail is still unknown.

One important consideration to note is that relocation costs are typically only reimbursed when utilities are located within private easement. When located within ROW, relocation costs are nearly always encumbered by the utility. Therefore, without a more thorough investigation into potential easements, it is assumed that any utility located within existing ROW would be fully responsible for relocation costs.

5.4.1 Evergy

Facilities are generally aerial, with all poles located within ROW, either in the green space at the back of curb or in the adjacent sidewalk. Unless there is a crash history associated with a specific pole, these

conditions are typically allowed to persist. Because there is no roadway widening, we are assuming the current location of all poles is acceptable.

The more likely scenario that may require some pole modifications revolves around a lack of required vertical clearance due to the Johnson Drive profile raise. This could be due to the electrical wires themselves, or the attached fiber utilities located below. There are two poles that may not meet vertical requirements: at the southeast corner of the Johnson Drive and Merriam Drive intersection and approximately 50-ft north of the bridge. However, more information is needed to determine if proposed conditions would be acceptable or if attached utilities could relocate.

For a conservative approach, these two locations could be estimated to be reset with taller poles. However, as noted, it is assumed these costs would be incurred by Evergy.

5.4.2 Johnson County Wastewater

There are two manholes that will need to be raised (southeast corner of the bridge in the approach pavement and approximately 50-ft north of the bridge, next to the Evergy pole). A third manhole located about 17-ft from the edge of pavement in the northwest corner of the Johnson Drive and Merriam Drive intersection may need to be raised and/or modified (e.g. locking/sealed) due to Turkey Creek WSELs. This location would not need to be raised due to profile changes as design components could limit impacts.

Compensability for wastewater manholes is less straightforward. Typically, this is a bid item that is included in the construction of the proposed improvements with the project.

5.4.3 Kansas Gas / WaterOne

Individual valves within the roadway will need to be raised, however, gas and water lines should be located sufficiently deep enough that relocation is not required due to construction activity alone. A common practice in these situations is for contractors to locate and protect lines in place. However, it is possible that either or both utilities may request to have their line(s) relocated for several reasons: concern over the additional 1-ft to 2-ft of coverage, aging line(s) that needs to be replaced, or a desire to upsize their line(s). In such instances, gas and water utilities often take advantage of construction projects as an opportunity to make improvements.

Both gas and water utilities appear to be located within existing ROW and any relocation costs are assumed to be incurred by the respective utility.

5.4.4 AT&T / Everfast / Google / Spectrum / Verizon

All known fiber utility locations are within ROW. Relocation costs are assumed to be the responsibility of each utility owner.

5.5 Quantities

Quantities associated with the recommended design are shown in Appendix G.

APPENDIX A – DESIGN CRITERIA

Table A.1 – Design Criteria

UTC Civil Design Criteria				
Criteria	**Johnson Dr**	**Merriam Dr**	**Sidestreets**	**Source**
Roadway Classification	Minor Arterial	Minor Arterial	Local	MARC Functional Classification

Name	2	2	2	2	1	5	3	1			
Project Approach											
Raise Bridge Deck	3	1	1	1	1	1	3	0	27	Involves raising grades of all surrounding roadways to tie into raised bridge.	
Widen Creek Channel to West	1	4	3	2	2	2	2	0	38	Would involve closure of Campbell Lane from Johnson Drive to 60th St.	
Widen Creek Channel to East	2	2	2	2	1	2	1	0	30	Two Options: A. Fix intersection corner radii by narrowing Merriam Dr to a one-way section north of Johnson Dr. B. Keep existing, inadequate corner radii but reduce scale of issue by removing west-most lane of Merriam Dr.	

Table C.2 – Bridge Type Evaluation Matrix

Alternative	Evaluation Category								TOTAL SCORE	Recommended Alternative
	Costs									
	Bridge	Impacts to Adjacent Infrastructure	Utility Relocations	ROW/Easements	Miscellaneous/Aesthetics	Capacity for Levee Over Floodwall	MOT/Construction Length	Impacts to Natural Environment

$3 * 2 = 6$

Eq 3-1:

- $\sum_{i=1}^{X} C_i * W_i = T$

Values Plugged into Eq 3-1:

- $T = (3 * 2) + (1 * 2) + (1 * 2) + (1 * 2) + (1 * 1) + (1 * 5) + (3 * 3) + (0 * 1) = 27$

APPENDIX G – QUANTITIES

Table G.1 -Quantities

UTC Johnson Drive Replacement Quantities				
Group	**Item**	**Qty**	**Unit**	**Assumptions***
Roadway Paving	2" Asphalt Surface	530	TON	No pavement design completed, density of 150 PCF
	8" Asphalt Base	2,100	TON	No pavement design completed, density of 150 PCF
	6" Granular Base	5,510	SY	Under roadway & approach slab, 1' beyond BOC
	8" Modified Subgrade	5,510	SY	Under roadway & approach slab, 1' beyond BOC
	Curb and Gutter, Type B	2,660	LF	
Other Infrastructure	PCC Driveway (6")	1,085	SY	
	Sidewalk (4")	2,040	SY	Includes trail.
	Integral Sidewalk Retaining Wall (ISRW)	460	SF	Estimated average height of 1.5'
	Tract 10 ISRW	280	SF	Estimated average height of 2.0' See Figure G.4 for Tract numbers.
	15" RCP	120	LF	
	18" RCP	490	LF	
	Curb Inlet	5	EA	
	Storm Outfall	1	EA	
Bridge	Bridge	14,130	SF	Proposed bridge is haunched concrete slab bridge. Estimated at $203/SF (2024), includes structural fascia walls.
	Approach Slab	1,560	SF	Assumes 13' length & BOC-to-BOC width (see Figure F.2)
Lump Sum Items	Roadway Lighting	1	LS	Assumes 19 streetlights to be remove/reset, new bridge lighting, and all existing lighting is sufficient. Assumes light fixtures are not damaged.
	Sodding	1	LS	Non-paved area = 1.3 Acres
	Traffic Signal	1	LS	Assume full replacement of 4 signal assemblies
	Signing and Striping	1	LS	Assume Signing/Striping is 10% of total roadway paving costs.
	Erosion Control	1	LS	Disturbed Area = 3.4 Acres. Includes paved areas.
	Traffic Control	1	LS	Assume Traffic Control is 15% of total Roadway Paving costs.

(TABLE CONTINUES ON NEXT PAGE)

Demolition	Remove Pavement	7,410	SY	Existing pavement depths/types not known. Assume 18” depth.
	Remove Curb and Gutter	3,670	LF	
	Remove Driveway	1,070	SY	
	Remove Bricks	325	SY	Brick pavers in downtown Merriam
	Remove Sidewalk	1,640	SY	Trail included in quantity.
	Remove Bridge Approach	1,191	SF	
	Remove Bridge	11,174	SF	
	Remove 15” RCP	65	LF	
	Remove 15” CMP	90	LF	
	Remove 18” CMP	535	LF	
	Remove Curb Inlet	7	EA	Includes manholes, inlets, and aprons.
	Modify Storm Structure	4	EA	Includes changing top of storm structures to/from inlets.
	Remove Storm Outfall	2	EA	
	Remove Retaining Wall	865	LF	Includes large block, small block, integral sidewalk walls
Earthwork	Cut	2,210	CY	Refer to following sheet for basis of quantity.
	Fill	2,360	CY	Refer to following sheet for basis of quantity.

*Approximated area that may be legally owned by the City of Merriam due to KS Statute 60-503 (Adverse Possession).

G.1 Earthwork Estimation Notes:

Earthwork for the project is based upon conceptual corridor models developed. It should be noted that the existing grade surface was determined from AIMS contours, and surface elevations may not accurately reflect true conditions. All earthwork should be considered conceptual for order-of-magnitude purposes only.

The following assumptions were made for earthwork calculations:

- No fill factor assumed.
- Average end-area method used. Assumed widening to tie-in to existing channel cross-sections 100' upstream and downstream of bridge cross-section.
- Channel widening estimated based on cross-section provided by USACE (see Figure D.3).
- Autodesk Civil 3D TIN Volume Surface volumes are used to compute volumes for any proposed roadway grade changes.

G.1.1 – Channel Widening Volumes

Table G.3 - Channel Widening Volumes

Station*** (Turkey Creek)	Description	Cut Area [SF]	Fill Area [SF]	Cut Volume [CF]	Fill Volume [CF]	Cut Volume [CY]	Fill Volume [CY]
0+00	Start widening	0	0	0	0	0	0
1+00	Full Widening	259*	8*	12,950	400	480	15
2+00	Full Widening	259*	8*	25,900	800	960	30
3+00	End Widening	0	0	12,590	400	480	15
			TOTAL	**51,800**	**1,600**	**2,000****	**100****

*Refer to Figure G.3 for area derivation.

**Due to limited accuracy of input information for channel widening, rounded to one significant digit.

***Stations are arbitrary for measurement purposes and do not match USACE stationing.

Sample Calculations:

$$Cut\ Volume = (Area_2 + Area_1) * (STA_2 - STA_1) * \frac{1}{2}$$

[For Station 1+00] → $(259\ SF + 0\ SF) * (100\ LF - 0\ LF) * \frac{1}{2} = 12{,}950\ CF$

$$12{,}950\ CF * \left({}^{1\ CY}/_{27\ CF}\right) = 480\ CY$$

G.1.2 Civil 3D Generated Volumes:

West of Turkey Creek:

GENERAL

Traffic Information

$ADT := 13920$ *(average daily traffic; SI&A Data, NBI Item 29)*

$ADTT_{percent} := 10\%$ *(average daily truck traffic in percentage of ADT; assumed)*

$ADTT := (ADTT_{percent}) \cdot (ADT) = 1392$ *(average daily truck traffic)*

$v_{PSL} := 35\ mph$ *(posted speed limited)*

$v_{DSL} := 45\ mph$ *(design speed limited; assumed)*

$N_L := 5$ *(number of design lanes)*

$n_L := 3$ *(number lanes with traffic in the same direction)*

Material Properties

$\gamma_c := 150\ pcf$ *(unit weight of concrete)*

$\gamma_w := 62.4\ pcf$ *(unit weight of water)*

Hydraulic Properties

$Q_{US} := 17810\ cfs$ *(upstream flowrate; NWK H&H)*

$V_{US} := 8.8\ fps$ *(maximum upstream velocity; NWK H&H)*

Note: The flat face of the flood wall will have a drag coefficient similar to a square-ended pier.

$(C_D)_{flood.wall} := 1.4$ *(drag coefficient for square-ended pier; LRFD Table 3.7.3.1-1)*

$(C_D)_{pier} := 0.7$ *(drag coefficient for square-ended pier; LRFD Table 3.7.3.1-1)*

Wind Design Properties

$roughness :=$ ground surface roughness d *(ground surface roughness; LRFD 3.8.1.1.4)*

$wind.exposure :=$ wind exposure category d *(wind exposure category; LRFD 3.8.1.1.5)*

$V_{III} := 115\ mph$ *(design 3-second gust wind speed for Strength III; LRFD Table 3.8.1.1.2-1)*

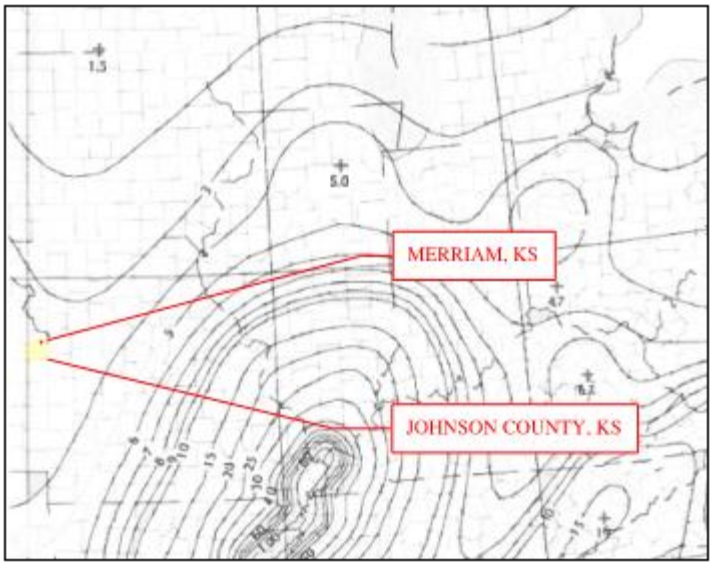
$G := 1.00$ *(gust effect factor; LRFD 3.8.1.2.1)*

$(C_D)_W := 1.3$ *(gust effect factor; LRFD Table 3.8.1.2.1-2)*

Seismic Design Properties

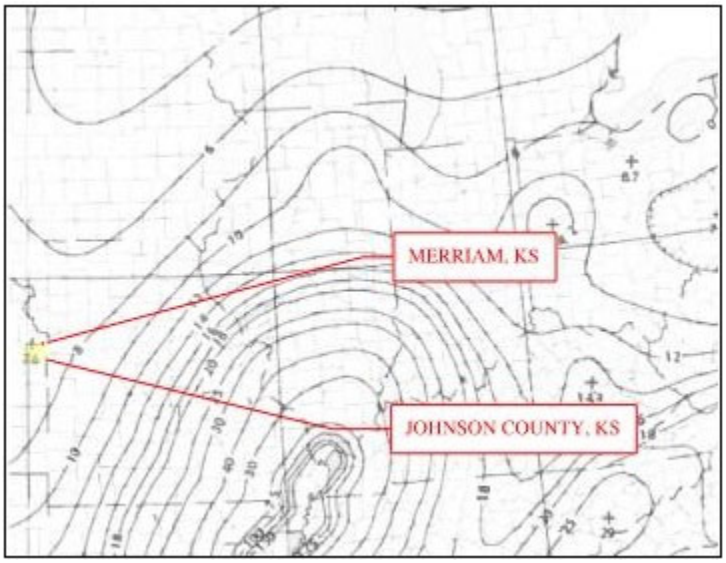
$site.class :=$ "d" *(site classification, assumed)*

LRFD Figure 3.10.2.1-1:



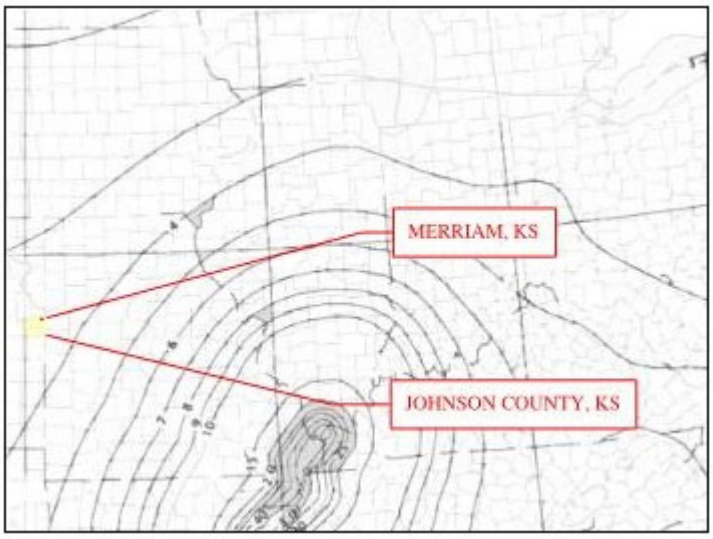
$PGA := 3.5\%$ *(peak seismic ground acceleration coefficient on rock; LRFD 9th Ed. Figure 3.10.2.1-1)*

LRFD Figure 3.10.2.1-2:



$S_S := 7.6\%$ *(horizontal response spectral acceleration coefficient at 0.2-s period on rock - site class b; LRFD 9th Ed. Figure 3.10.2.1-2)*

LRFD Figure 3.10.2.1-3:



$S_1 := 3.7\%$ *(horizontal response spectral acceleration coefficient at 1-s period on rock - site class b; LRFD 9th Ed. Figure 3.10.2.1-3)*

Load and Resistance Factors

Load Modifiers:

$\eta_D := 1.00$ *(load modifying factor for ductility; LRFD 1.3.3)*

$\eta_R := 1.00$ *(load modifying factor for redundancy; LRFD 1.3.4)*

$\eta_I := 1.00$ *(load modifying factor for operational classification; LRFD 1.3.5)*

$(\eta_{strength})_{max} := \max\left(\eta_D \cdot \eta_R \cdot \eta_I, 0.95\right) = 1$ *(total load modification for loads for which a maximum of γ is appropriate for strength limit states; LRFD Eq. 1.3.2.1-2)*

$(\eta_{strength})_{min} := min\left(\frac{1}{\eta_D \cdot \eta_R \cdot \eta_I}, 1.0\right) = 1.00$ *(total load modification for loads for which a minimum of γ is appropriate for strength limit states; LRFD Eq. 1.3.2.1-3)*

Dynamic Load Allowance & Multiple Presence Factors

$IM := 1.33$ *(dynamic load allowance; LRFD Table 3.6.2.1-1)*

$$\gamma_{ADTT} := \begin{cases} 0.9 & \text{if } ADTT \le 100 \\ 0.95 & \text{else if } 100 \le ADTT \le 1000 \\ 1.0 & \text{else} \end{cases}$$ *(load reduction for low average daily truck traffic; LRFD C3.6.1.1.2)*

$\gamma_{ADTT} = 1$

$(m_1)_o := 1.2$ *(multiple presence factor for single lane loaded; LRFD Table 3.6.1.1.2-1)*

$(m_2)_o := 1.0$ *(multiple presence factor for two lanes loaded; LRFD Table 3.6.1.1.2-1)*

$(m_3)_o := 0.85$ *(multiple presence factor for three lanes loaded; LRFD Table 3.6.1.1.2-1)*

$(m_4)_o := 0.65$ *(multiple presence factor for four or more lanes loaded; LRFD Table 3.6.1.1.2-1)*

$m_1 := \gamma_{ADTT} \cdot (m_1)_o = 1.20$ *(multiple presence factor for single lane loaded adjusted for low ADTT)*

$m_2 := \gamma_{ADTT} \cdot (m_2)_o = 1.00$ *(multiple presence factor for two lanes loaded adjusted for low ADTT)*

$m_3 := \gamma_{ADTT} \cdot (m_3)_o = 0.85$ *(multiple presence factor for three lanes loaded adjusted for low ADTT)*

$m_4 := \gamma_{ADTT} \cdot (m_4)_o = 0.65$ *(multiple presence factor for three lanes loaded adjusted for low ADTT)*

$$N_i = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix} \qquad m_i = \begin{bmatrix} 1.2 \\ 1 \\ 0.85 \\ 0.65 \\ 0.65 \end{bmatrix} \qquad N_i m_i = \begin{bmatrix} 1.2 \\ 2 \\ 2.55 \\ 2.6 \\ 3.25 \end{bmatrix}$$

$g_{dist} := \max\left(N_i m_i\right) = 3.25$ *(distribution of traffic loads)*

DIMENSIONS

General Dimensions

General Bridge Dimensions:

$L_b := 160\ ft$ *(length of bridge)*

$L_1 := \frac{L_b}{3} = 53.3\ ft$ *(length of span 1)*

$L_2 := \frac{L_b}{3} = 53.3\ ft$ *(length of span 2)*

$L_3 := \frac{L_b}{3} = 53.3\ ft$ *(length of span 3)*

Roadway Dimensions:

$d_e := 2\ ft$ *(distance from the exterior girder to the interior edge of curb)*

$x_{WL} := 2\ ft$ *(distance from first wheel line to curb; LRFD 3.6.1.3.1)*

Deck Dimensions:

$b_{slab} := 76\ ft$ *(width of bridge deck slab)*

$(t_{slab})_{min} := 1\ ft + 6\ in$ *(minimum thickness of slab)*

$(t_{slab})_{max} := 2\ ft + 0\ in$ *(maximum thickness of slab)*

$t_{slab} := \frac{(t_{slab})_{min} + (t_{slab})_{max}}{2} = 21\ in$ *(average thickness of slab)*

Effective Strip Width (Edge Strip)

$E_2 := min\left(x_1 + 0.25 \cdot E_s + 12\ in, 0.5 \cdot E_s, 72\ in\right)$

$E_2 = 72\ in$ *(effective edge strip width - LRFD Eq. 4.6.2.1.4b)*

Lane Load Reduction for Edge Strip

LRFD Design Article 4.6.2.1.4b states that "edge beams shall be assumed to support one line of wheels and, where appropriate, a tributary portion of the design lane load." For this reason, the live load effects due to design truck loading will be reduced by 50% when determining the total live load effects for the edge strip in the calculations below. The live load effects due to design lane loading will be reduced in proportion to the width of lane load tributary to the edge strip.

$x_{trib} := \max\left(min\left(E_2 - x_1, 10\ ft\right), 0\ ft\right) = 0\ ft$ *(portion of design lane load tributary to the edge strip)*

$R_2 := \frac{x_{trib}}{10\ ft} = 0$ *(reduction factor for lane load tributary to edge strip)*

$(b_{eq})_{pos} := \left(26 + 6.6 \cdot S \cdot ft^{-1}\right) \cdot in = 31.5\ ft$ *(width of primary strip for positive flexure; LRFD Table 4.6.2.1.3-1)*

$(b_{eq})_{neg} := \left(48 + 3.0 \cdot S \cdot ft^{-1}\right) \cdot in = 17.33\ ft$ *(width of primary strip for negative flexure; LRFD Table 4.6.2.1.3-1)*

$b_{eq} := (b_{eq})_{pos} = 31.5\ ft$ *(controlling width of primary strip)*

LOAD EFFECTS

$(M_{DC})_{total} := 2922\ kip \cdot ft$ *(moment due to dead load, total cross-section)*

$M_{DC} := \left(\frac{(M_{DC})_{total}}{W}\right) \cdot b = 38.4\ kip \cdot ft$ *(moment due to dead load, effective width)*

$M_{DW} := 0\ kip \cdot ft$

$M_{LLL} := 165\ kip \cdot ft$

$M_{TLL} := 494\ kip \cdot ft$

$(M_{LL})_1 := \frac{\left(M_{TLL} \cdot IM + M_{LLL}\right) \cdot b}{E_1} = 59.6\ kip \cdot ft$ *(total live load moment at cross-section for interior strips)*

$(M_{LL})_2 := \frac{\left(50\% \cdot M_{TLL} \cdot IM + R_2 \cdot M_{LLL}\right) \cdot b}{E_2} = 54.8\ kip \cdot ft$ *(total live load moment at cross-section for edge strips)*

$M_{LL} := \max\left((M_{LL})_1, (M_{LL})_2\right) = 59.6\ kip \cdot ft$ *(controlling total live load moment at cross-section)*

$M_u := (\gamma_L)_{inv} \cdot M_{LL} + \gamma_{DC} \cdot M_{DC} + \gamma_{DW} \cdot M_{DW} = 152.4\ kip \cdot ft$ *(ultimate moment at cross-section)*

NOMINAL FLEXURAL RESISTANCE

Flexural Resistance

Stress Block Factors:

$$\beta_1 := \begin{cases} \text{if } f'_c < 4\ ksi \\ \quad 0.85 \\ \text{else} \\ \quad \max\left(0.85 - 0.05 \cdot \frac{\langle f'_c - 4\ ksi \rangle}{ksi}, 0.65\right) \end{cases}$$

(stress block factor; LRFD 5.6.2.2)

$\beta_1 = 0.80$

$$\alpha_1 := \begin{cases} \text{if } f'_c < 10\ ksi \\ \quad 0.85 \\ \text{else} \\ \quad \max\left(0.85 - 0.02 \cdot \frac{\langle f'_c - 10\ ksi \rangle}{ksi}, 0.75\right) \end{cases}$$

(stress block factor; LRFD 5.6.2.2)

$\alpha_1 = 0.85$

$c := \frac{A_s \cdot f_y}{\alpha_1 \cdot f'_c \cdot \beta_1 \cdot b} = 4.5\ in$

(distance between the neutral axis and the compressive face for rectangular behavior with bonded strands - LRFD Eq. 5.7.3.1.1-4)

$a := \beta_1 \cdot c = 3.6\ in$

(depth of equivalent stress block for rectangular section behavior with bonded strands)

$M_n := A_s \cdot f_y \cdot \left(d_s - \frac{a}{2}\right) = 206.4\ kip \cdot ft$

(nominal flexural resistance; LRFD 5.7.3.2.2 & 5.7.3.2.3)

Resistance Factor

$\varepsilon_t := \left(\frac{0.003}{c}\right) \cdot \langle d_s - c \rangle = 0.0073$

(net tensile strain; LRFD 5.6.2.1)

$\varepsilon_{cl} := 0.002$

(compression-controlled strain limit; LRFD 5.6.2.1)

$\varepsilon_{tl} := 0.005$

(tension-controlled strain limit; LRFD 5.6.2.1)

$\varphi_f := \max\left(min\left((\varphi_f)_c + \frac{0.15 \cdot \langle \varepsilon_t - \varepsilon_{cl} \rangle}{\langle \varepsilon_{tl} - \varepsilon_{cl} \rangle}, (\varphi_f)_t\right), (\varphi_f)_c\right)$

(flexural resistance factor prestressed members; LRFD Eq. 5.5.4.2-1)

$\varphi_f = 0.9$

$M_r := \varphi_f \cdot M_n = 186\ kip \cdot ft$

(flexural capacity)

$IC_f := \frac{M_u}{M_r} = 0.82$

$check_f := \left\| \begin{array}{l} \text{if } IC_f \le 1.0 \\ \quad \text{"okay"} \\ \text{else} \\ \quad \text{"no good"} \end{array} \right\|$

$check_f = \text{"okay"}$

Minimum Reinforcement

$M_{cr} = \gamma_3 \cdot \left(\left(\gamma_1 \cdot f_r + \gamma_2 \cdot f_{cpe} \right) \cdot S_c - M_{dnc} \cdot \left(\frac{S_c}{S_{nc}} - 1 \right) \right)$ *(cracking moment; LRFD Eq. 5.6.3.3.2-1)*

$S_c = S_{nc}$ ***therefore:*** $M_{dnc}(S_c/S_{nc} - 1) := 0 \ kip \cdot ft$

Minimum Reinforcement

$M_{cr} = \gamma_3 \cdot \left(\left(\gamma_1 \cdot f_r + \gamma_2 \cdot f_{cpe} \right) \cdot S_c - M_{dnc} \cdot \left(\frac{S_c}{S_{nc}} - 1 \right) \right)$ *(cracking moment; LRFD Eq. 5.6.3.3.2-1)*

$S_c = S_{nc}$ ***therefore:*** $M_{dnc}(S_c/S_{nc} - 1) := 0 \ kip \cdot ft$

$S_c := S_x$

$f_r := 0.24 \cdot \sqrt{f'_c \cdot ksi} = 0.5 \ ksi$ *(modulus of rupture; LRFD 5.4.2.6)*

$f_{cpe} := 0 \ ksi$ *(compressive stress in concrete due to effective prestress force)*

$\gamma_1 := 1.6$ *(flexural cracking variability factor)*

$\gamma_2 := 1.0$ *(prestress variability factor)*

$\gamma_3 := \frac{f_y}{f_u}$ *(ratio of specified minimum yield strength to ultimate strength)*

$M_{cr} := \overrightarrow{\gamma_3 \cdot \left(\left(\gamma_1 \cdot f_r + \gamma_2 \cdot f_{cpe} \right) \cdot S_c - M_{dnc}(S_c/S_{nc} - 1) \right)}$ *(cracking moment; LRFD Eq. 5.6.3.3.2-1)*

$check := \left\| \begin{array}{l} \text{if } M_r \ge min\left(1.33 \cdot M_u, M_{cr}\right) \\ \quad \text{"okay"} \\ \text{else} \\ \quad \text{"reduce Mn"} \end{array} \right\|$

$check = \text{"okay"}$

$$K := \begin{cases} \text{if } M_r \geq min\left(1.33 \cdot M_u, M_{cr}\right) \\ \quad 1.0 \\ \text{else} \\ \quad min\left(1.0, \dfrac{M_r}{min\left(1.33 \cdot M_u, M_{cr}\right)}\right) \end{cases}$$

(minimum reinforcement reduction factor - MBE 6A.5.6)

$K = 1.00$

RATING FACTORS: FLEXURE

$\gamma_{DC} = 1.25$ *(dead load factor for components and attachments)*

$\gamma_{DW} = 1.50$ *(dead load factor for wearing surface)*

$R_n := M_n$ *(nominal member resistance)*

$C := \varphi_c \cdot \varphi_s \cdot \varphi_f \cdot R_n = 186\ kip \cdot ft$ *(capacity, MBE Eqs. 6A.4.2.1-2 & 6A.4.2.1-3)*

$DC := M_{DC} = 38.4\ kip \cdot ft$ *(dead load effect due to structural components and attachments)*

$DW := M_{DW} = 0\ kip \cdot ft$ *(dead load effect due to wearing surface and utilities)*

$LL := M_{LL} = 59.6\ kip \cdot ft$ *(live load effect)*

$$RF_{inv} := \frac{C - \gamma_{DC} \cdot DC - \gamma_{DW} \cdot DW}{(\gamma_L)_{inv} \cdot LL}$$

(inventory design rating factor for positive flexure relative to the compression flange; MBE Eq. 6A.4.2.1-1)

$RF_{inv} = 1.32$

$$RF_{op} := \frac{(\gamma_L)_{inv}}{(\gamma_L)_{op}} \cdot RF_{inv}$$

(operating design rating factor for positive flexure)

$RF_{op} = 1.71$

GENERAL

Traffic Information

$ADT := 10000$ *(average daily traffic; assumed)*

$ADTT_{percent} := 10\%$ *(average daily truck traffic in percentage of ADT; assumed)*

$ADTT := (ADTT_{percent}) \cdot (ADT) = 1000$ *(average daily truck traffic)*

$v_{PSL} := 35\ mph$ *(posted speed limited)*

$v_{DSL} := 45\ mph$ *(design speed limited; assumed)*

$N_L := 4$ *(number of design lanes)*

$n_L := 2$ *(number lanes with traffic in the same direction)*

Material Properties

$\gamma_c := 150\ pcf$ *(unit weight of concrete)*

$\gamma_w := 62.4\ pcf$ *(unit weight of water)*

Hydraulic Properties

$Q_{US} := 18357\ cfs$ *(upstream flowrate; NWK H&H)*

$V_{US} := 10.3\ fps$ *(maximum upstream velocity; NWK H&H)*

Note: The flat face of the flood wall will have a drag coefficient similar to a square-ended pier.

$(C_D)_{flood.wall} := 1.4$ *(drag coefficient for square-ended pier; LRFD Table 3.7.3.1-1)*

$(C_D)_{pier} := 0.7$ *(drag coefficient for square-ended pier; LRFD Table 3.7.3.1-1)*

Wind Design Properties

$roughness :=$ ground surface roughness d *(ground surface roughness; LRFD 3.8.1.1.4)*

$wind.exposure :=$ wind exposure category d *(wind exposure category; LRFD 3.8.1.1.5)*

$V_{III} := 115\ mph$ *(design 3-second gust wind speed for Strength III; LRFD Table 3.8.1.1.2-1)*

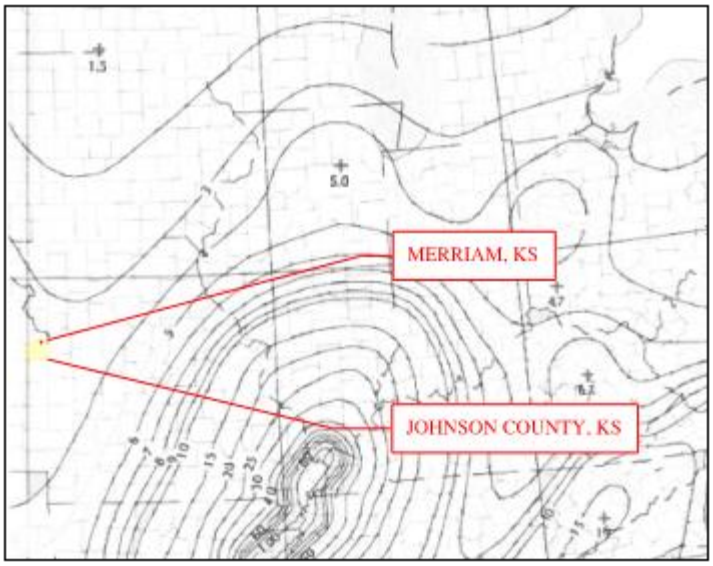
$G := 1.00$ *(gust effect factor; LRFD 3.8.1.2.1)*

$(C_D)_W := 1.3$ *(gust effect factor; LRFD Table 3.8.1.2.1-2)*

Seismic Design Properties

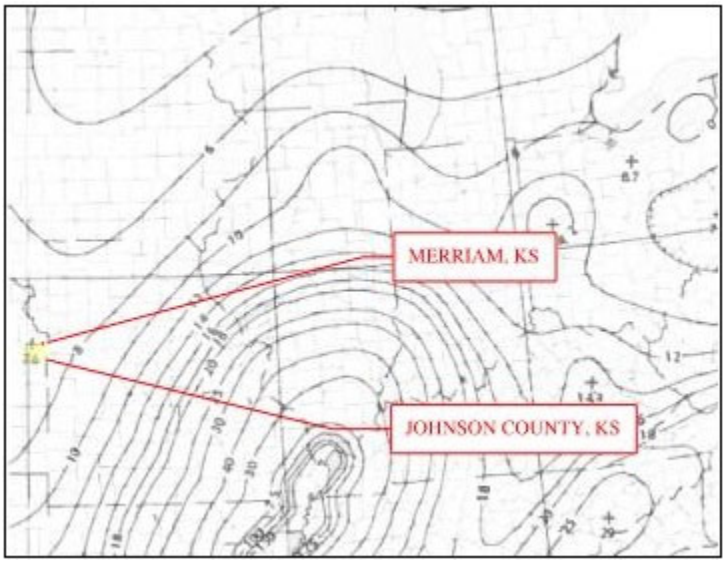
$site.class :=$ "d" *(site classification, assumed)*

LRFD Figure 3.10.2.1-1:



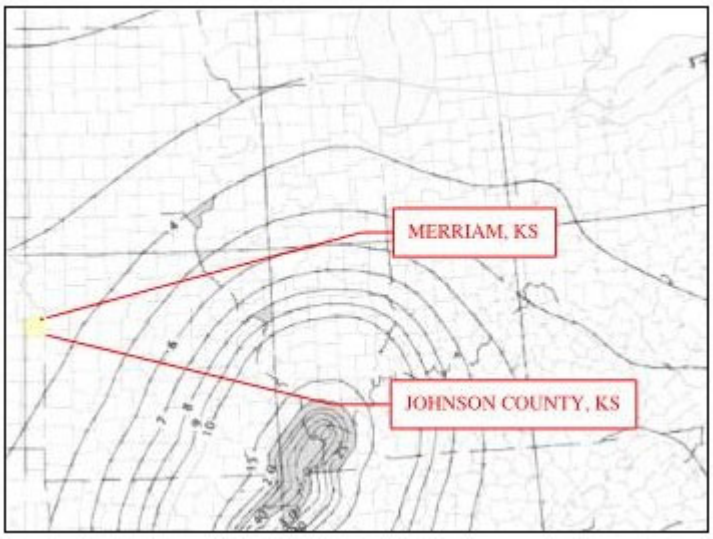
$PGA := 3.5\%$ *(peak seismic ground acceleration coefficient on rock; LRFD 9th Ed. Figure 3.10.2.1-1)*

LRFD Figure 3.10.2.1-2:



$S_S := 7.6\%$ *(horizontal response spectral acceleration coefficient at 0.2-s period on rock - site class b; LRFD 9th Ed. Figure 3.10.2.1-2)*

LRFD Figure 3.10.2.1-3:



$S_1 := 3.7\%$ *(horizontal response spectral acceleration coefficient at 1-s period on rock - site class b; LRFD 9th Ed. Figure 3.10.2.1-3)*

Load and Resistance Factors

Load Modifiers:

$\eta_D := 1.00$ *(load modifying factor for ductility; LRFD 1.3.3)*

$\eta_R := 1.00$ *(load modifying factor for redundancy; LRFD 1.3.4)*

$\eta_I := 1.00$ *(load modifying factor for operational classification; LRFD 1.3.5)*

$(\eta_{strength})_{max} := \max\left(\eta_D \cdot \eta_R \cdot \eta_I, 0.95\right) = 1$ *(total load modification for loads for which a maximum of γ is appropriate for strength limit states; LRFD Eq. 1.3.2.1-2)*

$(\eta_{strength})_{min} := min\left(\frac{1}{\eta_D \cdot \eta_R \cdot \eta_I}, 1.0\right) = 1.00$ *(total load modification for loads for which a minimum of γ is appropriate for strength limit states; LRFD Eq. 1.3.2.1-3)*

Dynamic Load Allowance & Multiple Presence Factors

$IM := 1.33$ *(dynamic load allowance; LRFD Table 3.6.2.1-1)*

$$\gamma_{ADTT} := \begin{cases} 0.9 & \text{if } ADTT \le 100 \\ 0.95 & \text{else if } 100 \le ADTT \le 1000 \\ 1.0 & \text{else} \end{cases}$$ *(load reduction for low average daily truck traffic; LRFD C3.6.1.1.2)*

$L_1 := min(L, 60\ ft) = 60\ ft$ *(modified span length)*

$W_{1.s} := min(W, 30\ ft) = 30\ ft$ *(modified edge-to-edge width for single-lane loading)*

$W_{1.m} := min(W, 60\ ft) = 60\ ft$ *(modified edge-to-edge width for multilane loading)*

Effective Strip Width (Interior Strip)

$E_s := \left(10 + 5 \cdot \sqrt{L_1 \cdot W_{1.s} \cdot ft^{-2}}\right) \cdot in = 222\ in$ *(equivalent width for single-lane loading; LRFD Eq. 4.6.2.3-1)*

$E_m := min\left(\left(84 + 1.44 \cdot \sqrt{L_1 \cdot W_{1.m} \cdot ft^{-2}}\right) \cdot in, \frac{12 \cdot W}{N_L}\right) = 170\ in$ *(equivalent width for multilane loading; LRFD Eq. 4.6.2.3-2)*

$E_1 := min(E_s, E_m) = 170\ in$ *(effective strip width for interior strips)*

Effective Strip Width (Edge Strip)

$E_2 := min(x_1 + 0.25 \cdot E_s + 12\ in, 0.5 \cdot E_s, 72\ in)$

$E_2 = 72\ in$ *(effective edge strip width - LRFD Eq. 4.6.2.1.4b)*

Lane Load Reduction for Edge Strip

LRFD Design Article 4.6.2.1.4b states that "edge beams shall be assumed to support one line of wheels and, where appropriate, a tributary portion of the design lane load." For this reason, the live load effects due to design truck loading will be reduced by 50% when determining the total live load effects for the edge strip in the calculations below. The live load effects due to design lane loading will be reduced in proportion to the width of lane load tributary to the edge strip.

$x_{trib} := \max\left(min\left(E_2 - x_1, 10\ ft\right), 0\ ft\right) = 0\ ft$ *(portion of design lane load tributary to the edge strip)*

$R_2 := \frac{x_{trib}}{10\ ft} = 0$ *(reduction factor for lane load tributary to edge strip)*

$(b_{eq})_{pos} := \left(26 + 6.6 \cdot S \cdot ft^{-1}\right) \cdot in = 35.17\ ft$ *(width of primary strip for positive flexure; LRFD Table 4.6.2.1.3-1)*

$(b_{eq})_{neg} := \left(48 + 3.0 \cdot S \cdot ft^{-1}\right) \cdot in = 19\ ft$ *(width of primary strip for negative flexure; LRFD Table 4.6.2.1.3-1)*

$b_{eq} := (b_{eq})_{pos} = 35.17\ ft$ *(controlling width of primary strip)*

LOAD EFFECTS

$(M_{DC})_{total} := 3708\ kip \cdot ft$ *(moment due to dead load, total cross-section)*

$M_{DC} := \left(\frac{(M_{DC})_{total}}{W}\right) \cdot b = 53\ kip \cdot ft$ *(moment due to dead load, effective width)*

$M_{DW} := 0\ kip \cdot ft$

$M_{LLL} := 212\ kip \cdot ft$

$M_{TLL} := 585\ kip \cdot ft$

$(M_{LL})_1 := \frac{\left(M_{TLL} \cdot IM + M_{LLL}\right) \cdot b}{E_1} = 69.7\ kip \cdot ft$ *(total live load moment at cross-section for interior strips)*

$(M_{LL})_2 := \frac{\left(50\% \cdot M_{TLL} \cdot IM + R_2 \cdot M_{LLL}\right) \cdot b}{E_2} = 64.8\ kip \cdot ft$ *(total live load moment at cross-section for edge strips)*

$M_{LL} := \max\left((M_{LL})_1, (M_{LL})_2\right) = 69.7\ kip \cdot ft$ *(controlling total live load moment at cross-section)*

$M_u := (\gamma_L)_{inv} \cdot M_{LL} + \gamma_{DC} \cdot M_{DC} + \gamma_{DW} \cdot M_{DW} = 188.2\ kip \cdot ft$ *(ultimate moment at cross-section)*

NOMINAL FLEXURAL RESISTANCE

Flexural Resistance

Stress Block Factors:

$$\beta_1 := \begin{cases} \text{if } f'_c < 4\ ksi \\ \quad 0.85 \\ \text{else} \\ \quad \max\left(0.85 - 0.05 \cdot \frac{\langle f'_c - 4\ ksi \rangle}{ksi}, 0.65\right) \end{cases}$$

(stress block factor; LRFD 5.6.2.2)

$\beta_1 = 0.80$

$$\alpha_1 := \begin{cases} \text{if } f'_c < 10\ ksi \\ \quad 0.85 \\ \text{else} \\ \quad \max\left(0.85 - 0.02 \cdot \frac{\langle f'_c - 10\ ksi \rangle}{ksi}, 0.75\right) \end{cases}$$

(stress block factor; LRFD 5.6.2.2)

$\alpha_1 = 0.85$

$c := \frac{A_s \cdot f_y}{\alpha_1 \cdot f'_c \cdot \beta_1 \cdot b} = 4.7\ in$

(distance between the neutral axis and the compressive face for rectangular behavior with bonded strands - LRFD Eq. 5.7.3.1.1-4)

$a := \beta_1 \cdot c = 3.8\ in$

(depth of equivalent stress block for rectangular section behavior with bonded strands)

$M_n := A_s \cdot f_y \cdot \left(d_s - \frac{a}{2}\right) = 215.7\ kip \cdot ft$

(nominal flexural resistance; LRFD 5.7.3.2.2 & 5.7.3.2.3)

Resistance Factor

$\varepsilon_t := \left(\frac{0.003}{c}\right) \cdot \langle d_s - c \rangle = 0.0068$

(net tensile strain; LRFD 5.6.2.1)

$\varepsilon_{cl} := 0.002$

(compression-controlled strain limit; LRFD 5.6.2.1)

$\varepsilon_{tl} := 0.005$

(tension-controlled strain limit; LRFD 5.6.2.1)

$\varphi_f := \max\left(min\left((\varphi_f)_c + \frac{0.15 \cdot \langle \varepsilon_t - \varepsilon_{cl} \rangle}{\langle \varepsilon_{tl} - \varepsilon_{cl} \rangle}, (\varphi_f)_t\right), (\varphi_f)_c\right)$

(flexural resistance factor prestressed members; LRFD Eq. 5.5.4.2-1)

$\varphi_f = 0.9$

$M_r := \varphi_f \cdot M_n = 194\ kip \cdot ft$

(flexural capacity)

$IC_f := \frac{M_u}{M_r} = 0.97$

$check_f := \begin{cases} \text{if } IC_f \le 1.0 \\ \quad \text{"okay"} \\ \text{else} \\ \quad \text{"no good"} \end{cases}$

$check_f = \text{"okay"}$

Minimum Reinforcement

$M_{cr} = \gamma_3 \cdot \left(\left(\gamma_1 \cdot f_r + \gamma_2 \cdot f_{cpe} \right) \cdot S_c - M_{dnc} \cdot \left(\frac{S_c}{S_{nc}} - 1 \right) \right)$ *(cracking moment; LRFD Eq. 5.6.3.3.2-1)*

$S_c = S_{nc}$ ***therefore:*** $M_{dnc}(S_c/S_{nc} - 1) := 0 \; kip \cdot ft$

Minimum Reinforcement

$M_{cr} = \gamma_3 \cdot \left(\left(\gamma_1 \cdot f_r + \gamma_2 \cdot f_{cpe} \right) \cdot S_c - M_{dnc} \cdot \left(\frac{S_c}{S_{nc}} - 1 \right) \right)$ *(cracking moment; LRFD Eq. 5.6.3.3.2-1)*

$S_c = S_{nc}$ ***therefore:*** $M_{dnc}(S_c/S_{nc} - 1) := 0 \; kip \cdot ft$

$S_c := S_x$

$f_r := 0.24 \cdot \sqrt{f'_c \cdot ksi} = 0.5 \; ksi$ *(modulus of rupture; LRFD 5.4.2.6)*

$f_{cpe} := 0 \; ksi$ *(compressive stress in concrete due to effective prestress force)*

$\gamma_1 := 1.6$ *(flexural cracking variability factor)*

$\gamma_2 := 1.0$ *(prestress variability factor)*

$\gamma_3 := \frac{f_y}{f_u}$ *(ratio of specified minimum yield strength to ultimate strength)*

$M_{cr} := \overrightarrow{\gamma_3 \cdot \left(\left(\gamma_1 \cdot f_r + \gamma_2 \cdot f_{cpe} \right) \cdot S_c - M_{dnc}(S_c/S_{nc} - 1) \right)}$ *(cracking moment; LRFD Eq. 5.6.3.3.2-1)*

$check := \begin{cases} \text{if } M_r \ge min\left(1.33 \cdot M_u, M_{cr}\right) \\ \quad \text{"okay"} \\ \text{else} \\ \quad \text{"reduce Mn"} \end{cases}$

$check = \text{"okay"}$

$$K := \left\| \begin{array}{l} \text{if } M_r \geq min\left(1.33 \cdot M_u, M_{cr}\right) \\ \quad \| \ 1.0 \\ \text{else} \\ \quad \| \ min\left(1.0, \frac{M_r}{min\left(1.33 \cdot M_u, M_{cr}\right)}\right) \end{array} \right\|$$

(minimum reinforcement reduction factor - MBE 6A.5.6)

$K = 1.00$

RATING FACTORS: FLEXURE

$\gamma_{DC} = 1.25$ *(dead load factor for components and attachments)*

$\gamma_{DW} = 1.50$ *(dead load factor for wearing surface)*

$R_n := M_n$ *(nominal member resistance)*

$C := \varphi_c \cdot \varphi_s \cdot \varphi_f \cdot R_n = 194 \ kip \cdot ft$ *(capacity, MBE Eqs. 6A.4.2.1-2 & 6A.4.2.1-3)*

$DC := M_{DC} = 53 \ kip \cdot ft$ *(dead load effect due to structural components and attachments)*

$DW := M_{DW} = 0 \ kip \cdot ft$ *(dead load effect due to wearing surface and utilities)*

$LL := M_{LL} = 69.7 \ kip \cdot ft$ *(live load effect)*

$$RF_{inv} := \frac{C - \gamma_{DC} \cdot DC - \gamma_{DW} \cdot DW}{(\gamma_L)_{inv} \cdot LL}$$

(inventory design rating factor for positive flexure relative to the compression flange; MBE Eq. 6A.4.2.1-1)

$RF_{inv} = 1.05$

$$RF_{op} := \frac{(\gamma_L)_{inv}}{(\gamma_L)_{op}} \cdot RF_{inv}$$

(operating design rating factor for positive flexure)

$RF_{op} = 1.36$

Sensitivity Analysis

E.1 SUPPLEMENTAL H&H REPORT

E.1.1. Introduction

The purpose of this supplemental report is to provide detailed methodology behind the hydrologic and hydraulic model development and analyses, along with background information of the project area.

E.1.2. Flood History

Major floods on Turkey Creek are usually caused by short-duration, high-intensity storms following an extended period of general rainfall over the basin. The rainfall preceding the heavy rains saturates the soil, preventing further infiltration and producing runoff into the Turkey Creek channel, creating higher than average flow. Since the Turkey Creek channel is so narrow and urbanized, it is usually subject to flash flood events, which are difficult to forecast and prepare for. Earlier flood events on Turkey Creek are known to have happened in 1844, 1951, 1958, 1961, and 1968. Very little information was documented for these specific events. Recent flood events that have available records and documentation include 1977, 1983, 1986, 1993, 1995, 1996, 1998, and 2017. However, the focus will be on the four largest flood events, which were 1977, 1993, 1998, and 2017. The first three floods' rainfall data were recorded by the same rain gage at Shawnee, Kansas. Precipitation for the 2017 events were determined using both Johnson County Stormwatch rain gage data and National Weather Service (NWS) radar observations. A basin average is provided for 21–22 August 2017. Table E.6 summarizes the observed precipitation events. Subsections E.1.2.1 through E.1.2.9 discuss details pertaining to historic flood events.

Table E.1. Comparison of Rainfall Totals for Major Turkey Creek Floods

Flood Event Date	Peak Hour Rainfall (inches)	Total Rainfall (inches)	Recorded Dates
1977	1.60	10.90	12–13 September 1977
1993	1.50	6.00	10 July 1993
1998	3.81	4.44	04 October 1998
2017	1.05	5.71	21–22 August 2017
2025	3.83	5.5	16-17 July 2025

E.1.2.1. Flood of 1935

The greatest known flood at Merriam, KS at the time occurred in June 1935 with an estimated Turkey Creek discharge of 13,650 cfs. It should be noted that a specific location of estimated flow was not given in the historic documentation, but it is assumed that flow was estimated at Johnson Dr. in Merriam, KS. This flood inundated the city area to depths of 7 feet above what was considered flood stage at the time. Development in the area was not extensive in 1935 and no estimated damage caused by this flood is available.

E.1.2.2. Flood of 1944

The April 1944 flood at Merriam, KS had an estimated Turkey Creek discharge of 11,300 cfs. It inundated the city to depths of about 6 feet above what was considered flood stage at the time. 58 residences and businesses were affected, and the damage was estimated at $118,700 in 1944 price levels.

E.1.2.3. Flood of 1958

In July 1958, a flood with an estimated discharge of 4,400 cfs inundated a total of 69 residences and business establishments and resulted in damages estimated at $155,000 in 1958 price levels.

E.1.2.4. Flood of 1961

The September 1961 flood at Merriam had an estimated discharge of 4,700 cfs and inundated a total of 82 residences and business establishments. An exhaustive damage survey, conducted shortly after the flood, established a value of $257,000 (1961 price levels) in damages in the city, of which $240,000 occurred along the main stem of Turkey Creek. This survey included all flood damages within the corporate city limits. The previous flood damage estimates may have included a smaller area, but the primary reason for the increasing damage values is the rapid development of the flood plain at the time.

E.1.2.5. Flood of 1977

Locally known as the Plaza Flood, this was a flash flood event that occurred 12–13 September 1977, throughout the Kansas City metropolitan area. It was caused by a high intensity storm following a long period of light rain. Approximately 16 inches of rain fell over the Kansas City, Missouri, area over the course of the event.

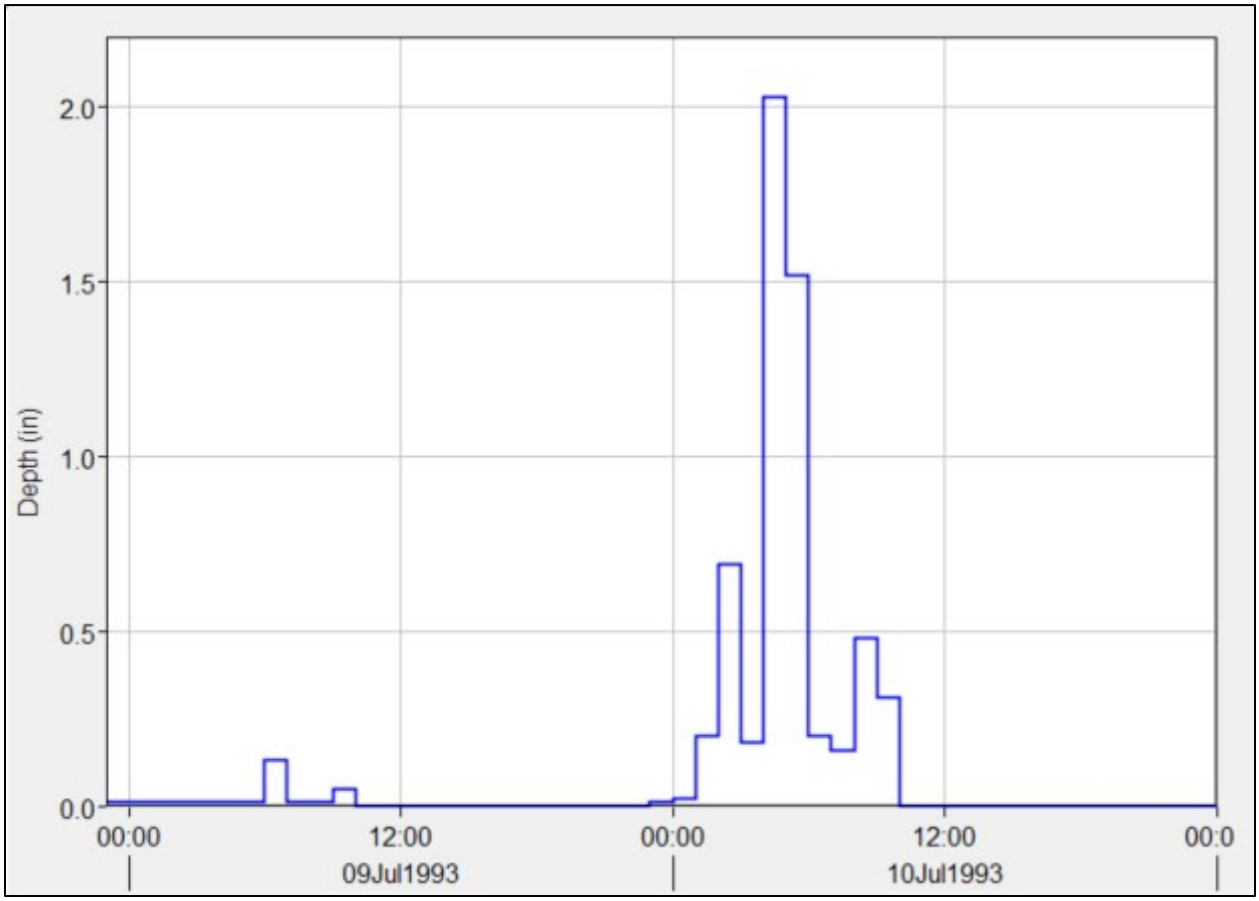
Most of the focus was on Brush Creek, which travels through the Plaza and discharges into the Blue River. During this event, there were 25 fatalities and 1,000 automobiles totaled, along with millions of dollars in damages to the commercial and residential areas surrounding Brush Creek.

In the Turkey Creek area, $8.1 million (1977 price levels) in damages occurred from flooding. Although damages were extensive, the urban study conducted after the flood determined implementing a program for managing flood events along Turkey Creek was not feasible.

E.1.2.6. Flood of 1993

Extensive flooding occurred on 10 July 1993. Although this year was also a major flood year for the Missouri and Kansas Rivers in Kansas City, this was an unrelated flash flood event caused by high intensity storms on that date. When Turkey Creek flooded in 1993, it overtopped I-35 at five different locations. The flooding occurring during this event caused one fatality. Damages from the 1993 event were estimate at $3.4 million in Merriam, Kansas, and $20 million in the lower basin in 1993 price levels. A rainfall gage located at the Overland Park City Hall building (approximately 3.3 miles south of Merriam, Kansas) recorded the July 1993 storm event. Figure E.1 provides a rainfall hyetograph of the event. According to this observed data, approximately 5.8 inches of rain fell over the upper portion of the Turkey Creek watershed within a 12-hour period.

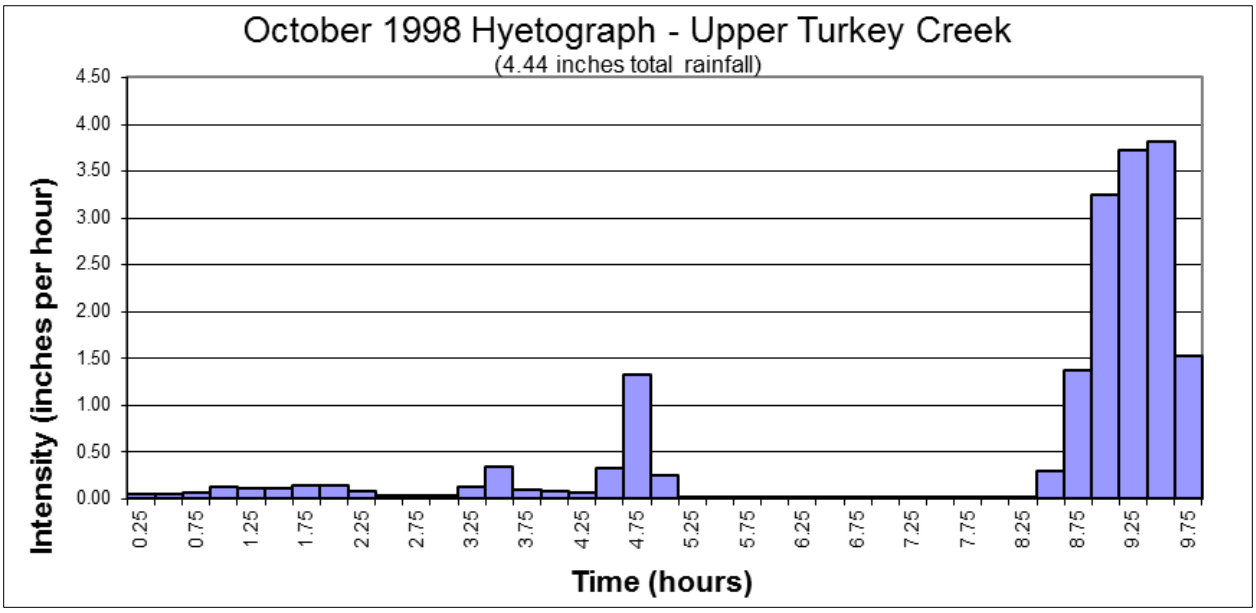
Figure E.1. 10 July 1993 Rainfall Hyetograph for Overland Park, Kansas City Hall Rain Gage.



E.1.2.7. Flood of 1998

The maximum flood of record for Turkey Creek occurred in October 1998 and resulted from the combined effects of saturated soil due to rain on 6 out of 7 days in one week and a high intensity storm that started 4 October 1998. The storm covered the Kansas City metropolitan area with rain for the entire day with afternoon rainfall totals of 0.25 to 1.00 inches. Around 7:00 p.m., another round of storms produced an additional 3 to 5 inches of rain in a 2-hour period. The rainfall produced by this event exceeded the rainfall amount defined as the 1% AEP (1/100-year event) at the time. Although this flood had the least amount of total rainfall when compared to the 1977 and 1993 floods, it produced the highest amount of rainfall in the peak hour. Figure E.2 illustrates the 10 hours of highest rainfall intensity of the 1998 rainfall event hyetograph emphasizing the rapidness of this event. The worst damages caused by this flood occurred at Merriam, Kansas, near the midpoint of the Upper Turkey Creek reach. Multiple bridges and roadways were flooded during this event including I-35 and the BNSF railroad tracks south of 75th Street. The total cost of damages was estimated at $12 million in Merriam, Kansas, and $20 million in the lower basin area, in 1998 price levels.

Figure E.2. Hyetograph of 4 October 1998 Storm Event

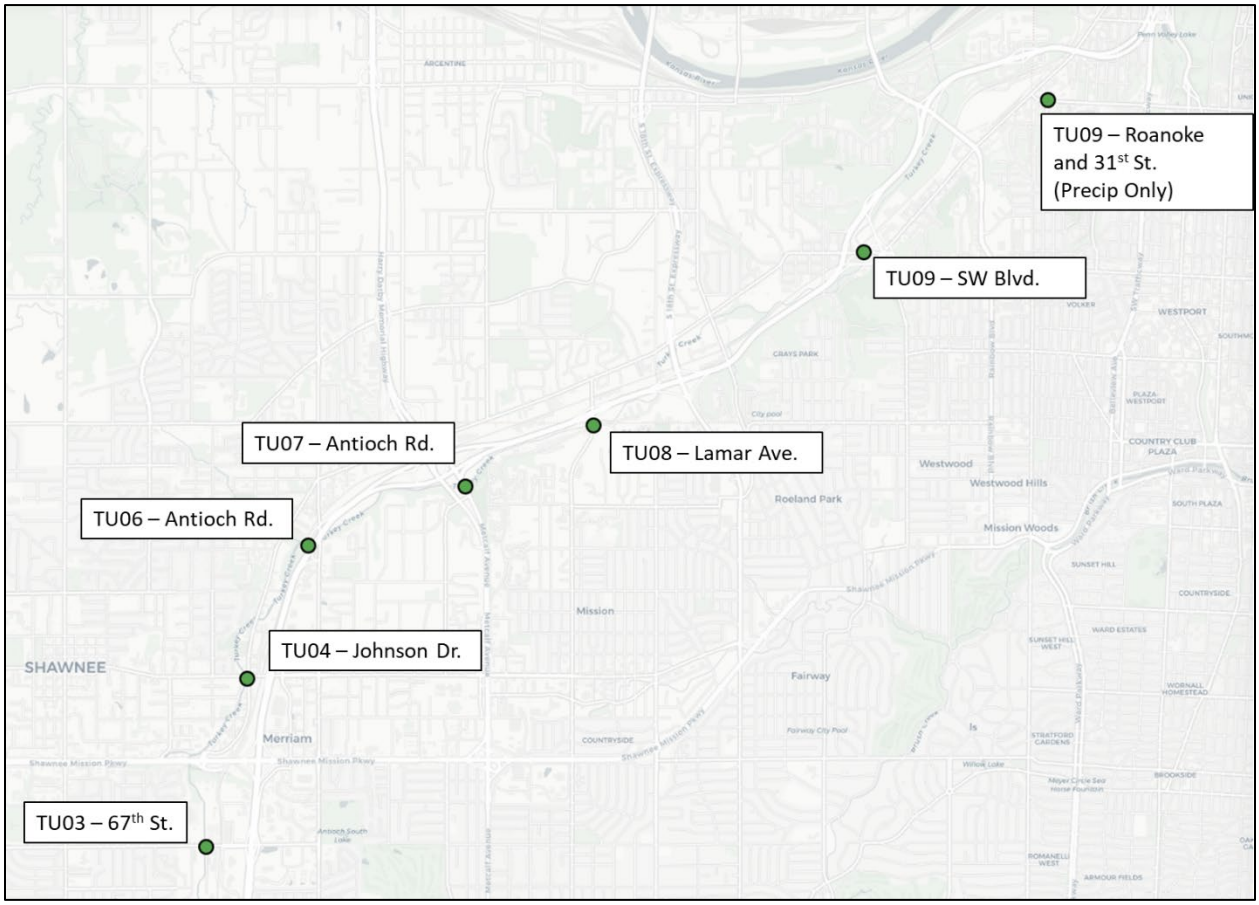


E.1.2.8. Floods of 2017

Three significant rainfall events occurred in the Turkey Creek watershed during the summer of 2017 on 26–27 July, 5–6 August, and 21–22 August. Storm total precipitation was highest on 21–22 August, but the intensity was greater for 26–27 July and 5–6 August. Rainfall from the events produced some of the highest stages along Turkey Creek since the flood of record on 4 October 1998. Of the 2017 events, 26–27 July resulted in the record stage of 16.45 feet at the Johnson Drive gage.

Precipitation, flow rate, and stream stage from the 2017 events were compared to historical records and to published data. Precipitation totals for the 2017 events were determined using both Johnson County Stormwatch rain gage data and NWS radar observations. The rain gages were location along Turkey Creek at Johnson Drive, Southwest Boulevard, and Lamar Avenue. Average basin precipitation totals were estimated from the NWS radar data using the Meteorological Visualization Utility Engine (MetVUE) software. Figure E.3 provides locations of the Stormwatch gages along Turkey Creek. All gages record both river stage and rainfall, with the exception of TU09, which records rainfall only.

Figure E.3. Turkey Creek Stormwatch Gages



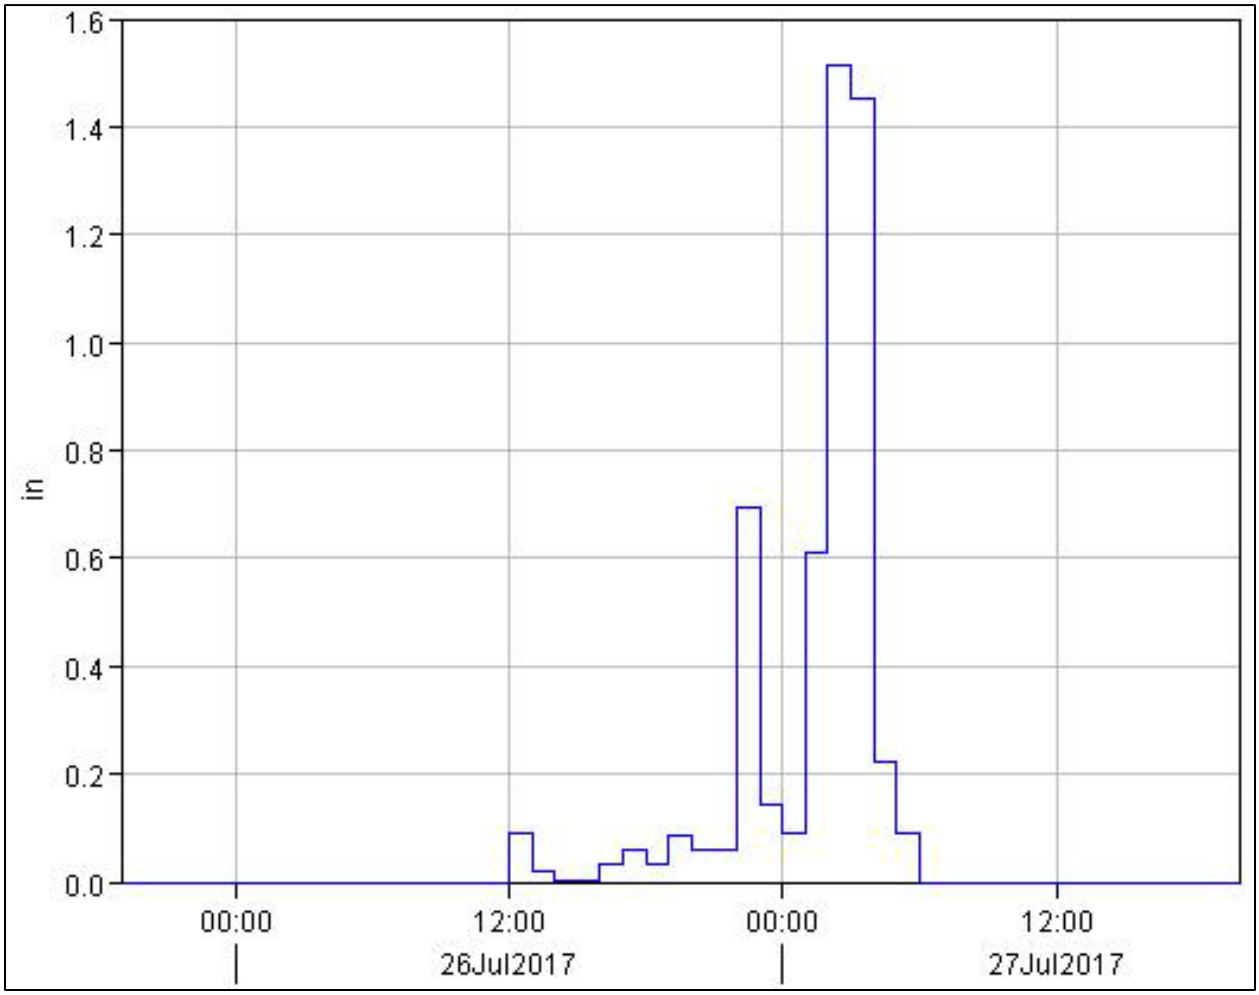
E.1.2.1.1 26–27 July 2017

An average of 5.27 inches of rain fell over the Turkey Creek Basin between 12:00 p.m. on 26 July 2017, and 6:00 a.m. on 27 July 2017. Approximately 68 percent of this total fell in a three-hour period between 1:00 and 4:00 a.m. on the 27th; while the maximum hourly total was 1.52 inches, occurring between 2:00 and 3:00 p.m. on the 27th. Table E.2 shows precipitation totals for the gages and the basin. All the rain gages recorded higher totals and more intense rainfall than the basin average. Figure E.4 shows the basin average hyetograph.

Table E.2. Precipitation Totals for 26–27 July 2017

Location	Total (inches)	Maximum 1-hour (inches)	Maximum 3-hour (inches)	Maximum 6-hour (inches)
Southwest Boulevard	5.92	1.80	4.12	5.32
Lamar Avenue	5.24	1.76	3.96	4.80
Johnson Drive	5.56	2.16	4.28	5.20
Basin Average	5.27	1.52	3.58	4.51

Figure E.4. Turkey Creek Basin Average Hyetograph for 26–27 July 2017



E.1.2.1.1 5–6 August 2017

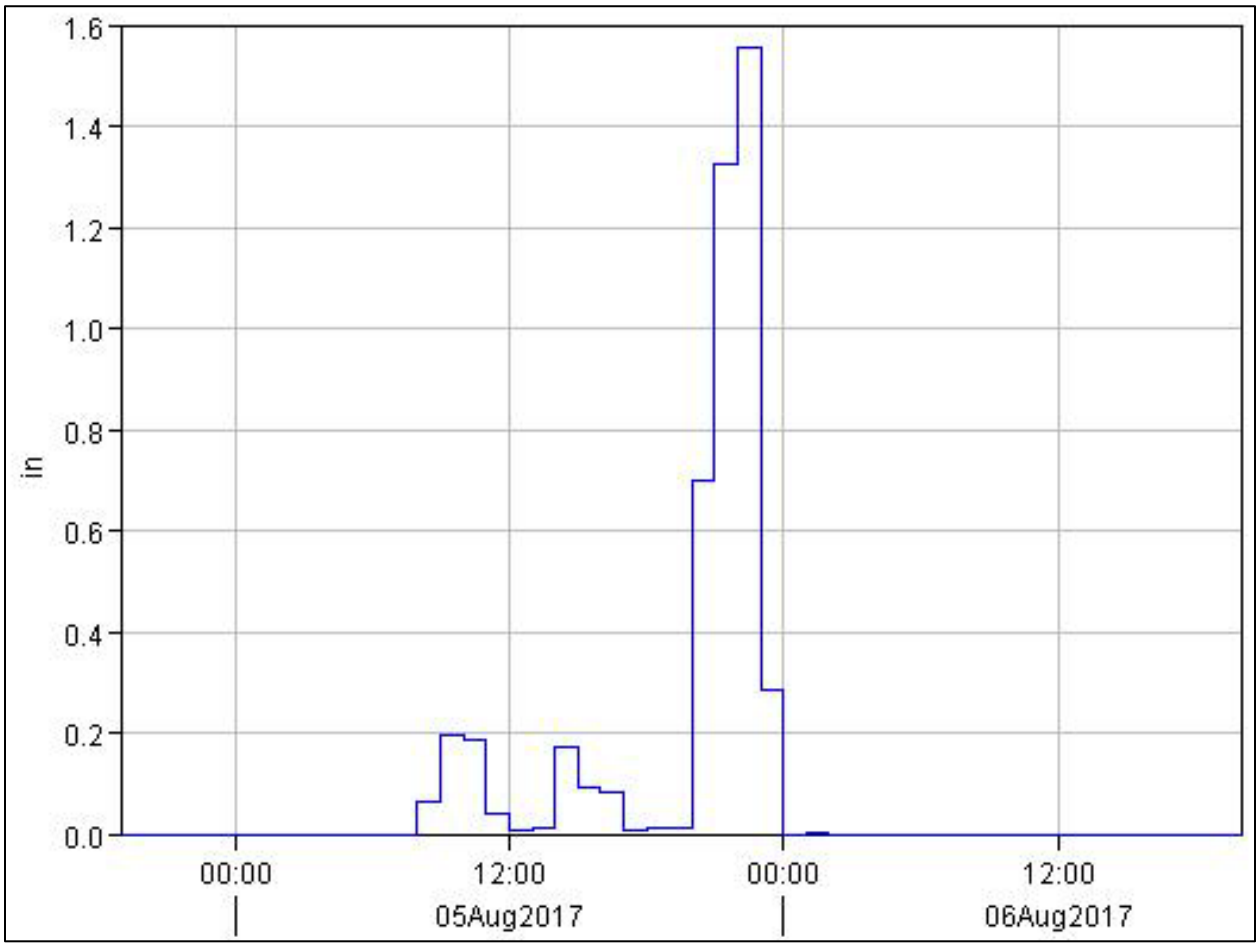
A total of 4.75 inches of rain fell over the Turkey Creek Basin between 8:00 a.m. 5 August 2017, and 2:00 a.m. 6 August 2017. Approximately 75 percent of the total precipitation fell in a three-hour period between 8:00 p.m. and 11:00 p.m. on the 5th; while the maximum 1-hour intensity was 1.55 inches between 10:00 p.m. and 11:00 p.m. Table E.3 shows storm precipitation totals for the gages and the entire basin. The rainfall totals were significantly higher at the Lamar Avenue and Johnson Drive gages than the basin average and the Southwest Boulevard gage. Peak discharge was estimated using the USACE lower Turkey Creek design model at Johnson Drive and Southwest Boulevard in the Turkey Creek 2017 flood report. Figure E.5 shows the basin average hyetograph.

Table E.3. Precipitation Totals for 5–6 August 2017

Location	Total (inches)	Maximum 1-hour (inches)	Maximum 3-hour (inches)	Maximum 6-hour (inches)	Peak Discharge (cfs)*
Southwest Boulevard	4.72	1.48	3.64	4.04	7,130
Lamar Avenue	6.32	2.24	4.48	5.20	—
Johnson Drive	6.12	2.68	5.20	5.40	13,400
Basin Average	4.75	1.55	3.58	3.89	—

*Note: Peak discharges estimated using RAS rating curves from lower Turkey Creek design model

Figure E.5. Turkey Creek Basin Average Hyetograph for 5–6 August 2017



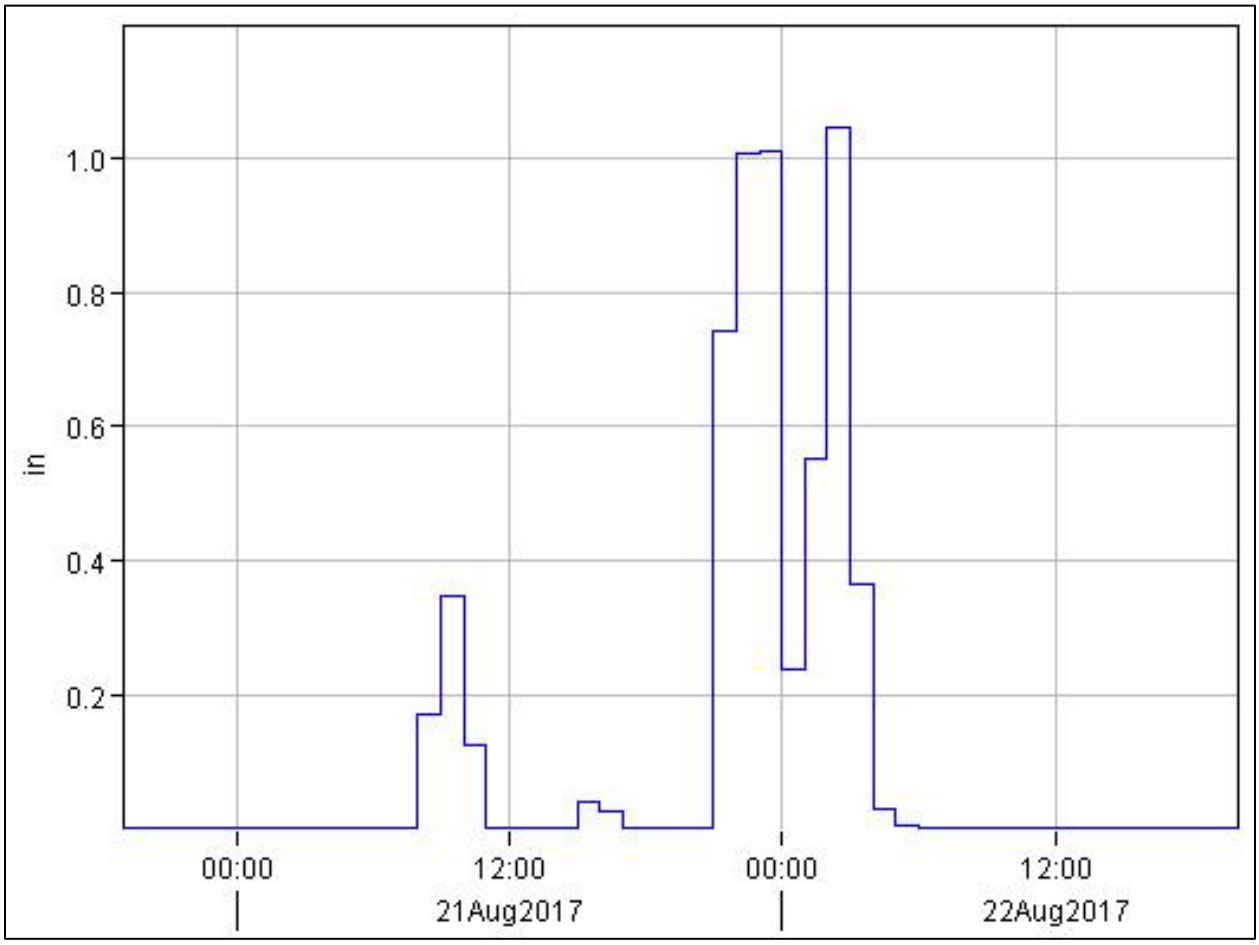
E.1.2.1.1 21–22 August 2017

The total basin precipitation for 21–22 August 2017, was 5.71 inches, and occurred between 8:00 a.m. on the 21st and 6:00 a.m. on the 22nd. The maximum hourly total was 1.05 inches between 2:00 and 3:00 a.m. on the 21st, and the maximum three-hour total was 2.76 inches between 1:00 and 4:00 a.m. on the 21st. Table E.4 contains the gage and basin rainfall totals for the event and indicates that the Southwest Boulevard gage recorded the greatest amounts. Figure E.6 shows the hyetograph for the basin.

Table E.4. Precipitation Totals for 21–22 August 2017

Location	Total (inches)	Maximum 1-hour (inches)	Maximum 3-hour (inches)	Maximum 6-hour (inches)
Southwest Boulevard	6.24	1.40	3.16	5.32
Lamar Avenue	5.24	1.08	2.72	4.64
Johnson Drive	4.96	1.08	2.84	4.56
Basin Average	5.71	1.05	2.76	4.60

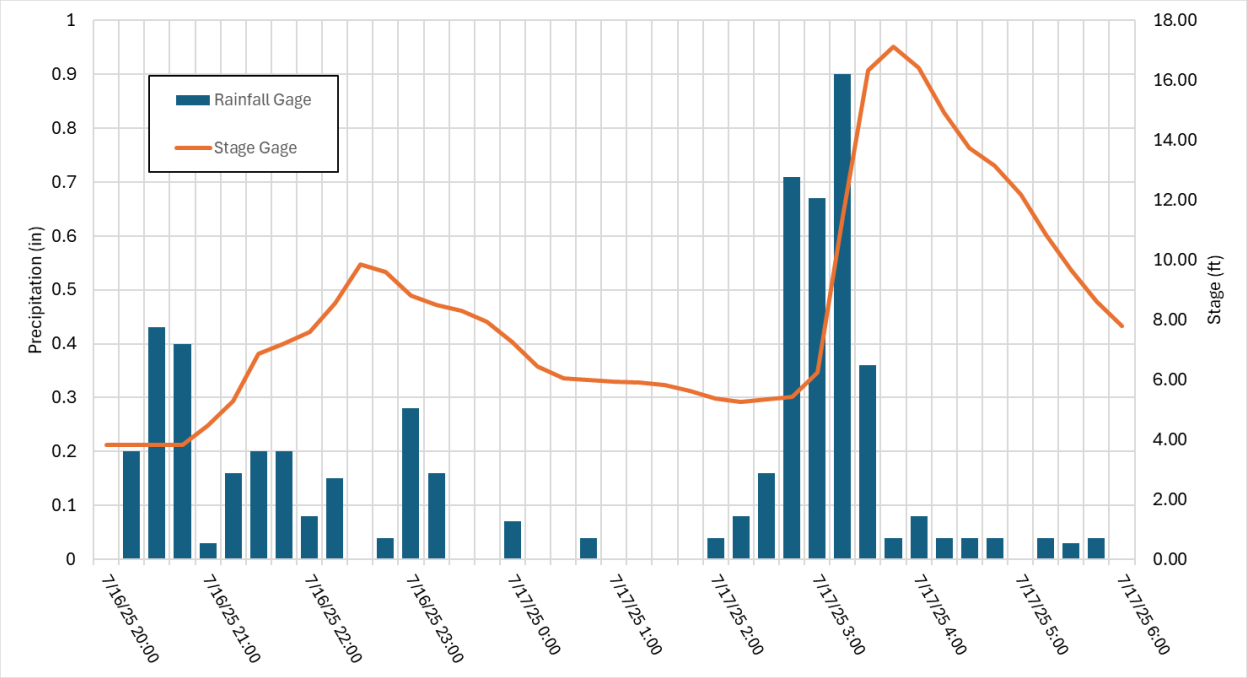
Figure E.6. Turkey Creek Basin Average Hyetograph for 21–22 August 2017



E.1.2.9. Flood of 2025

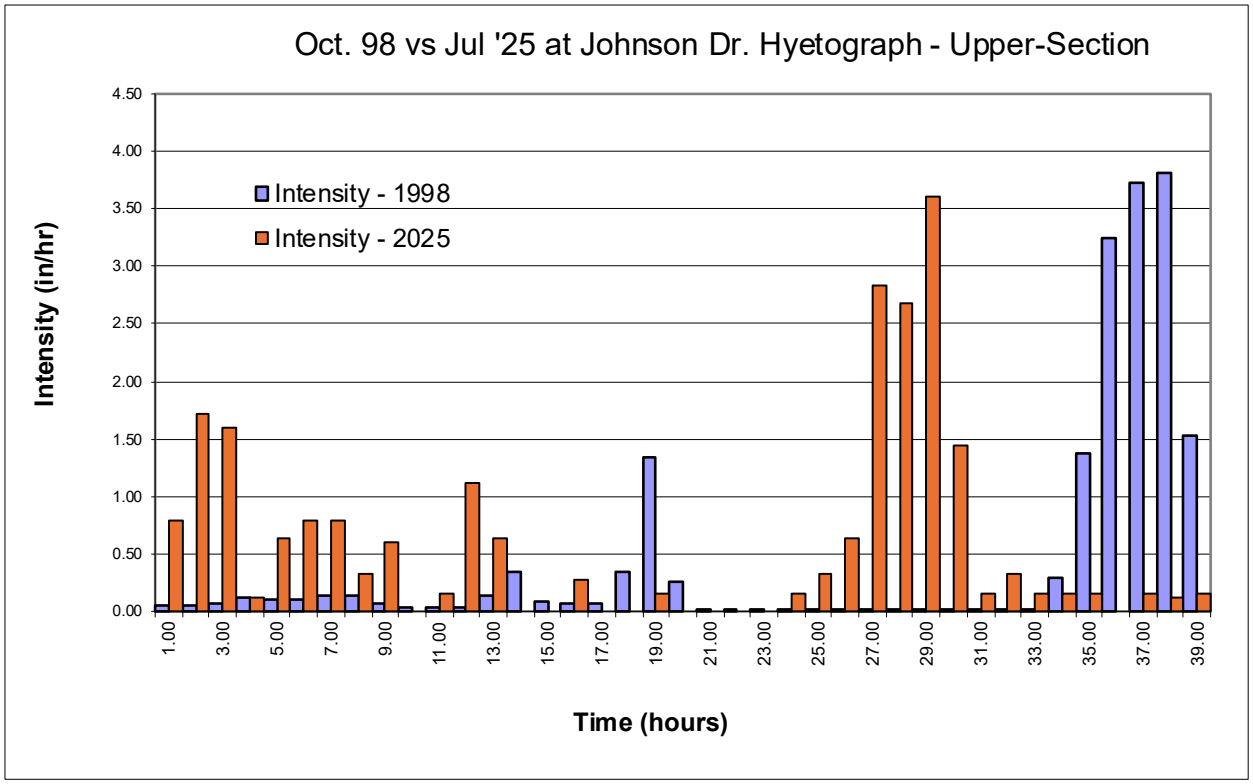
During the overnight hours of 16-17 July 2025, a storm event occurred in the Kansas City metro, including the Turkey Creek watershed. This event produced an average total rainfall of approximately 5.5 inches on the basin upstream of the project area in about 10 hours. Figure E.7 below overlays the rainfall hyetograph (at Johnson Drive StormWatch Gage TU04) with the Turkey Creek stage at the same location. This storm event produced a record gage stage of 17.24 feet at Johnson Drive within the gage's period of record (Sep1999-Present) and is second to only the 1998 flood event which occurred prior to the gage's installation.

Figure E.7. July 2025 Rainfall Hyetograph and Stage Hydrograph at Johnson Drive StormWatch Gage (TU04).



This event was quite similar to the 1998 storm in terms of total rainfall and total storm duration. Both events had lighter rainfall to start saturating the ground followed by an intense 1-2 hour burst of rainfall that drove the flooding. This is readily apparent in the previous figure which shows the very short lag time between peak rainfall intensity and peak stage. Figure E.8 provides a comparison of the rainfall hyetographs between the 1998 and 2025 storm events. Both events produced a maximum 15-min rainfall intensity of 3.8 in/hr, though the 1998 event had slightly more volume in this peak period. Based on Atlas 14 precipitation-frequency-duration tables, the 2025 event plots between a 4% AEP (1/25-year) and 2% AEP (1/50-year) storm event.

Figure E.8. Rainfall Hyetograph Comparison – 1998 vs. 2025



Despite the 1998 event producing 1.1 inches less of total rainfall, highwater marks showed a peak stage approximately 7 feet higher than the 2025 event. Figure E.9 provides a summary of the 2025 event surveyed highwater marks and their locations These were collected the following week on 24 July 2026. Information regarding the collection of the high water marks can be found in the high water mark document referenced in Section 4. The substantial difference in stage could be due to poor channel conditions in 1998 and potentially a lower conveyance capacity from the previous Johnson Drive bridge. The bridge was replaced around 2013-2014, by the Kansas Department of Transportation. Details of the previous bridge were not found, so there is uncertainty of the previous bridge played a role in producing higher stages during the 1998 event. Cursory review of aerial imagery from the late 1990s and early 2000s revealed that Turkey Creek channel was significantly overgrown. The channel had since been cleared of overgrown vegetation which notably improves channel capacity.

Figure E.9. July 2025 Surveyed Highwater Marks.

HWM #	Location	Elev (feet, NAVD88)	Notes
1	Quail Creek Park	956.75	Tributary to Turkey Creek
2	Johnson Drive Right Bank	910.59	0.35 ft above Johnson Drive gage reading
3	Johnson Drive Left Bank	910.6	0.36 ft above Johnson Drive gage reading
4	Merriam Marketplace Right Bank	907.4	Water reached corner fence line on property immediately north of pavilion
5	Merriam Marketplace Left Bank	907.36	Groundhogs angry about their homes being flooded
6	Turkey Creek Trail Tree Line	904.97	Short section of trail was underwater just north of marketplace ped bridge.
7	Waterfall Park	891.22	Pretty significant flooding of industrial area next to park due to being a low spot
8	Lamar Avenue Offramp (NB I-35)	846.42	I-35 near Lamar Avenue was between 2-4 feet underwater

E.1.3. Hydrological Development from Feasibility Study

The hydrology of Turkey Creek upstream of the Johnson and Wyandotte County line is dominated by groundwater sources during baseflow conditions and surface water runoff during precipitation events. The amount of impervious cover associated with urban development (approximately 30 percent) had increased the rate of stormwater runoff reaching the creek, thereby causing an increase in the peak discharge volumes of Turkey Creek following storm events. The amount of impervious cover within the Turkey Creek watershed has likely reduced groundwater recharge, thus reducing the baseflow in portions of Turkey Creek. Baseflow conditions of Turkey Creek at 67th Street, just upstream of the study area, were recorded at approximately 1 cubic foot per second (cfs) as part of a field study conducted by the U.S. Geological Survey (USGS) in November 2000, and July 2003 (Lee, et al. 2005). Baseflow conditions downstream of the Johnson and Wyandotte County line are dominated by discharges from the Myron Nelson Wastewater Treatment Plant Complex and typically average around 25 cfs. No active USGS gage stations exist on Turkey Creek. Stormwatch gages record stages only.

This study's existing conditions associated with land use, imperviousness, rainfall runoff, and storm drainage systems are captured in a HEC-1 model and a HEC-RAS model. Hydrologic modeling of existing conditions began on 31 May 2005, when the Larkin Group Inc. began a study titled, The Northeast Johnson County Watershed Study for Johnson County, Kansas to assist the county in FEMA Flood Insurance Rate Map (FIRM) revisions for three or four of the smaller and well-developed watersheds of the county (Larkin Group Inc. 2005). Larkin Group Inc. produced the study for the Storm Management Program of Johnson County, Kansas, Public Works. As part of the study, Larkin Group Inc. developed a hydrologic model using the HEC-1 software. Many of the existing enclosed storm drainage systems needed specific assumptions and analytical processes, specifically for setting up an open channel flow tool, to best characterize the watersheds in northeastern Johnson County, which is the portion closest to the center of the Kansas City metropolitan area.

The HEC-1 model produced by Larkin Group Inc. included the complete watershed contributing to Upper Turkey Creek. During the early stage of the Feasibility Study (FS), planners and hydraulic engineers in the Kansas City District decided to use Larkin Group Inc.'s HEC-1 model as the official existing conditions hydrologic model for the Johnson County, Kansas, study.

Gages help to establish existing conditions by tying possible flows to statistical records. One USGS stream gage lies within the northeastern watershed. However, this gage, identified as Gage 06893557, is on Brush Creek located near Ward Parkway in Kansas City, Missouri. The gage monitors Brush Creek downstream of the northeastern watershed study area. USGS has reported data for this gage since 1999, and the average annual mean stream flow for this gage is 10.31 cfs. Based on conversations with Don Wilkinson of USGS in 2002, the 100-year flow at this location has been estimated at approximately 16,000 cfs based on variety of source data, but not enough data has been collected from the gage to verify this estimate. Although this gage is not directly related to Turkey Creek, it was an important calibration tool for Larkin Group Inc. during the preparation of the Johnson County, Kansas, HEC-1 model. Johnson County Public Works maintains a stream gage network, which is part of the Stormwatch system (City of Overland Park, 2012) and available on the internet, consisting of five gage stations within the area included in the northeast Johnson County, Kansas, watershed study area. Two of these stream gage stations are within the Turkey Creek watershed (Table E.5). These gage stations are not set up for streamflow measurement; they collect precipitation and water level data.

Table E.5. Turkey Creek Watershed Gages in the Stormwatch Gage Network

Gage	Location	Oldest Available Record
3010	Johnson Drive	14 September 1999
3020	65th Street	23 March 2000

The large majority of the northeast Johnson County watershed study area is fully developed and urbanized, including the Turkey Creek watershed. A quantitative analysis of existing land use was not required for the study because the required hydrologic data was acquired from a detailed study of impervious surfaces. However, the study area can be roughly characterized as follows:

- About 36 square miles of the northeast portion of the Johnson County study area are urbanized and fully developed. About 0.5 square miles of undeveloped land planned for future development are present in the Lake Quivira watershed in western Shawnee, Kansas. This undeveloped land is either pasture or woodlands. Open areas are also present in the community of Lake Quivira, but the planned use for those areas is to remain wooded open space.
- About 60 to 70 percent of the urban area is residential usage (subdivisions of single-family homes, multi-family dwellings, and apartment complexes).
- About 20 to 25 percent of the land is used for commercial, business, or institutional uses, including retail shopping, restaurants, entertainment, offices, hospitals, schools, churches, and synagogues.
- Less than 5 percent of the urban land is used for light industries.
- The remainder of the urban land is open space (such as floodplain areas), parks, golf courses, or transportation corridors.

- The average percent imperviousness for the Feasibility Study area was approximately 38 percent.
- According to the 2021 National Land Cover Database (NLCD) impervious layer dataset, Turkey Creek watershed is approximately 42.2% impervious surface.

The basin experienced significant development in the 1980s and 1990s and used up most remaining developable land. This contributed to increased Turkey Creek stormwater flows; however, no flows are expected to increase in the future due to additional impermeable surfaces.

E.1.4. Hydraulic Model Development

The Stantec 2D model was adopted for use in the Upper Turkey Creek design project. The hydraulic model was adopted because it had undergone some level of calibration and validation with historic rainfall events. This 2D model was developed on behalf of FEMA and Johnson County, Kansas, with expectations to become the new effective FEMA model for the Turkey Creek watershed. Using the same base model would be ideal to maintain consistency with FEMA for possible future levee accreditation. The Stantec model was developed to perform both hydrologic and hydraulic computations, providing rainfall runoff flood mapping for interior drainage analysis as well as the hydraulic analysis of the Turkey Creek channel from local inflows.

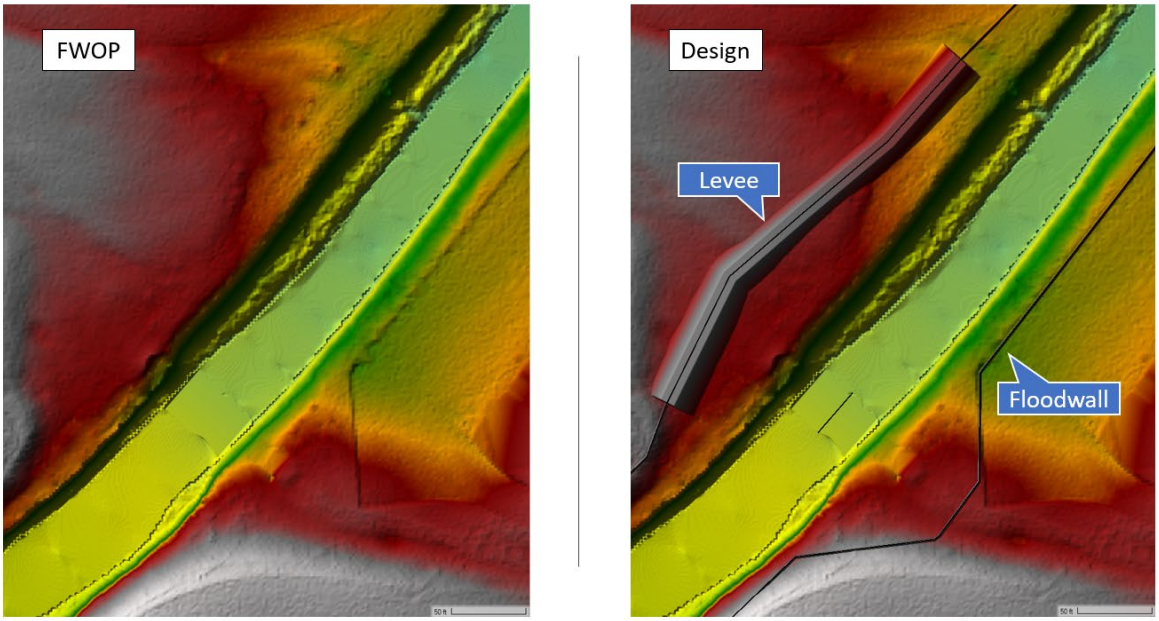
E.1.4.1. Terrain Modifications

Terrain modifications were used to represent proposed levees and floodwalls within the project area as well as modifications to the channel to account for bridge widening. With these modifications, two copies of the terrain were utilized. One copy represented the future without project conditions (FWOP), and one represented the 50% design. Table E.6 provides names and descriptions of the terrains used in the hydraulic model. An example of the FWOP vs. 50% design conditions is shown in Figure E.10.

Table E.6. Stantec 2D Model Terrain Descriptions.

Terrain Name	Description
Turkey	Stantec model existing conditions watershed terrain
Turkey_50%_Design	Stantec model watershed terrain with proposed levee/floodwall

Figure E.10. Terrain Modifications – FWOP vs. Design.



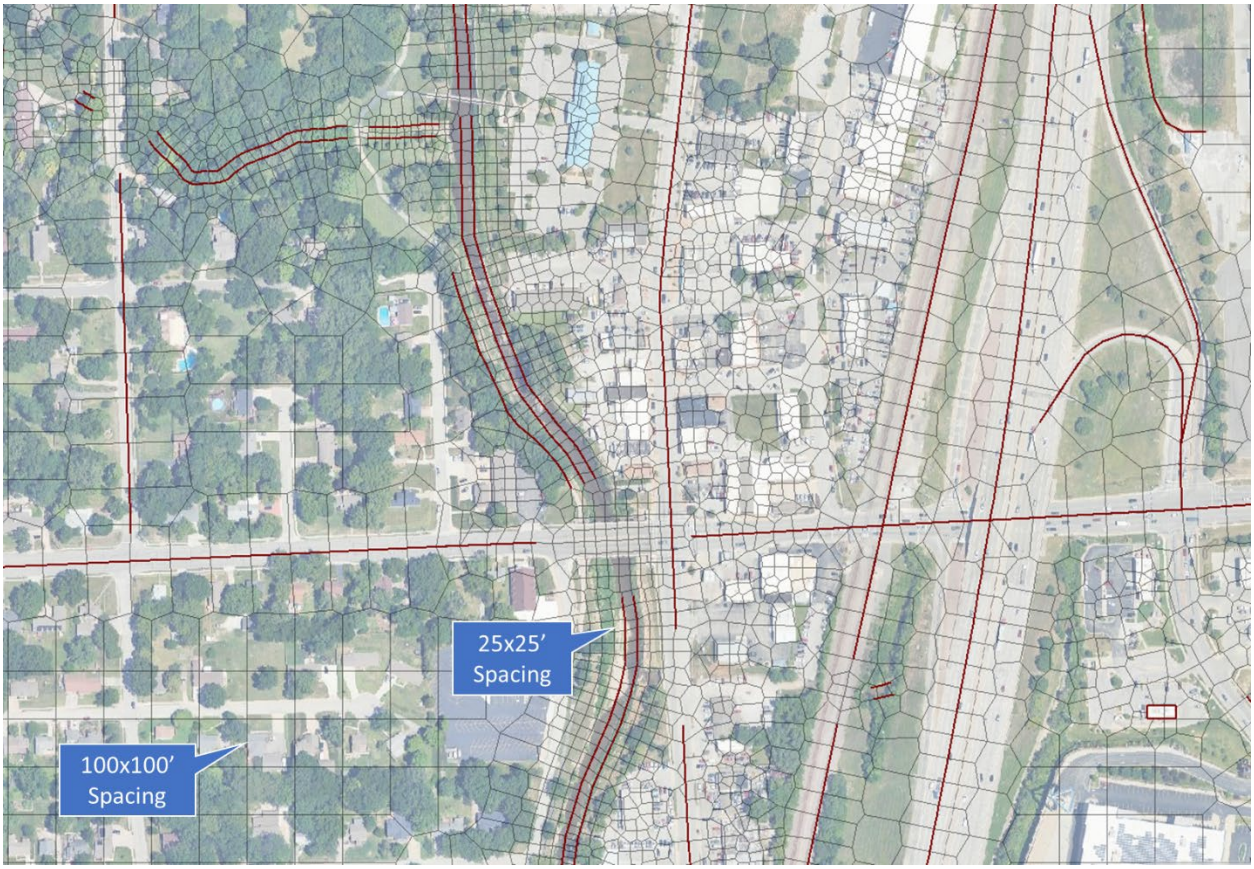
E.1.4.2. 2D Mesh

As mentioned previously, the hydraulic model is configured as fully 2D. The project area is represented by 2D cells of varying sizes along with refinement areas and breaklines to enforce instances of high ground (levees, floodwalls, roadways, etc.) and flow direction. Cell sizes outside of the channel and floodplain area generally used a 100x100 foot spacing. Cell sizes in the channel generally targeted a 25x25 foot spacing so the velocity variance, superelevation, and flow direction could be better represented. Cell spacing in the floodplain varied between 25 feet to 100 feet to represent roadways, buildings, and other features of the interior area. Figure E.11 provides a sample of the 2D mesh within the project area.

Breaklines were utilized in the Turkey Creek channel and other minor tributaries to better align cell faces perpendicular to flow direction. Breaklines were placed along major roadways which typically act as minor high ground. While not shown in the figure, breaklines were also placed on top of the floodwall and levee crest alignments to enforce the proposed levee heights.

Cells were generally adjusted to encompass building or structure footprints so that representative roughness values could be assigned to these locations. This is discussed in further detail in Section E.1.4.3.

Figure E.11. Example of 2D Mesh in Project Area.

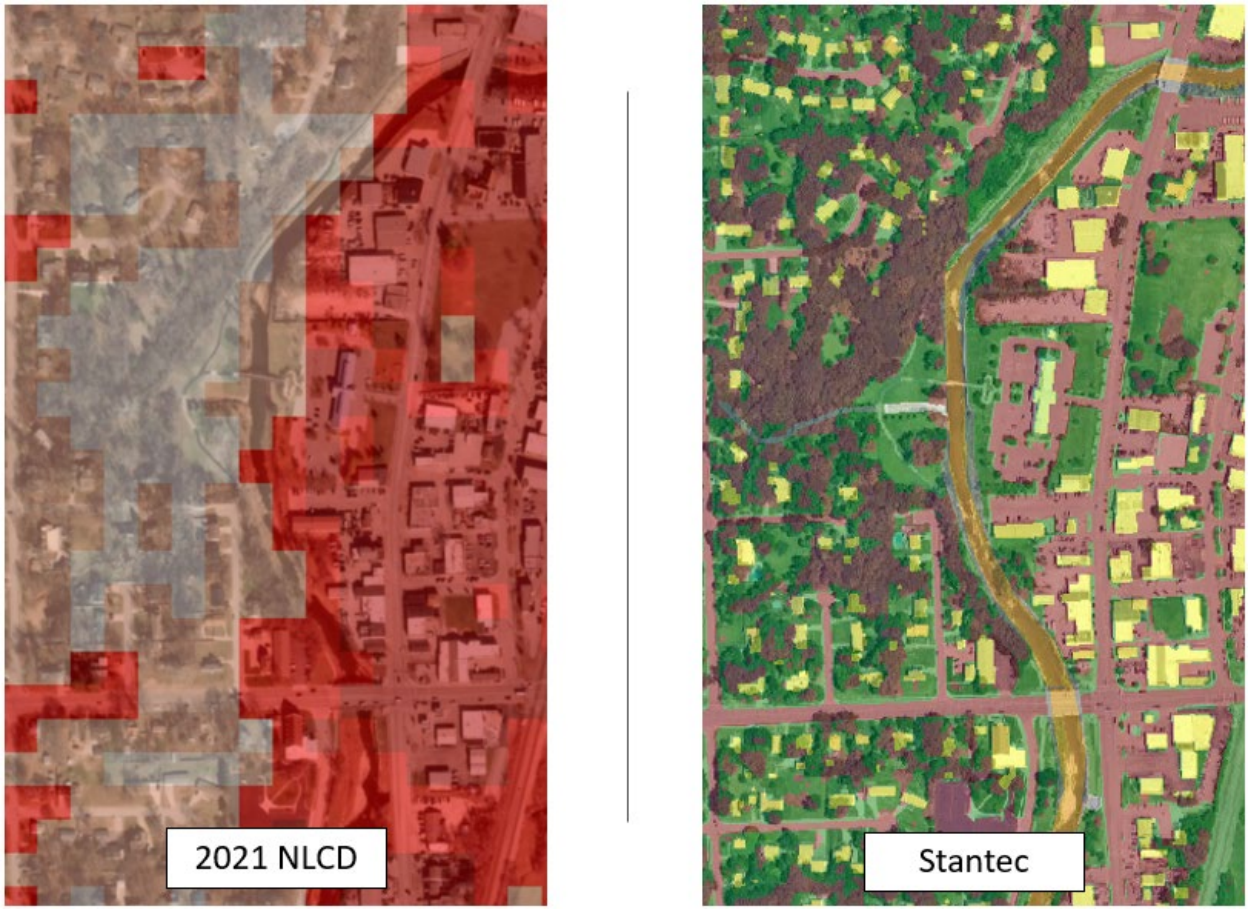


E.1.4.3. Land Cover Data

Land cover data was developed by Stantec as part of the 2D hydraulic model using recent aerial imagery provided by Johnson County's Automated Information Mapping System (AIMS) website. The NLCD land cover layer is typically used for 2D hydraulic modeling. The NLCD land cover layer uses a 30-meter resolution which is too coarse for the relatively smaller project area of Upper Turkey Creek and lacks the necessary detail required of an extensively urbanized watershed.

Figure E.12 below provides a side-by-side comparison of the Stantec developed layer and the NLCD layer. Stantec's land cover layer uses very detailed classification boundaries to acknowledge roadways/parking lots, buildings, channels, trees, and grass cover. The NLCD layer is too coarse to recognize Turkey Creek as open water and occasionally represents the channel as high intensity developed area. While edits could be made to the NLCD layer, the Stantec land cover layer was deemed more suitable for use. This is because of the greater detail in land cover type boundaries and usability improvements to make sweeping changes to roughness coefficients for any given land cover type.

Figure E.12. Land Cover Layer Comparison.



Land Cover types were broken up into the following categories to further discretize from the typical NLCD land cover types and assigned Manning's n values as shown in Table E.7.

Table E.7. Manning's N Values.

Land Cover Type	Manning's N Value
Barren Land	0.025
Buildings	0.5
Grass	0.03
Open Water	0.035
Pavement	0.015
Trees	0.06
Natural Channel	0.035
Concrete Channel	0.015
Riprap	0.045
Turkey Creel Channel1	0.032-0.035

1Calibration region to capture full channel widths of creek. Uses same value as Natural Channel

E.1.4.4. Infiltration Layer

An infiltration layer was also developed by Stantec in their initial modeling development. The Soil Conservation Service (SCS) Curve Number (CN) method was utilized. Development of the infiltration layer used aerial imagery and the Soil Survey Geographic Database (SSURGO) Soil Data layer. For more information, the Stantec modeling report can be viewed in Appendix E.7. It should be noted that infiltration layer is only used when running 2D rain-on-grid simulations. Given that the levee design hydraulic analysis did not use 2D rain-on-grid, the associated infiltration layer had no impact on the hydraulic results.

E.1.4.5. Boundary Conditions

The most notable modification to the Stantec 2D model was switching from the rain-on-grid boundary condition and importing the channel inflow boundary conditions used in the USACE 2D RAS model. This was necessary to maintain consistency with previous methodology of hydraulically routing the frequency flows and ensure flow volume remained the same as before. Using 2D rain-on-grid has notable limitations for purpose of developing channel water surface profiles for flood protection designs, especially in such urbanized areas with expansive stormwater networks. Stormwater pipes can significantly reduce time of concentration compared to overland flow which the 2D RAS model is limited to. Additionally, storm networks can route flow to different channel inflows points than what would occur naturally.

Boundary conditions include the upstream inflow location for the Turkey Creek channel on the upstream side of 67th Street bridge, a downstream boundary located just east of Roe Lane, and lateral inflow locations as dictated by the HEC-1 output locations. The downstream boundary used the normal depth condition with a friction slope of 0.00561 based on the channel bed slope in this location.

Boundary conditions were added within the 2D mesh to represent local inflows from tributaries and notable stormwater outlets into Turkey Creek according to output locations set in the HEC-1 model. Boundary condition names correspond to HEC-1 output hydrograph names for consistency. Table E.8 summarizes the boundary conditions ordered from upstream to downstream by river mile as well as general location.

Table E.8. Inflow Boundary Conditions for USACE 2D Model.

Boundary Condition	River Mile	Location
*TC-M80 XS 4.234 TCC23	4.234	67th Street bridge
TC94	3.990	1350ft downstream of 67th Street
TCT71	3.726	Tributary on upstream side of SMP bridge
TC-T59	3.670	Tributary on downstream side of SMP bridge
TC66	3.670	Tributary on downstream side of SMP bridge
TC79	3.153	400ft upstream of Johnson Drive
TCT50-TC64	3.112	220ft upstream of Johnson Drive
TC-T40	2.883	Upstream side of Merriam Marketplace bridge
TC57	2.836	160ft downstream of Merriam Marketplace bridge

Boundary Condition	River Mile	Location

TC48	2.336	1500ft downstream of Merriam bridge
TC38	2.185	600ft upstream of Hwy I-35 bridge
TC19	2.090	Tributary on upstream side of Hwy I-35 bridge
TC-T30	2.090	Tributary on upstream side of Hwy I-35 bridge

*Note: Upstream boundary condition

E.1.4.6. Bridges

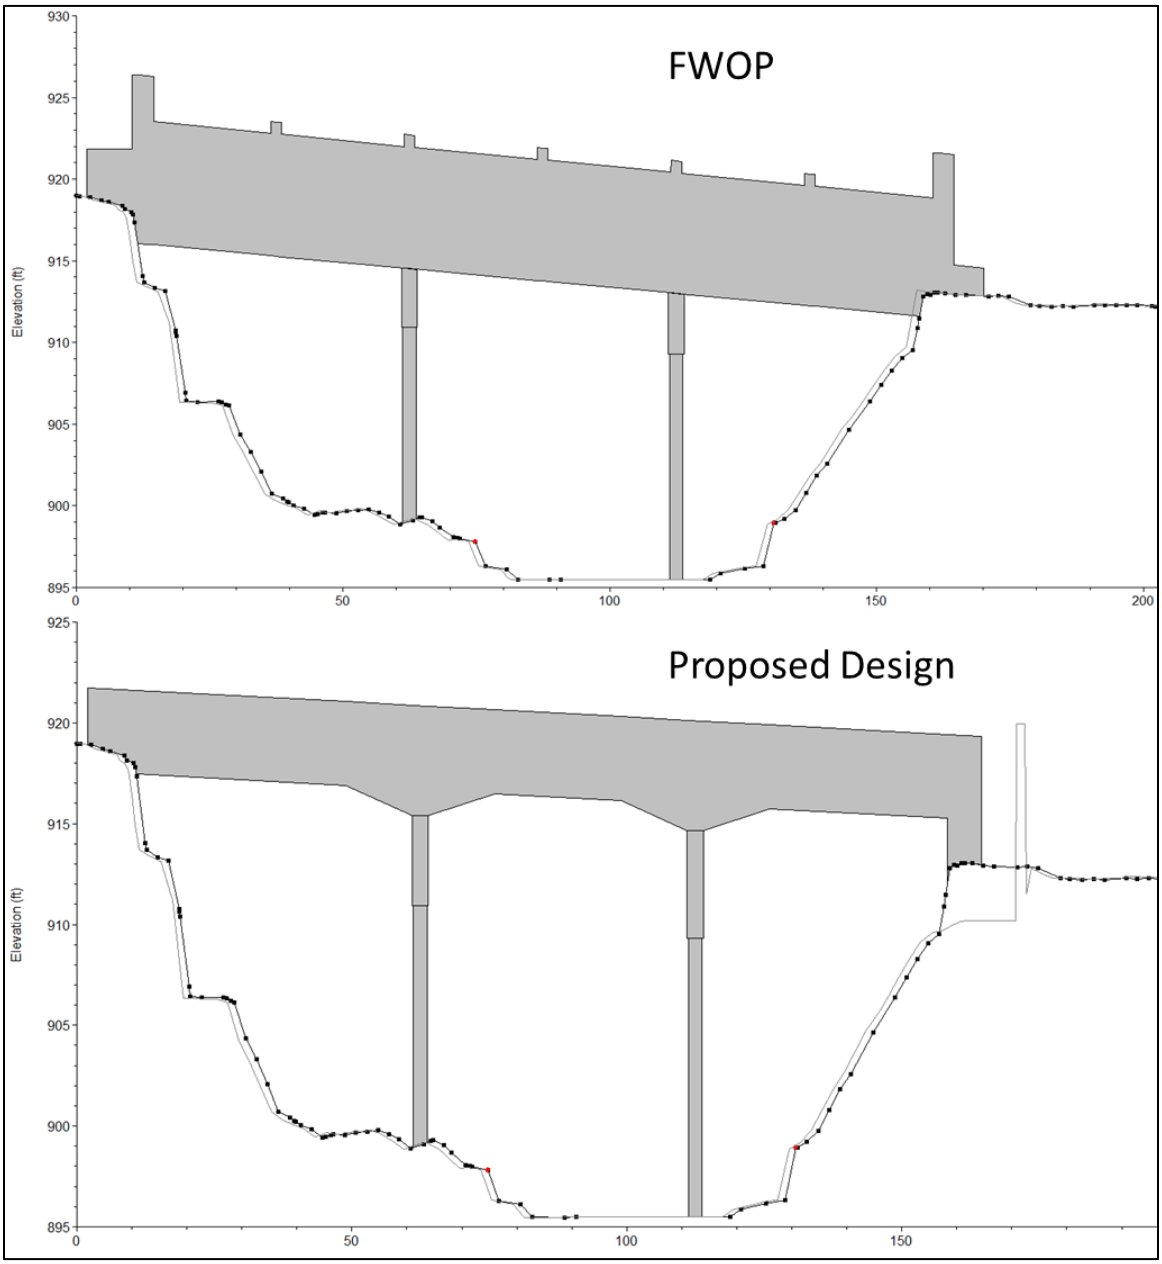
Bridges were added into the 2D model as 2D connections. Within the modeling extents, ten bridges spanning the Turkey Creek channel were identified. Bridges consist of vehicular, pedestrian, and railroad bridges. The location and description of bridges are summarized in Table E.9. Dimensions and heights for most bridges were based on drawings provided from Johnson County. The Merriam Marketplace bridge and DS Bus Line bridge geometries were based on USACE surveys. The 2D Equation Domain was selected for the overflow computation method for all bridges. Additionally, all bridges used a weir coefficient value of 2.

Table E.9. Bridges within Stantec FEMA 2D Model Extents.

Bridge (Model Ref)	Description	Approx. River Mile
67th Street Bridge (TUR_2600)	Vehicular bridge along 67th Street in Merriam, KS	4.25
Shawnee Mission Parkway Bridge (TUR_2300)	Vehicular bridge along SMP/63rd Street	3.73
Shawnee Mission Parkway Pedestrian Bridge (TUR_2200)	Pedestrian Bridge approx. 600ft downstream of SMP	3.57
Johnson Drive Bridge (TUR_1900)	Vehicular bridge along Johnson Drive	3.07
Merriam Marketplace Pedestrian Bridge (TUR_1700)	Pedestrian bridge connects TurkeyCr Streamway Trail (left bank) to Merriam Mrkt/Commercial area (right bank)	2.87
Merriam Drive Bridge (TUR_1500)	Vehicular Bridge along Merriam Drive	2.66
DS Bus Line Bridge (TUR_1400)	Small vehicular bridge connecting school bus parking area to alternate access to Merriam Drive	2.49
BNSF Trestle Bridge (TUR_1100)	Railroad bridge for BNSF adjacent to I-35	2.07
Highway I-35 southbound on-ramp (TUR_1000)	Vehicular bridge serving as onramp to SB I-35 from Antioch Road	2.02
Highway I-35 (TUR_900)	Vehicular bridge for Hwy I-35	2.00

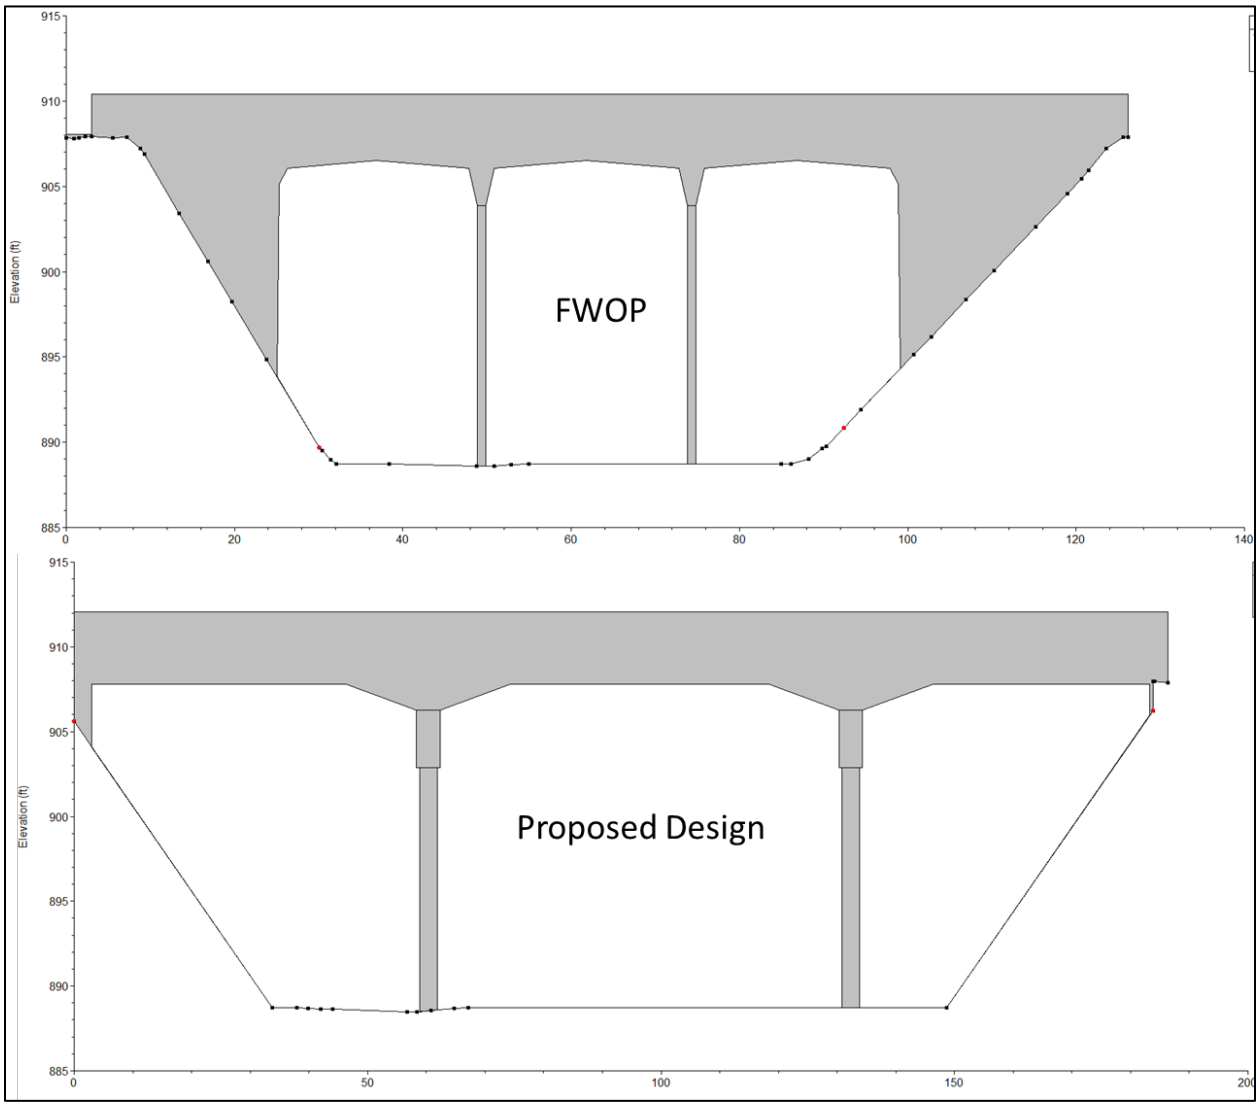
Part of the 50% design includes replacement of both the Johnson Drive bridge and Merriam Drive bridge. These two bridges were updated in the hydraulic model for the 50% design geometry. Structural calculations showed that the existing Johnson Drive bridge would experience flotation during the 1% AEP design event. The proposed replacement is a Kansas Department of Transportation (KDOT) standard slab bridge. Additionally, the bridge is being raised so that it acts as part of the flood protection system and eliminates the need for closure structures on the left and right sides of the bridge deck. The proposed Johnson Drive bridge replacement geometry is shown in Figure E.13.

Figure E.13. Johnson Drive Bridge Replacement.



The Merriam Bridge will be replaced due to the low conveyance capacity of the current bridge. The openings are not aligned with flow direction, and the bridge overtops during the 1% AEP event. Like Johnson Drive, a standard KDOT slab bridge is proposed to replace the existing bridge at Merriam Drive. It should be noted that the channel will be widened to accommodate a longer bridge span which helps further increase flow conveyance. Figure E.14 provides a comparison between FWOP and the 50% design.

Figure E.14. Merriam Drive bridge replacement.



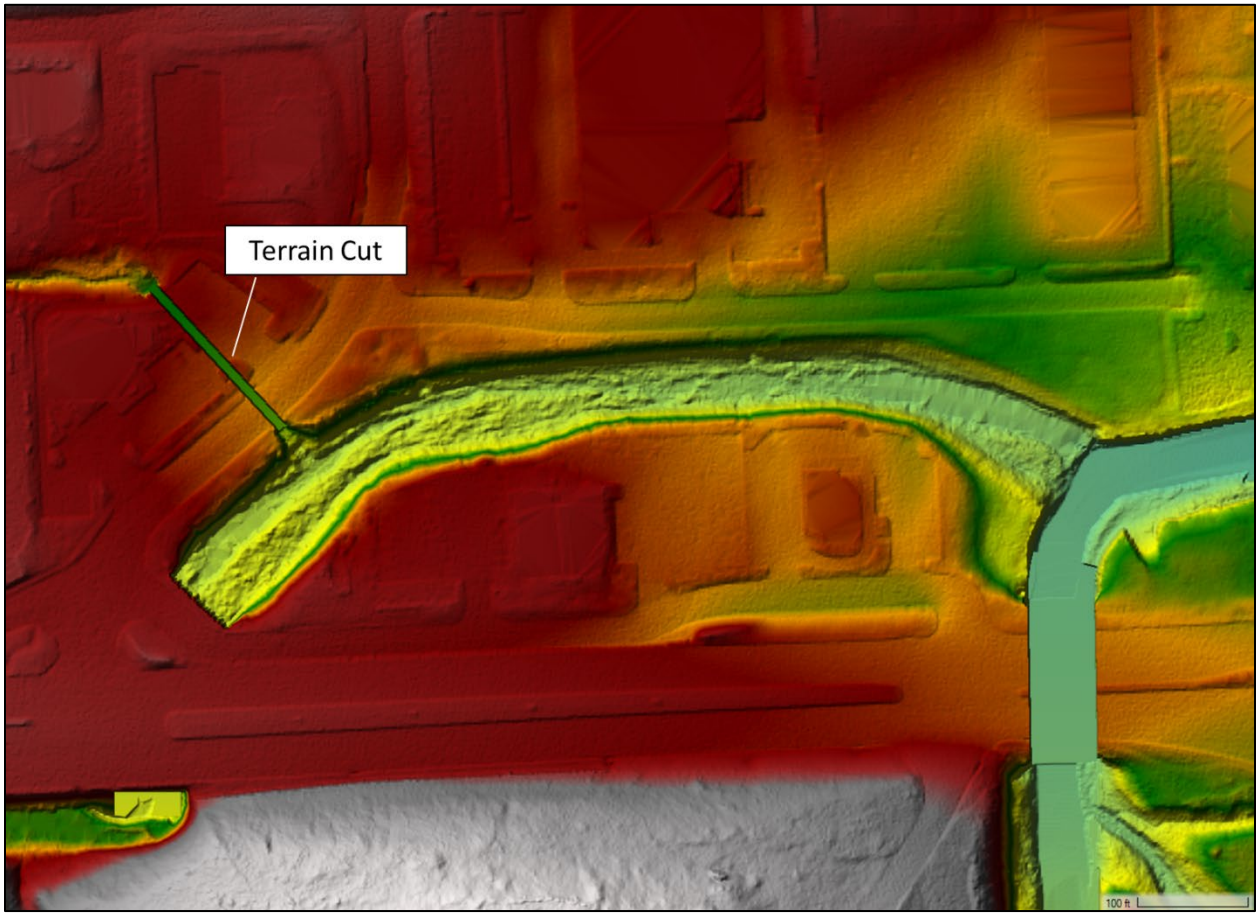
E.1.4.7. Miscellaneous Refinements

Other refinements to the Stantec 2D model include refinements to cell alignments both in the channel and floodplains. Cell alignment was adjusted to better represent flow direction in the channel. This improved model stability and runtime while providing more representative results.

Any terrain modifications used to assist with rain-on-grid modeling were removed. These included cuts into the terrain to allow rainfall runoff to route towards Turkey Creek in place of

modeling storm water networks. An example of this is shown below at the tributary just north of Shawnee Mission Parkway.

Figure E.15. Example of Removed Terrain Modification.



E.1.5. Levee Profile Development

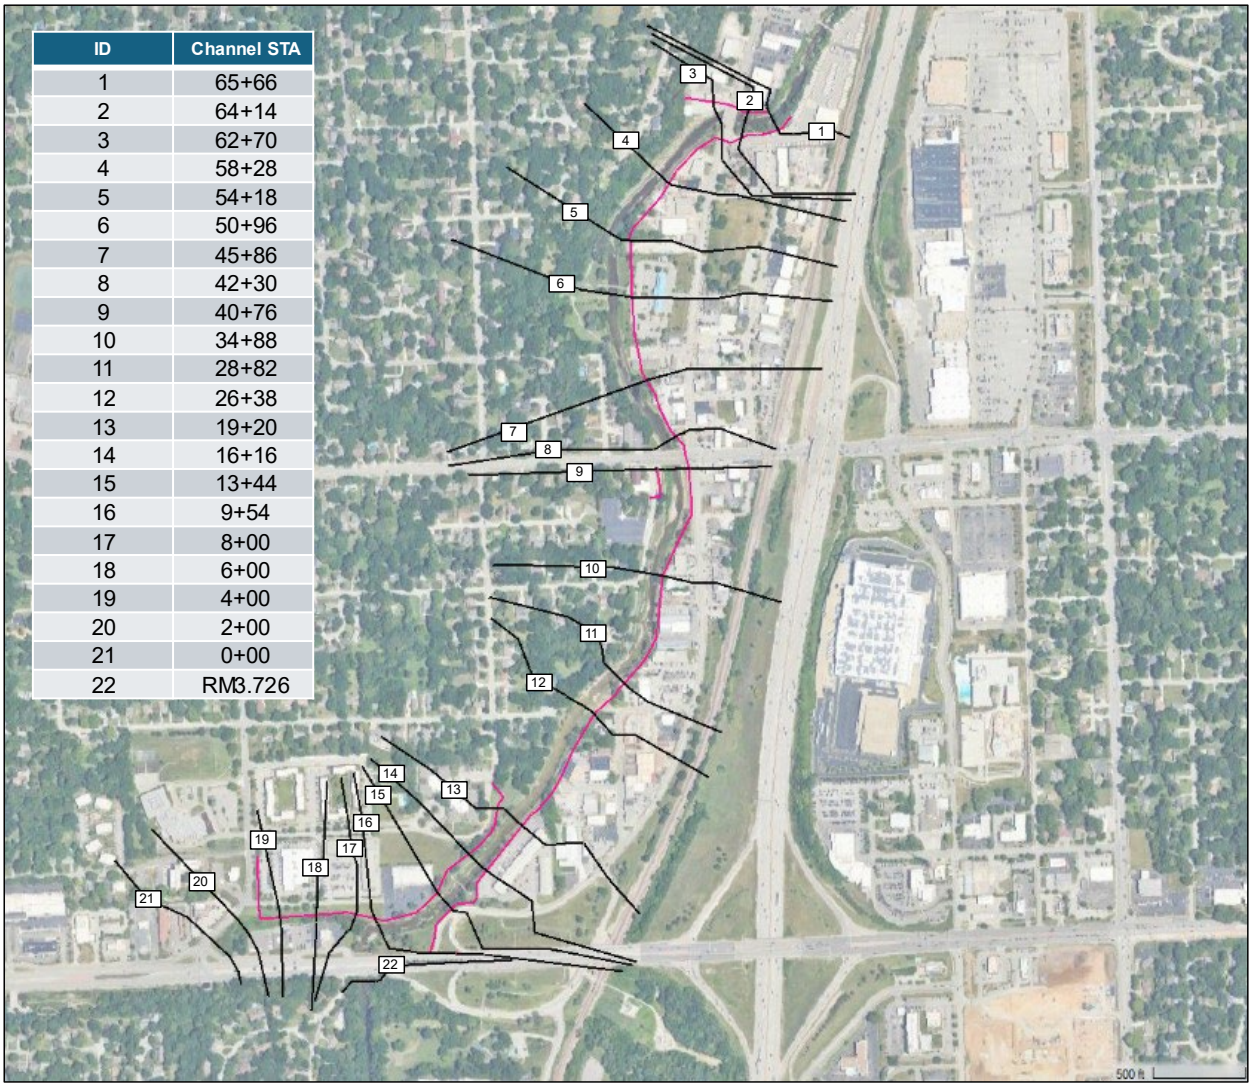
Development of the levee profile was a multi-stage effort. Levee height was determined through risk-based analysis outlined in EM 1110-2-1619. Hydrologic Engineering Center Flood Damage Reduction Analysis (HEC-FDA) software was used to determine levee height with a required assurance level based on HEC-RAS model outputs. This included the following data for both the FWOP and with project conditions at each index location.

- Unsteady HDF plan files
- Frequency Functions (Flow Frequency Curve)
- Stage Transform Functions (Rating Curve)
- Lateral Structures (Levee Alignment Shapefile)

E.1.5.1. Index Locations

Before outputting hydraulic data from HEC-RAS, index locations were identified. More index locations are typically needed for purposes of levee design, especially in highly dynamic systems such as Turkey Creek. More index locations allow the levee profile to capture inflection points in the channel water surface profile, particularly upstream and downstream of bridges, and at notable changes to the bed slope. The initial set of index locations used the cross-sections from the previously developed 1D hydraulic model. This allowed for easy points of comparison when looking at changes to levee height from previous iterations. Additional index locations were added along the tributary at the upstream portion of the project. Figure E.16 below provides a visual of the index locations used for HEC-FDA. Additionally, the levee alignment shapefile for both the left and right banks was provided.

Figure E.16. Index Locations.



E.1.5.2. Unsteady Plan Sets

HEC-FDA requires a set of frequency plans to develop stage-transform function (rating curves) and associated uncertainty bounds at each index location. This consists of the 50%, 20%, 10%, 5%, 2%, 1% 0.5%, and 0.2% AEP flows. The set of 8 flow frequency plans was needed for the FWOP and with design conditions. Additionally, 4 additional sets of plans were run to develop stage uncertainty associated with each frequency flow in FWOP and with design conditions. Generally, the Manning's n value for the FWOP and with design conditions was modified +/- 30% to represent uncertainty in the stages. These plans are discussed in detail in Section E.1.5.4**.** In total, 48 plans were necessary to perform the HEC-FDA analysis to develop the levee profile. Despite a stage uncertainty being developed for each frequency for both the FWOP and with design conditions, the maximum computed value was used for all frequencies when input into HEC-FDA to reduce the risk of underestimating stage variability. Especially for the 1% AEP design event. This was 0.460-feet and 0.468-feet for the FWOP and with design conditions, respectively.

E.1.5.3. HEC-RAS Model Outputs

Flows and water surface elevations were pulled to develop flow frequency curves and rating curves at each index location. It should be noted that flow was measured using the index cross-sections across the entire floodplain to properly capture all conveying flow. Conversely, the water surface elevation was only measured within the extent of the channel, even for floodplain wide flows. This was necessary to ensure that the computed levee height would have the proper level of assurance compared to the design water surface profile in the channel. To take superelevation into account, water surface elevations were manually pulled from the model outputs on the left and right banks. Figure E.17 provides an example at channel STA 64+14 which is immediately downstream of the Merriam bridge. At this location, the right bank (outside channel bend) experienced a superelevation of approximately 0.8-feet relative to the left bank and 0.4-feet relative to the center of channel. An example of the flow and stage data is provided in Table E.10 at the same location which illustrates the difference in water surface elevation between left and right bank due to superelevation.

Figure E.17. Example of Water Surface Superelevation in Channel.

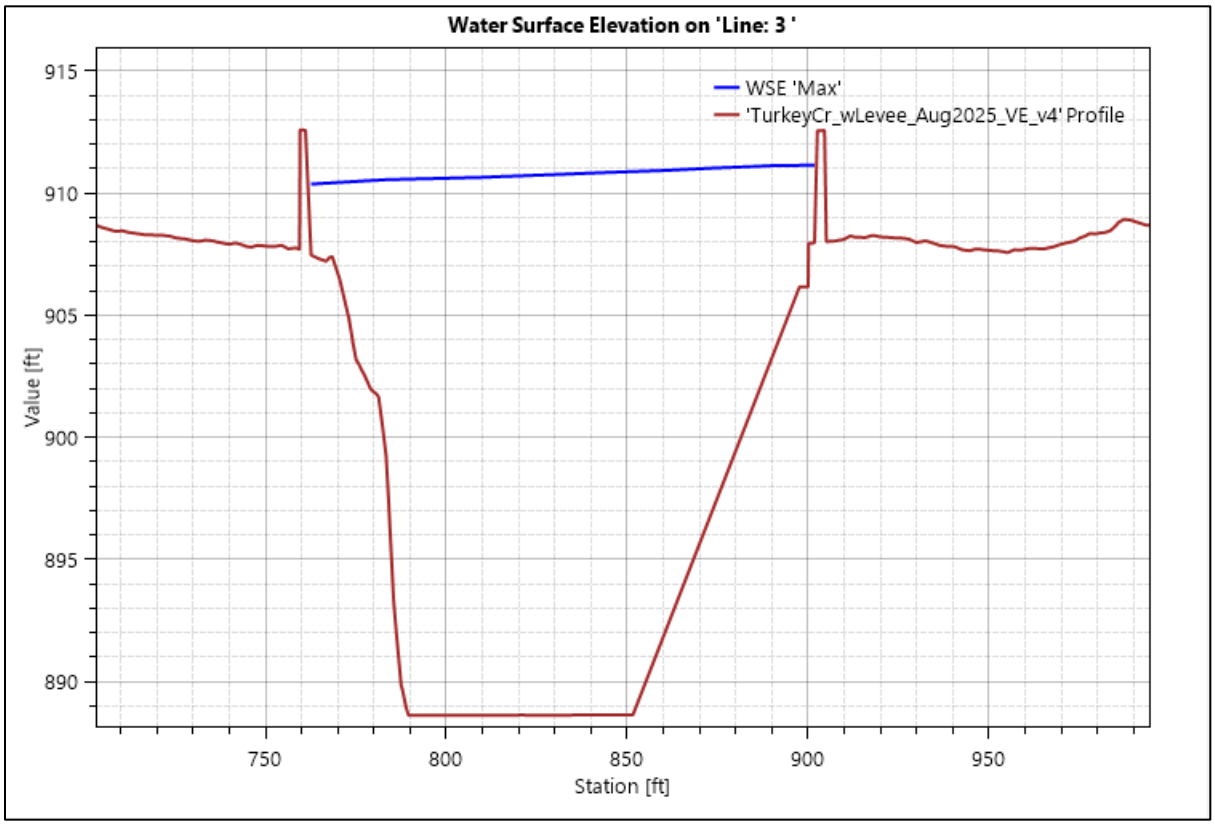


Table E.10. Example H&H Flow and WSE Input Data for HEC-FDA.

AEP	Flow	Water Surface Elevation (feet)		Δ WSE (ft)
		Left Bank	Right Bank	
50%	6823	901.94	902.42	0.48
20%	9185	904.12	904.76	0.64
10%	10930	905.57	906.35	0.78
5%	14268	907.88	908.37	0.49
2%	16502	909.20	909.71	0.51
1%	18674	910.38	911.15	0.77
0.5%	20405	911.09	912.29	1.20
0.2%	21879	911.48	912.60	1.12

The unsteady plan HDFs were needed to develop stage-damage functions for impacted structures in the FWOP and with design conditions. Stage-damage curves were not needed for computing levee height but were necessary for the economic analysis performed in HEC-FDA.

E.1.5.4. HEC-FDA Data Inputs

Stage Uncertainty

A sensitivity analysis was conducted during the levee profile design process to account for uncertainty in the hydraulic modeling. This process is outlined in EM 1110-2-1619, Section 5-7. In the absence of observed data, Manning's n values can be varied (typically +/- 30%) in the hydraulic model to develop and upper and lower confidence bound in frequency stages.

Manning's n values were varied +/- 30% for both the with and without project conditions. The difference in feet and standard deviation was computed to represent the stage uncertainty using methods outlined in EM 1110-2-1619. Table E.11 summarizes the average stage uncertainty across the project reach for each frequency. It should be noted that the results show stage uncertainty generally decreasing with smaller frequencies (larger events). This hydraulic behavior can be attributed to typical behavior of a stage-discharge rating curve where equal increases in flow result in smaller and smaller increases in stage as more of the floodplain is inundated. All HEC-FDA input data is available in Appendix E.3.

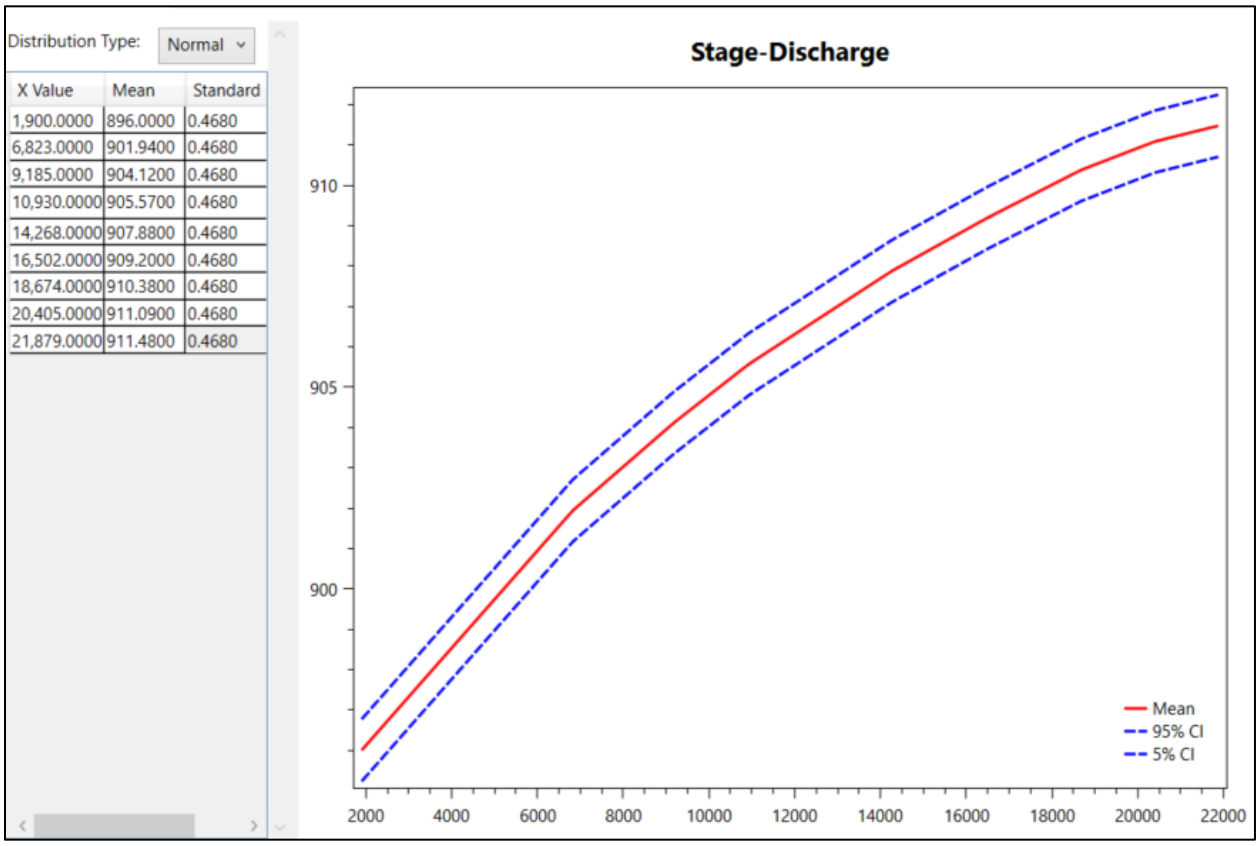
Table E.11. Manning's N Sensitivity Test for Stage Uncertainty.

AEP	FWOP		50% Design	
	Δ WSE (feet)	Standard Deviation (feet)	Δ WSE (feet)	Standard Deviation (feet)
50%	1.84	0.460	1.87	0.468
20%	1.46	0.364	1.67	0.417
10%	1.72	0.429	1.66	0.414
5%	1.19	0.298	1.59	0.397
2%	1.02	0.254	1.53	0.382
1%	0.85	0.213	1.32	0.329
0.5%	0.74	0.185	0.93	0.234
0.2%	0.62	0.154	0.54	0.136

Stage-Transform Relationship

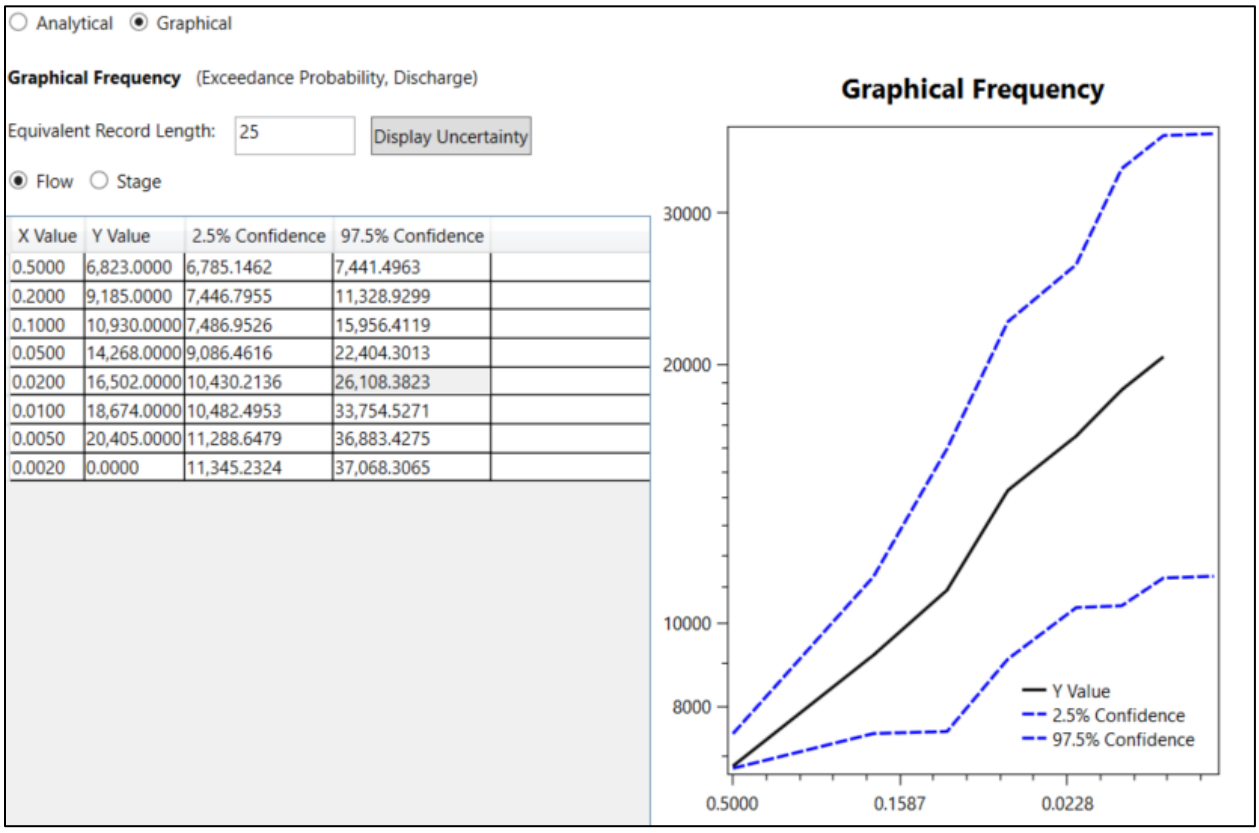
The stage-transform function (stage-discharge rating curve) uses a normal distribution type. This allows the user to input the stage-discharge for each frequency as well as the computed standard deviation. As mentioned previously, only the maximum respective value for the FWOP and with design conditions was used. The left bank index point at STA 64+14 is shown below as an example in Figure E.18. The data displayed is for the with design condition.

Figure E.18. STA 64+14 LB Stage-Discharge Curve.



The frequency function (flow-frequency curve) used the graphical method in the absence of observed data to develop a flow-frequency curve through HEC-SSP. The graphical method involves adding the peak flows measured at an index point for each corresponding frequency into a table. An equivalent record length must then be chosen for HEC-FDA to compute 2.5% and 97.5% confidence bounds. The equivalent record length was chosen to be 25 years to represent length of record of the Johnson Drive StormWatch stage gage. While this gage does not record flow, sub-daily observed stages at this location could be utilized to inform record length. Figure E.19 provides an example at index location STA 64+14.

Figure E.19. STA 64+14 Flow Frequency Curve.



E.1.6. Sensitivity Analysis

Sensitivity analyses were conducted to bracket uncertainty in the hydraulic modeling as well as understand the effect of parameter assumptions on the modeling results. In addition to the stage-uncertainty analysis discussed in Section E.1.5.4, a sensitivity analysis was also performed the downstream boundary condition of the hydraulic model.

E.1.6.1. Normal Depth Slope
