The normal depth friction slope at the downstream boundary of the model was varied to evaluate any effect on water surface in the project area upstream. It should be noted that the selected friction slope for the normal depth boundary condition was estimated using the bed slope at the downstream portion of the model. The friction slope was factored up and down by 2. Table E.12 provides a summary of water surface elevations at the downstream boundary and at Merriam Bridge for the selected friction slope and the slopes used for the sensitivity test. Factoring the base friction slope up or down by 2 has a negligible effect on the water surface at the project location. Changes to water surface elevation were less than a tenth of a foot.

Table E.12. Normal Depth Sensitivity Analysis

Scenario	Friction Slope (ft/ft)	WSE at Downstream Boundary	WSE at Merriam Bridge (ft)
Base	0.00561	811.8	910.9
2x Slope	0.01122	811.8	910.9
0.5x Slope	0.00231	811.8	910.9

E.1.6.2. Bridge Modeling Approach

The high flow methods available in the HEC-RAS bridge modeling approach are Energy method and the Pressure and/or Weir method. The HEC-RAS hydraulic reference manual generally recommends selecting the Pressure and/or Weir method if flow is being constrained down to only the bridge opening without flanking or overtopping. For instances where flow conveyance is not limited to pressurized flow through the opening, the Energy method is recommended. These high flow method selections were made for each individual bridge based on the if the 1% AEP design event would likely flank or overtop the bridge deck. Pressure and/or Weir method was selected for the Johnson Drive (TUR_1900), Merriam Drive (TUR_1500), BNSF Railroad (TUR_1100), I-35 On-Ramp (TUR_1000), I-35 (TUR_900).

A sensitivity test was conducted by switching the high flow method for all bridges within the study area to Energy Method only. Analysis of results showed that high flow methods impacted the 1% AEP water surface profile around Johnson Drive and Merriam Drive bridges as shown in Figure E.20. Using only Energy for the high flow method resulted in a decrease in water surface elevation upstream of Johnson Drive bridge (from STA 43+50 to 65+50) and an increase in water surface elevation upstream of Merriam Drive bridge (from STA 65+50 to 86+00). Table E.13 below provides the maximum and average change in water surface elevation over these two stretches. All other portions of the water surface profile changed by less than 0.1 feet.

Figure E.20. 1% AEP Profile Comparison – 50% Design vs Energy Method Only

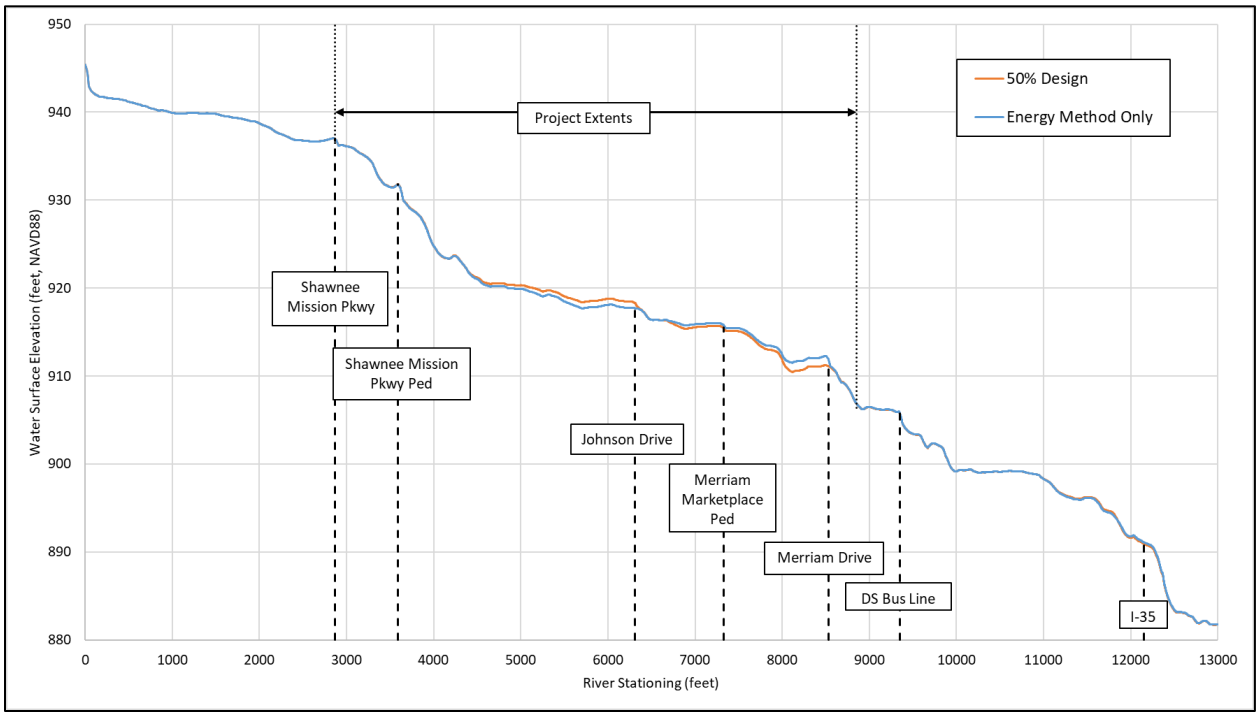

Table E.13. High Flow Bridge Modeling Approach Sensitivity Analysis

Location	Type	Change in WSE (ft)
Project Length	Max	1.07
	Average	0.00
Upstream Johnson Drive (STA 43+50-65+50)	Max	1.07
	Average	0.48
Upstream Merriam Drive (STA 65+50-86+00)	Max	-0.72
	Average	-0.44

Considerations should be given to variation in water surface profile with bridge modeling assumptions. But Pressure and/or Weir flow method is still deemed suitable for Johnson Drive and Merriam Drive bridges given that flow is fully constrained to flow through the bridge openings. Energy method is not applicable.

APPENDIX E.2 – FLOW INPUT DATA

HEC-1 Frequency Flow Hydrographs

E.2 FLOW INPUT DATA

Below are the flow frequency inflow hydrographs at each boundary location listed in the main report. These hydrographs were developed as part of the Upper Turkey Creek feasibility study using the HEC-1 hydrologic model. The boundary conditions are ordered from upstream to downstream.

APPENDIX E.3 – HEC-FDA H&H INPUT DATA

Introduction

50% Design Inputs

Post-35% Design Inputs

E.3 HEC-FDA H&H INPUT DATA

E.3.1 Introduction

The following tables include H&H data provided for the HEC-FDA levee profile update. This data includes standard deviation calculations, peak flows, and water surface elevations at each index location for the FWOP and with design conditions.

E.3.2 50% Design Inputs

E.3.2.1 Standard Deviation Calculations

Standard deviation was computed by taking the average water surface elevation difference along the entire project length between the +/-30% Manning's N value profiles for each frequency event. This is one of the methods to develop stage-uncertainty in the absence of observed data as stated in EM-1110-2-1619. The computed standard deviation serves as the uncertainty bounds for the stage-discharge rating curve as shown previously in Appendix E.1. This was done for the FWOP and with design conditions. Due to the very large amount of data, the water surface profiles were not included in the appendix. As shown below, the standard deviation for each frequency was computed, but only the max was used for HEC-FDA.

Table 1. Standard Deviations – FWOP Condition.

AEP	Average WSE Difference (feet)	Computed StDev	StDev for FDA (max)
50.0%	1.84	0.460	0.460
20.0%	1.46	0.364	0.460
10.0%	1.72	0.429	0.460
5.0%	1.19	0.298	0.460
2.0%	1.02	0.254	0.460
1.0%	0.85	0.213	0.460
0.5%	0.74	0.185	0.460
0.2%	0.62	0.154	0.460

Table 2. Standard Deviations – With Project Condition.

AEP	Average WSE Difference (feet)	Computed StDev	StDev for FDA (max)
50.0%	1.87	0.468	0.468
20.0%	1.67	0.417	0.468
10.0%	1.66	0.414	0.468
5.0%	1.59	0.397	0.468
2.0%	1.53	0.382	0.468
1.0%	1.32	0.329	0.468
0.5%	0.93	0.234	0.468
0.2%	0.54	0.136	0.468

E.3.3 Post-35% Design Inputs

E.3.3.1 Standard Deviation Calculations

Standard deviation was computed by taking the average water surface elevation difference along the entire project length between the +/-30% Manning's N value profiles for each frequency event. This is one of the methods to develop stage-uncertainty in the absence of observed data as stated in EM-1110-2-1619. The computed standard deviation serves as the uncertainty bounds for the stage-discharge rating curve as shown previously in Appendix E.1. This was done for the FWOP and with design conditions. Due to the very large amount of data, the water surface profiles were not included in the appendix. As shown below, the standard deviation for each frequency was computed, but only the max was used for HEC-FDA.

Table 3. Standard Deviations – FWOP Condition.

AEP	Average WSE Difference (feet)	Computed StDev	StDev for FDA (max)
50.0%	1.84	0.460	0.460
20.0%	1.46	0.364	0.460
10.0%	1.72	0.429	0.460
5.0%	1.19	0.298	0.460
2.0%	1.02	0.254	0.460
1.0%	0.85	0.213	0.460
0.5%	0.74	0.185	0.460
0.2%	0.62	0.154	0.460

Table 4. Standard Deviations – With Project Condition.

AEP	Average WSE Difference (feet)	Computed StDev	StDev for FDA (max)
50.0%	1.87	0.468	0.468
20.0%	1.67	0.417	0.468
10.0%	1.66	0.414	0.468
5.0%	1.59	0.397	0.468
2.0%	1.53	0.382	0.468
1.0%	1.32	0.329	0.468
0.5%	0.93	0.234	0.468
0.2%	0.54	0.136	0.468

APPENDIX E.4 – RIPRAP SIZING INPUT DATA

Design Criteria

Upstream Reference Cross-Section

Initial Computed Riprap Sizes

Cross Section Riprap Design

E.4 RIPRAP SIZING INPUT DATA

E.4.1 Design Criteria

Riprap sizing was computed in the HEC-RAS riprap sizing tool which uses design requirements outlined in EM 1110-2-1601. Riprap size is a function of channel/overbank geometry, stone unit weight, velocities, and safety factors.

E.4.2 Upstream Reference Cross-Section

Upstream reference cross-section data was pulled from the Turkey Creek channel upstream (south) of Shawnee Mission Parkway, outside of the project area.

Table E.1. Upstream Reference Cross Section Input Data

Parameter	Value
Average Channel Velocity	9.7 ft/s
Hydraulic Depth	10.3 ft
Channel Width	80 ft

E.4.3 Initial Computed Riprap Sizes

Initial riprap sizes were developed with the HEC-RAS tool for various sections along the left and right banks. Riprap sizes were consolidated to just three separate diameters to simplify the design as shown in Section 4.5.2 of the main report. Table E.2 and Table E.3 provide the initial computed riprap sizes for the left and right bank, respectively

Table E.2. Computed Left Bank Maximum Riprap Sizes

Channel STA	Velocity (ft/s)	D100 (in) (Gradation)
0+00-9+00 (Tribs LB & RB)	12	21 (EM 1601-5)
9+00-14+00	15	33 (EM 1601-9)
15+25-19+00	10	15 (EM 1601-3)
21+00-25+00	9	15 (EM 1601-3)
33+00-36+00	9	15 (EM 1601-3)
63+00-End	15	24 (EM 1601-6)

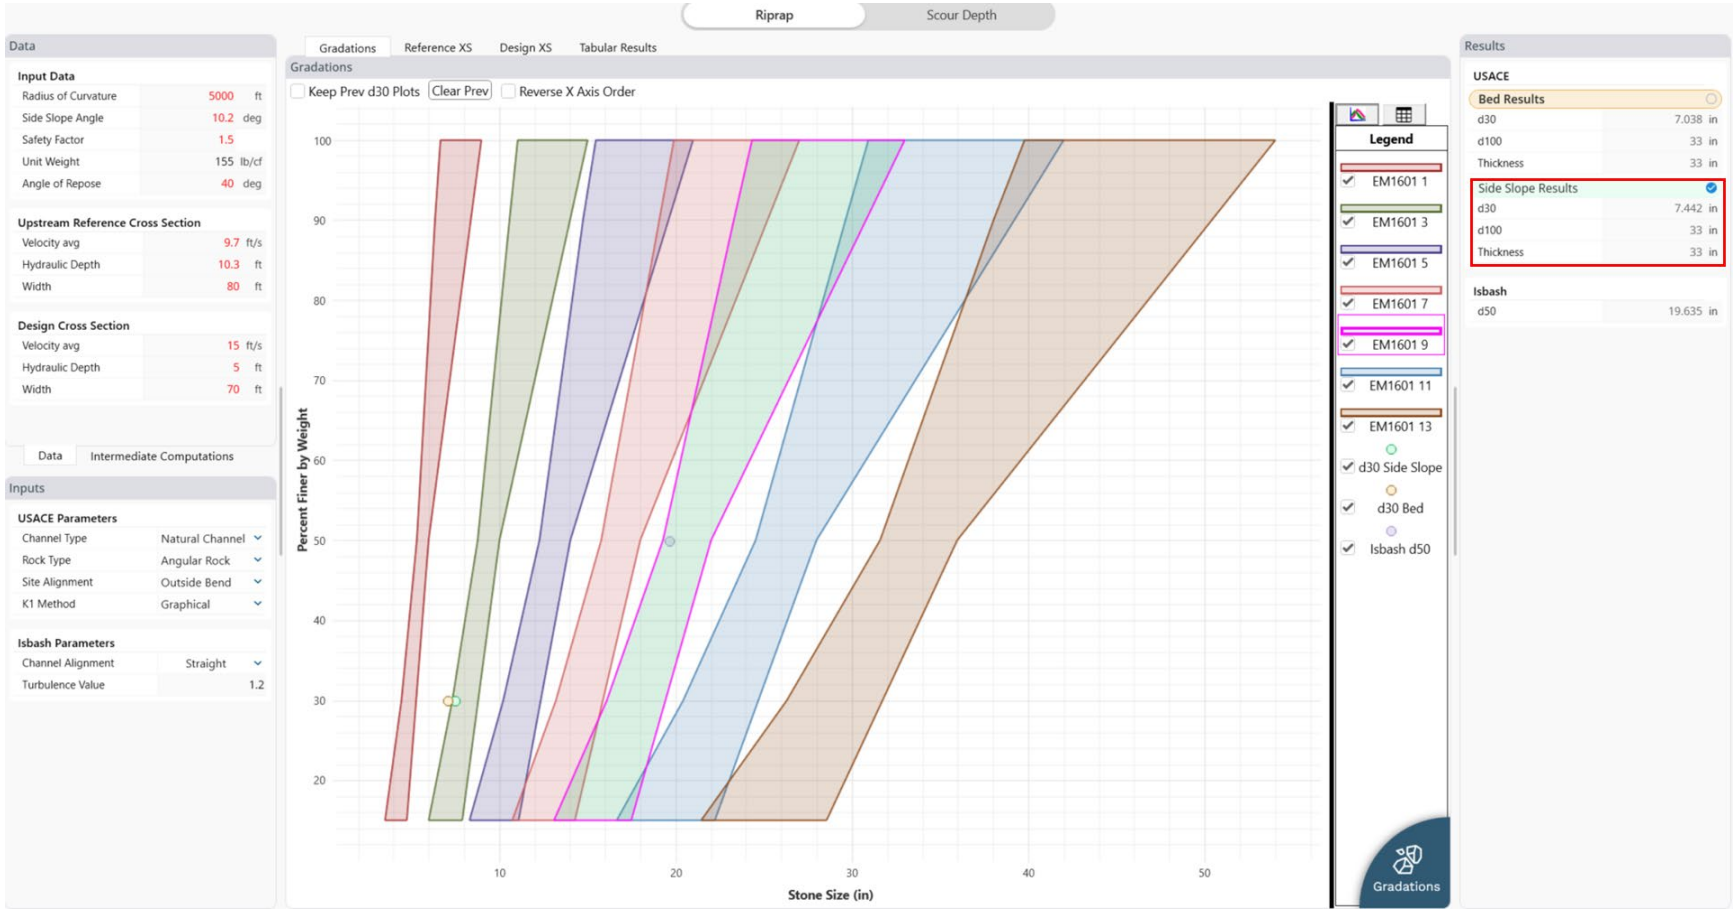
Table E.3. Computed Right Bank Maximum Riprap Sizes

Channel STA	Velocity (ft/s)	D100 (in) (Gradation)
15+25-19+00	10	15 (EM 1601-3)
19+00-26+00	9	15 (EM 1601-3)
30+00-33+00	9	30 (EM 1601-8)
33+00-36+00	12	21 (EM 1601-5)
36+00-42+00	9	21 (EM 1601-5)
42+00-48+00	12	21 (EM 1601-5)
53+00-57+00	12	21 (EM 1601-5)
57+00-60+00	15	33 EM (1601-9)
60+00-64+00	12	21 (EM 1601-5)
64+00-End	10	42 (EM 1601-11)

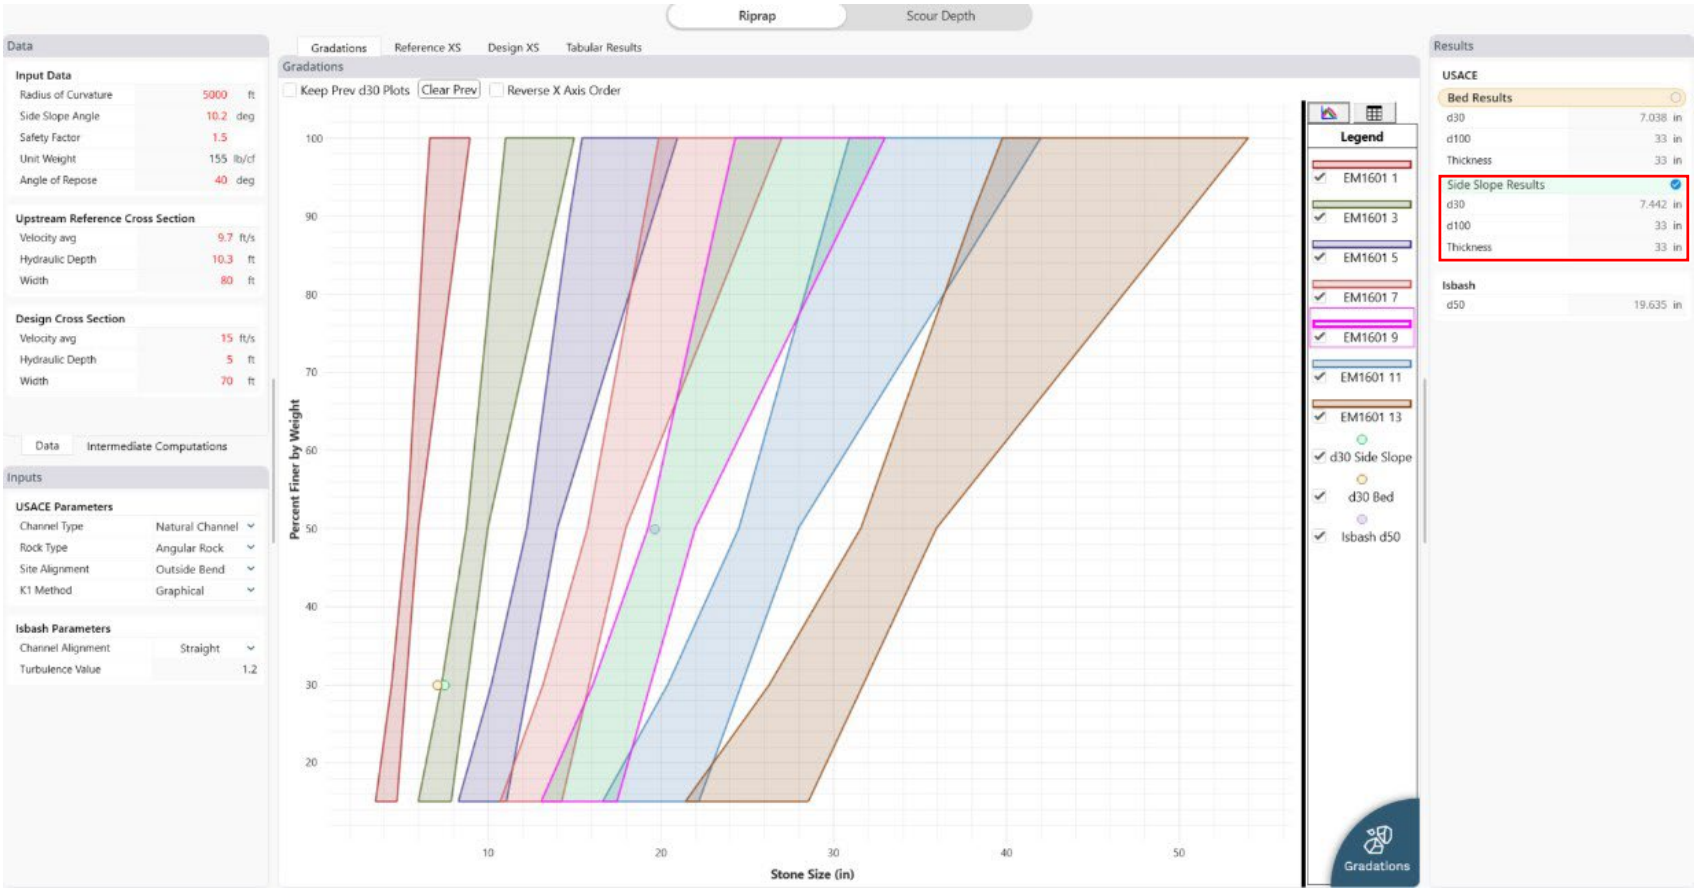
E.4.4 Cross Section Riprap Design

The following sections provide the riprap design information and calculations performed for each cross section. These figures detail the input parameters on the left side pane, and the selected gradation in the center that intersects with the plotted riprap sizing methods. On the right pane details that selected riprap gradations maximum diameter (D_{100}) value in inches. Each figure represents a riprap sizing for a given reach based on unique channel characteristics and velocities.

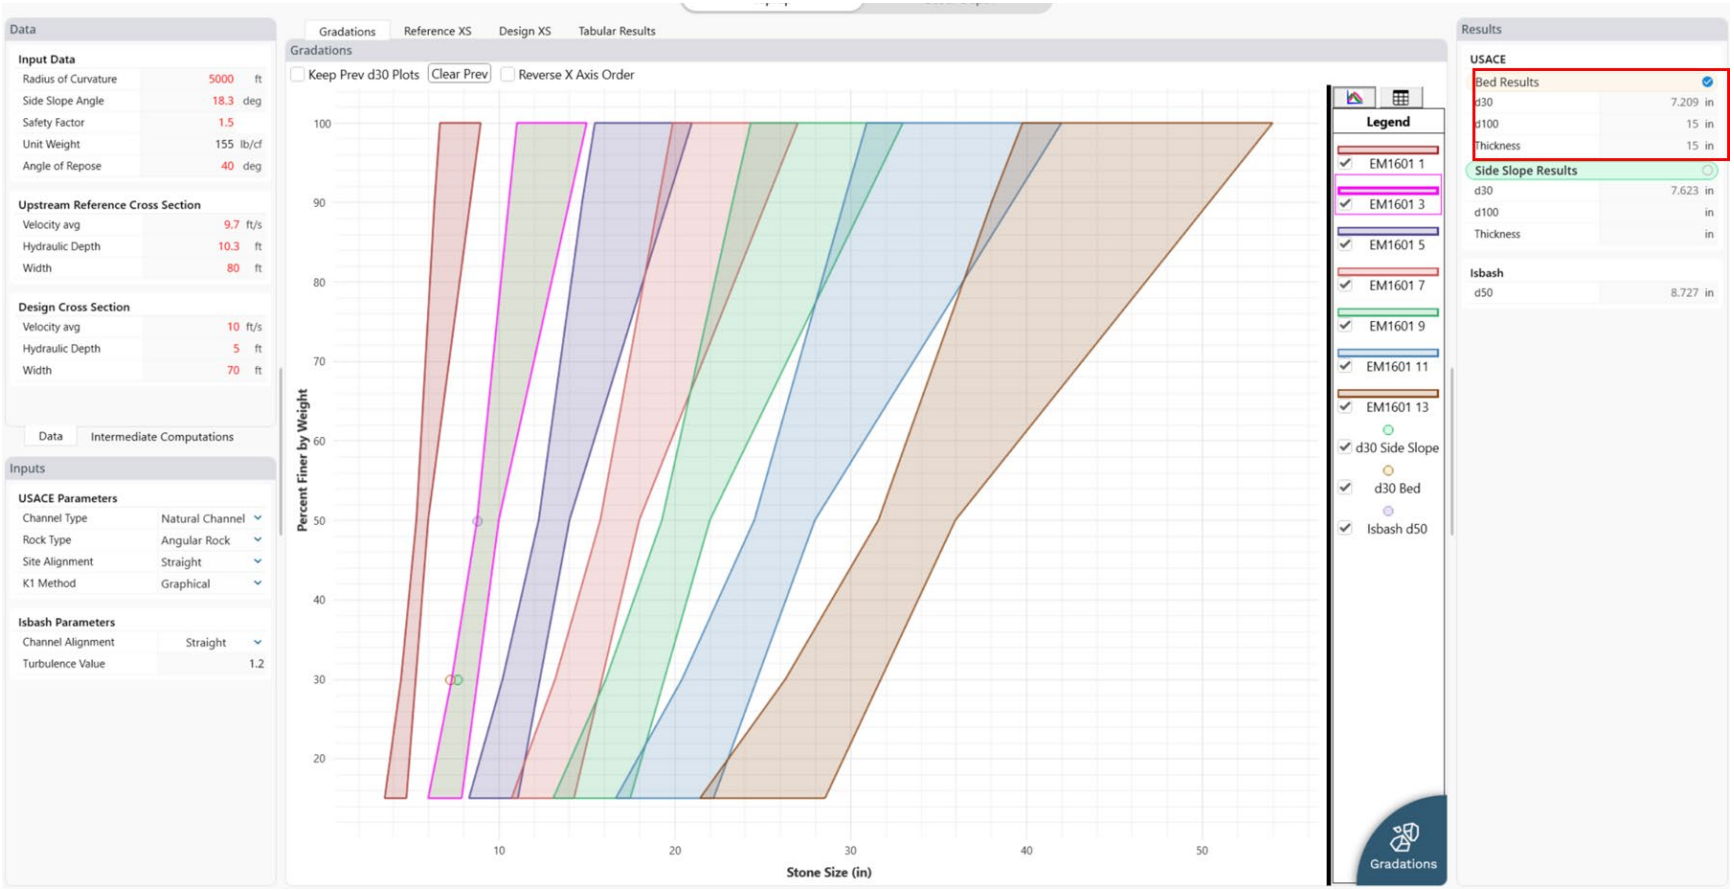
E.4.4.1 Trib (Left and Right Bank) (Channel STA 0+00-9+00)



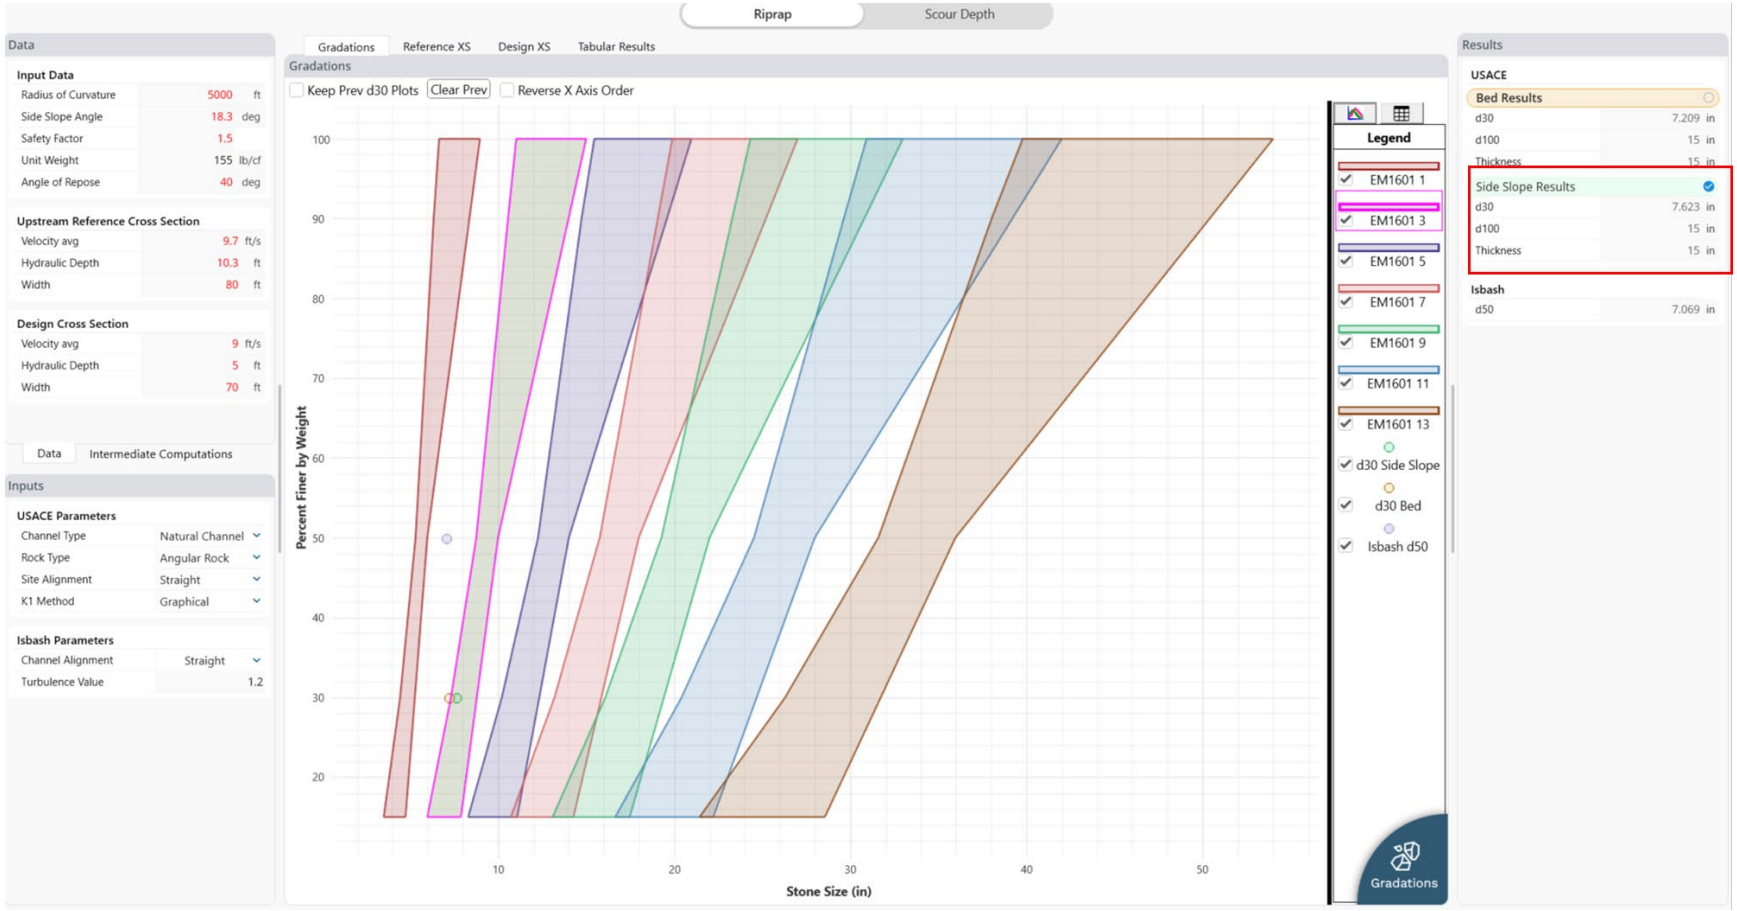
E.4.4.2 Left Bank (Channel STA 9+00-14+00)



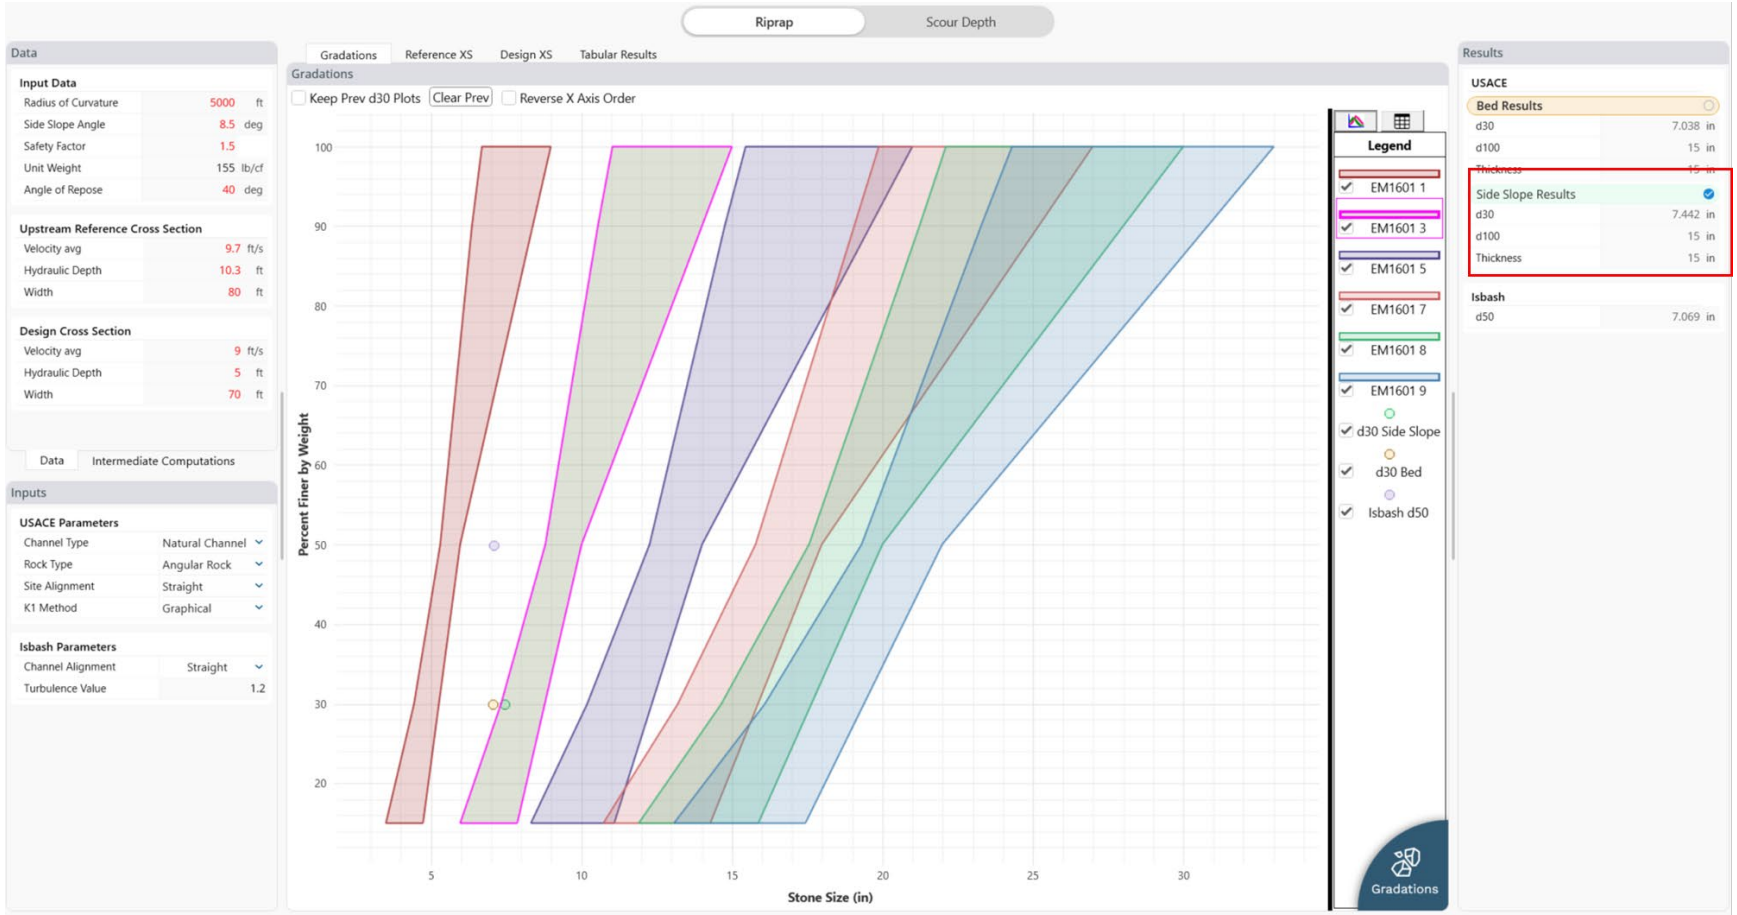
E.4.4.3 Left Bank (Channel STA 15+25-19+00)



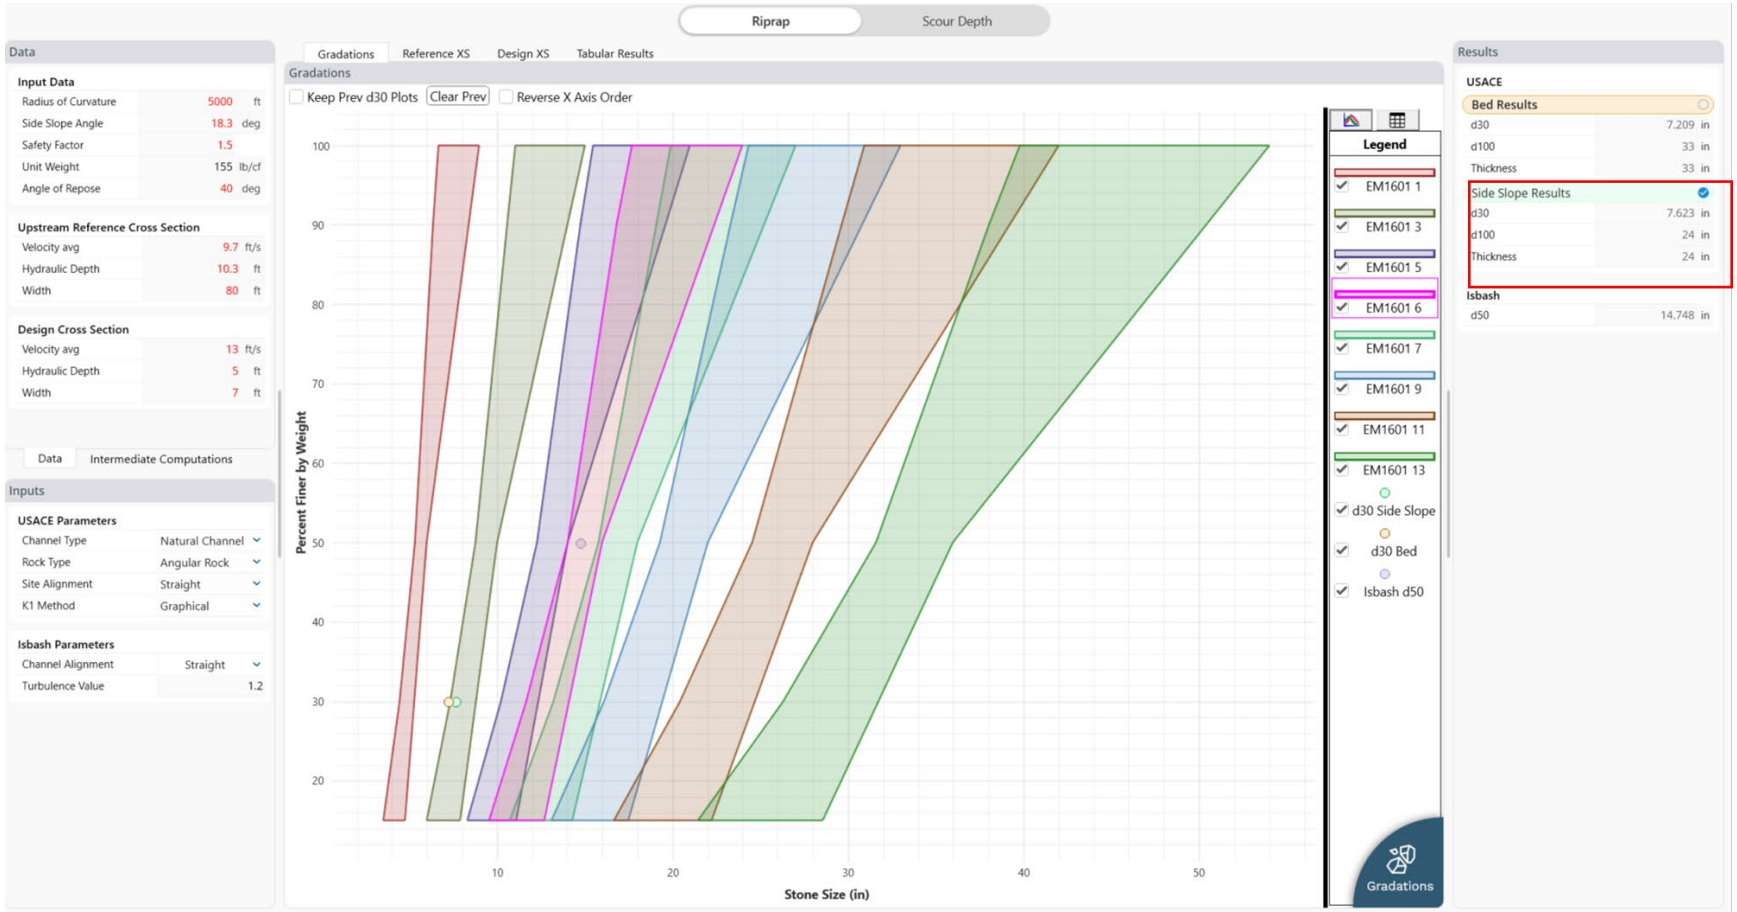
E.4.4.4 Left Bank (Channel STA 21+00-25+00)



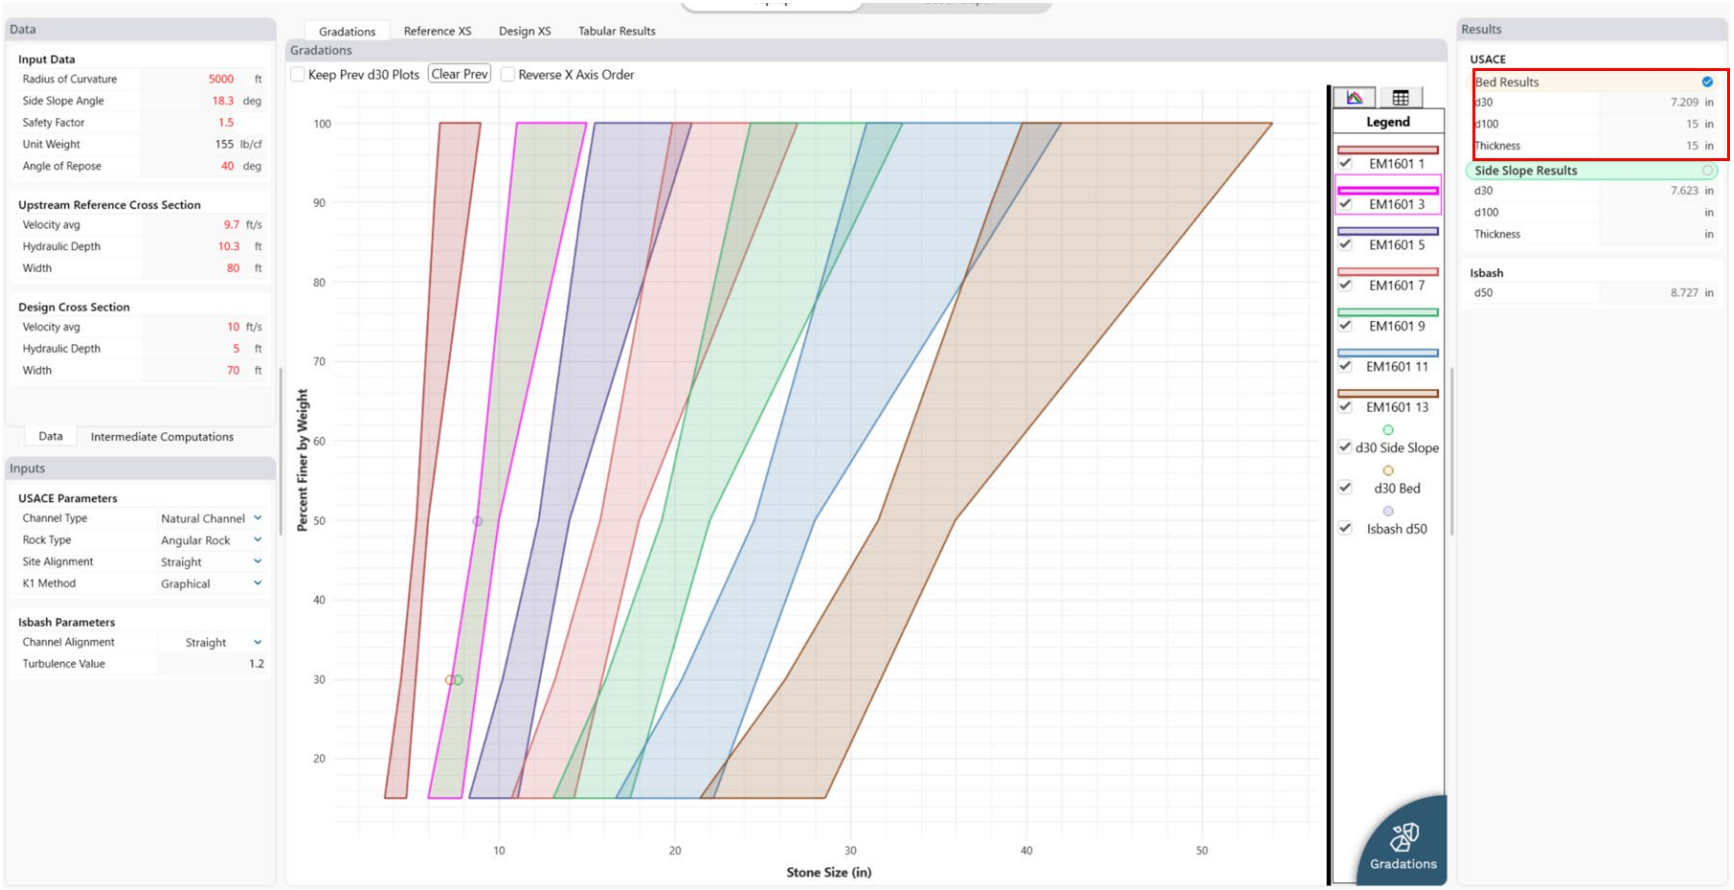
E.4.4.5 Left Bank (Channel STA 33+00-36+00)



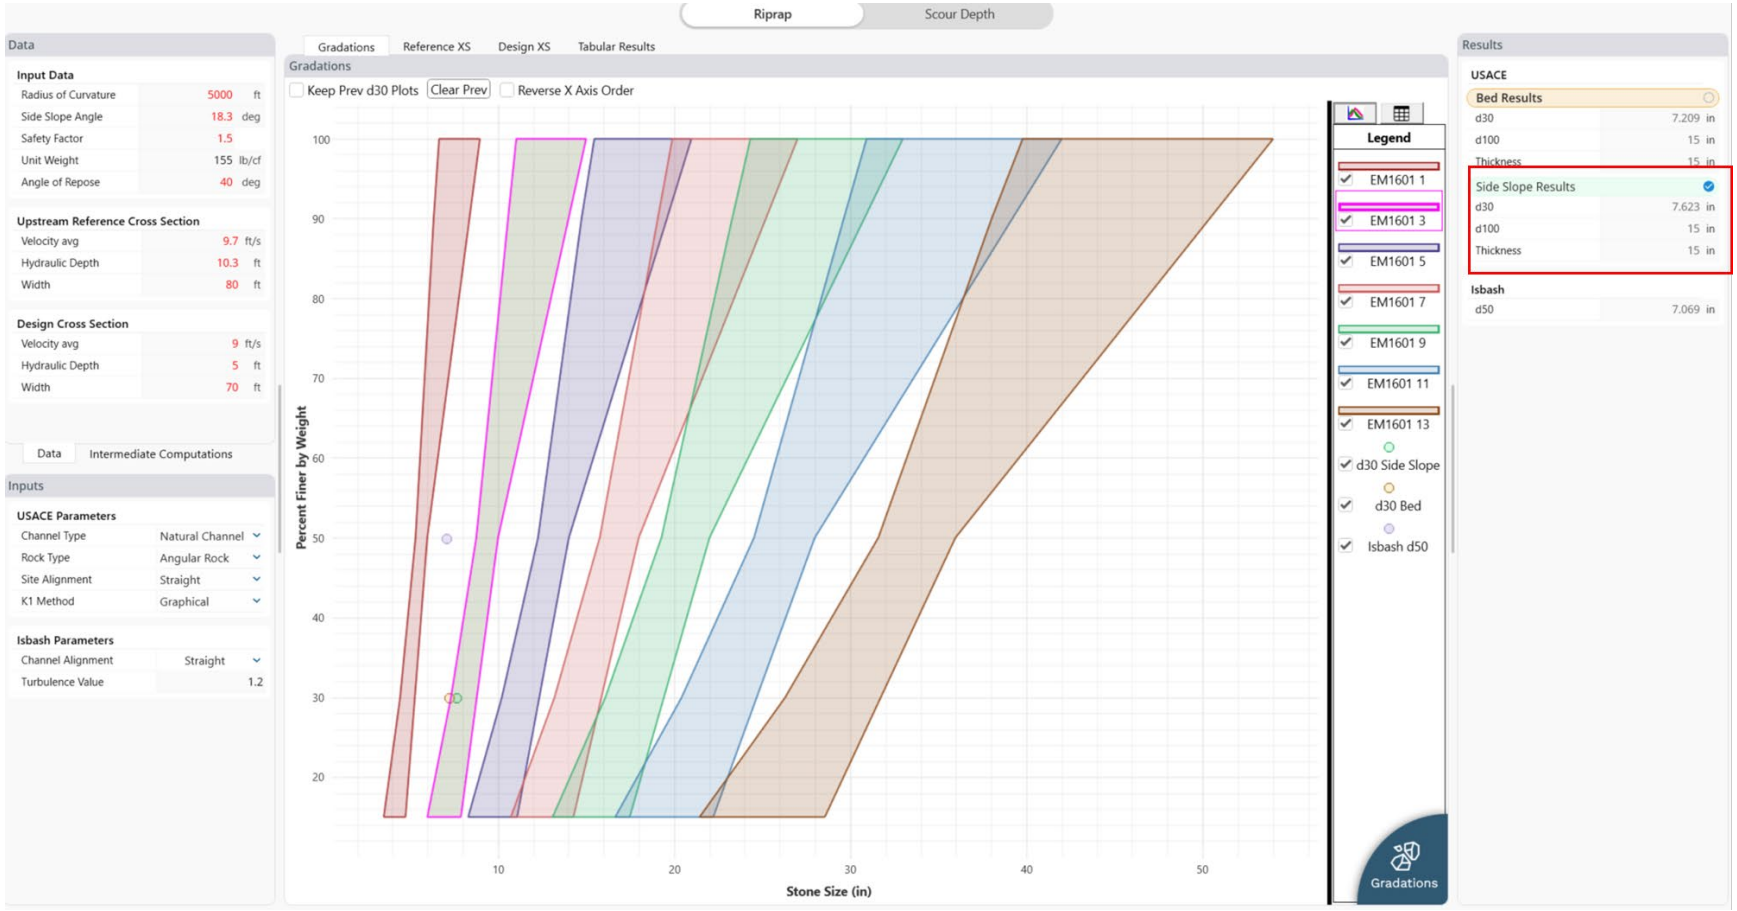
E.4.4.6 Left Bank (Channel STA 63+00-End)



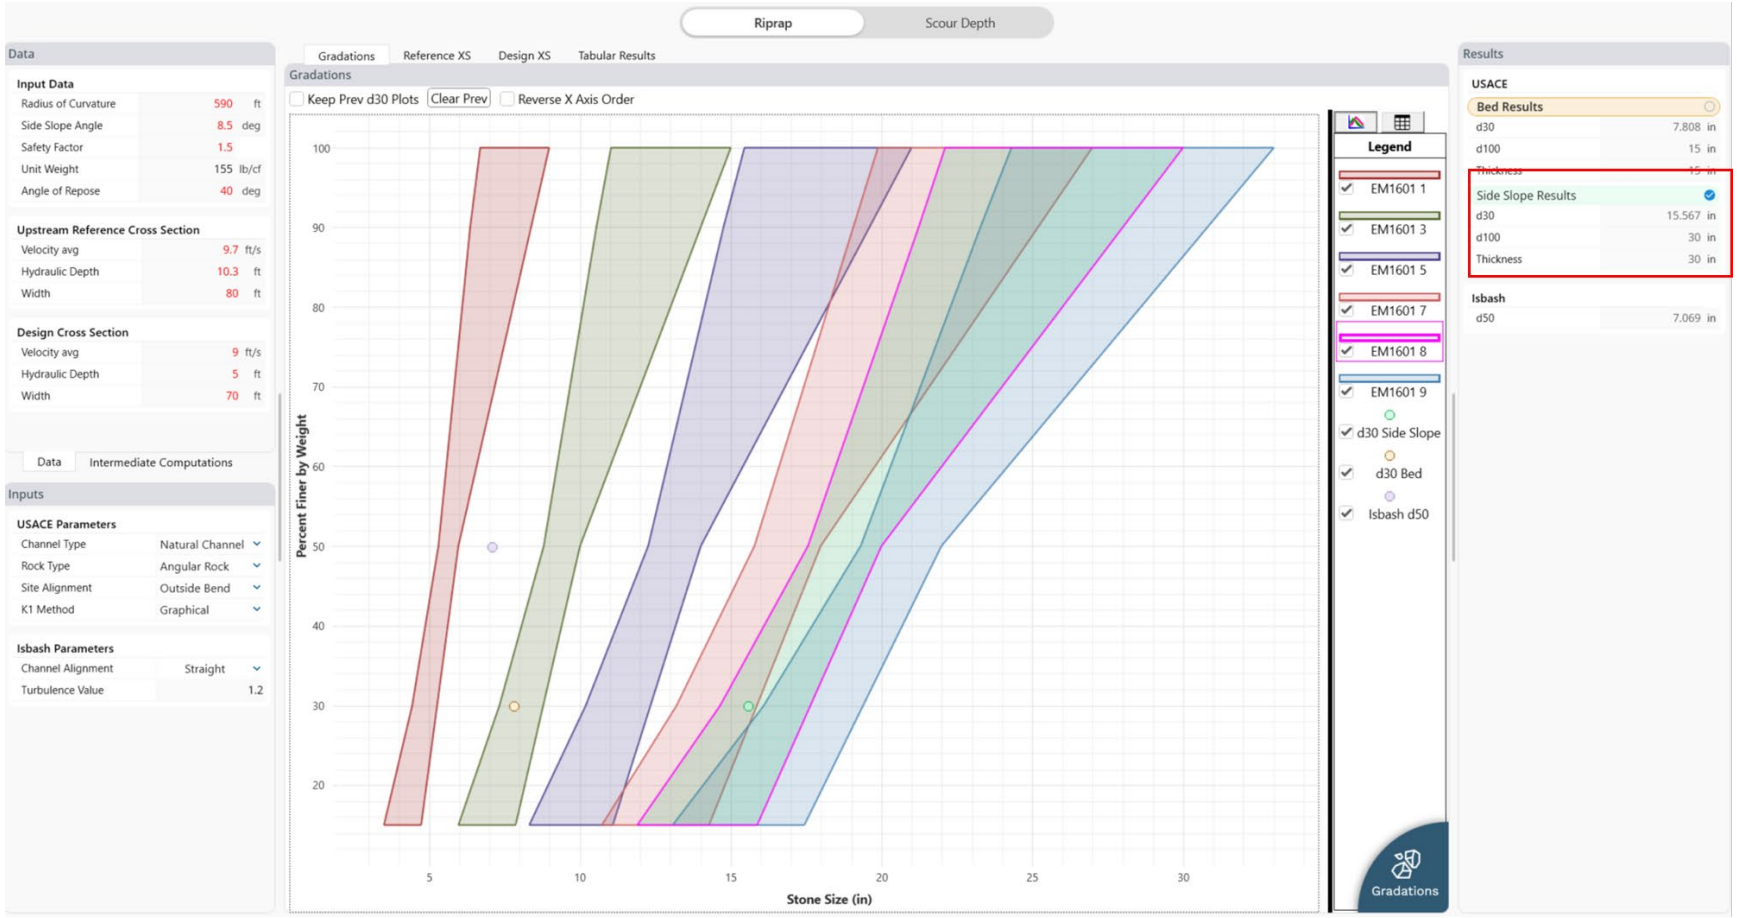
E.4.4.7 Right Bank (Channel STA 15+25-19+00)



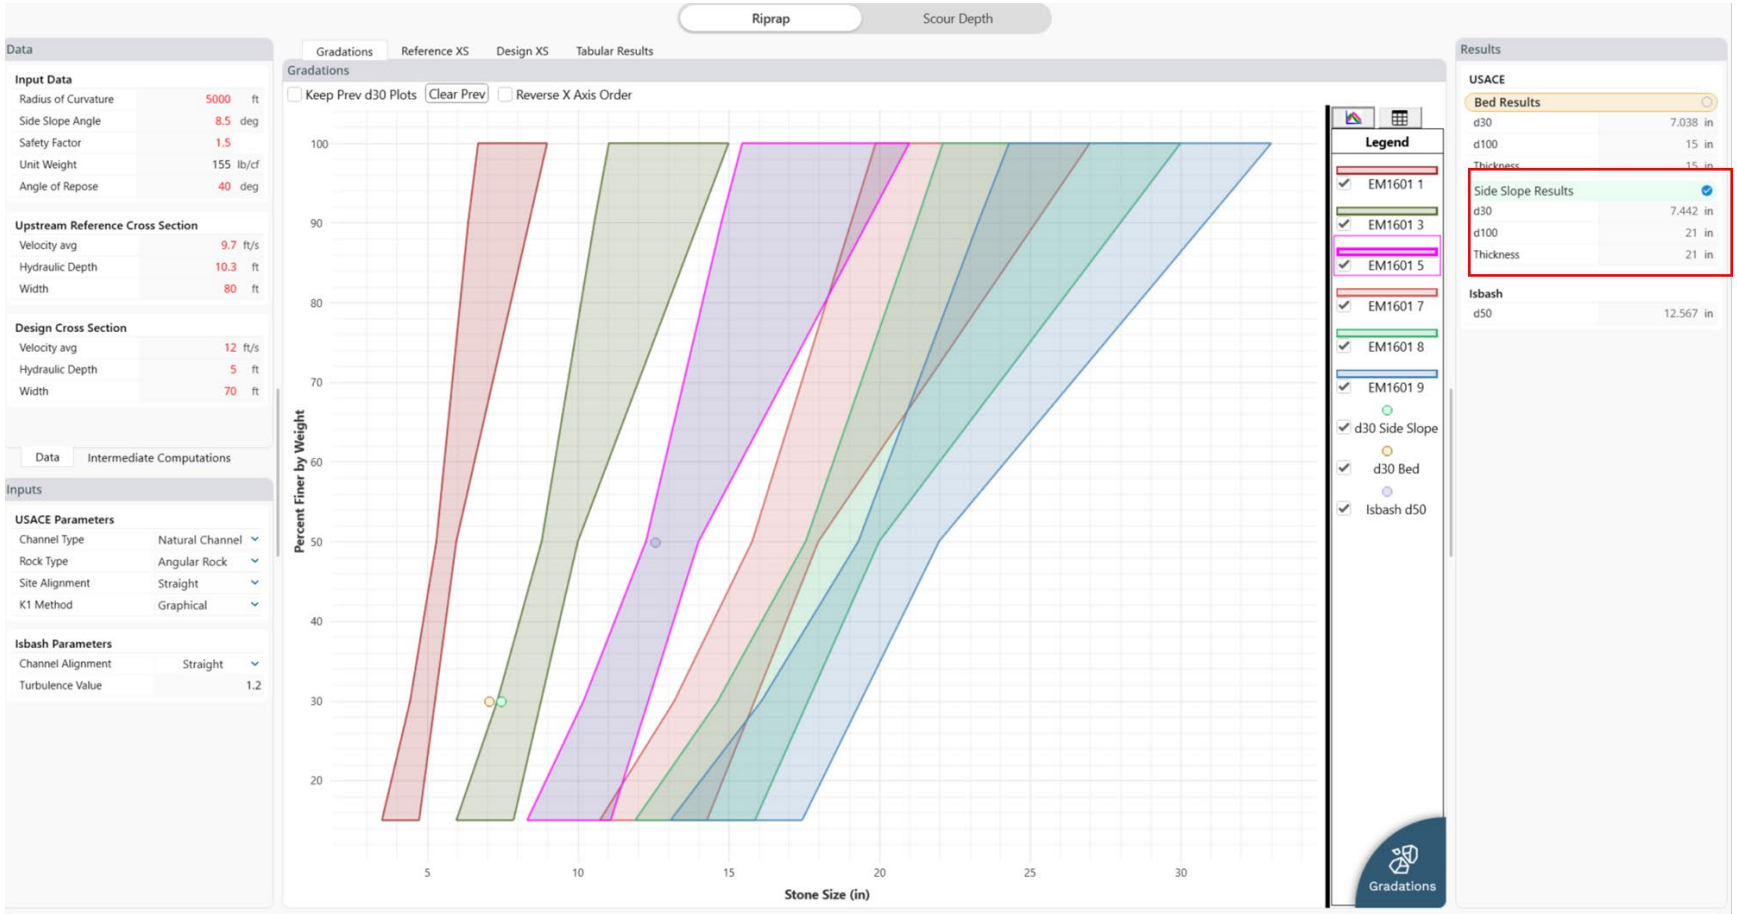
E.4.4.8 Right Bank (Channel STA 19+00-26+00)



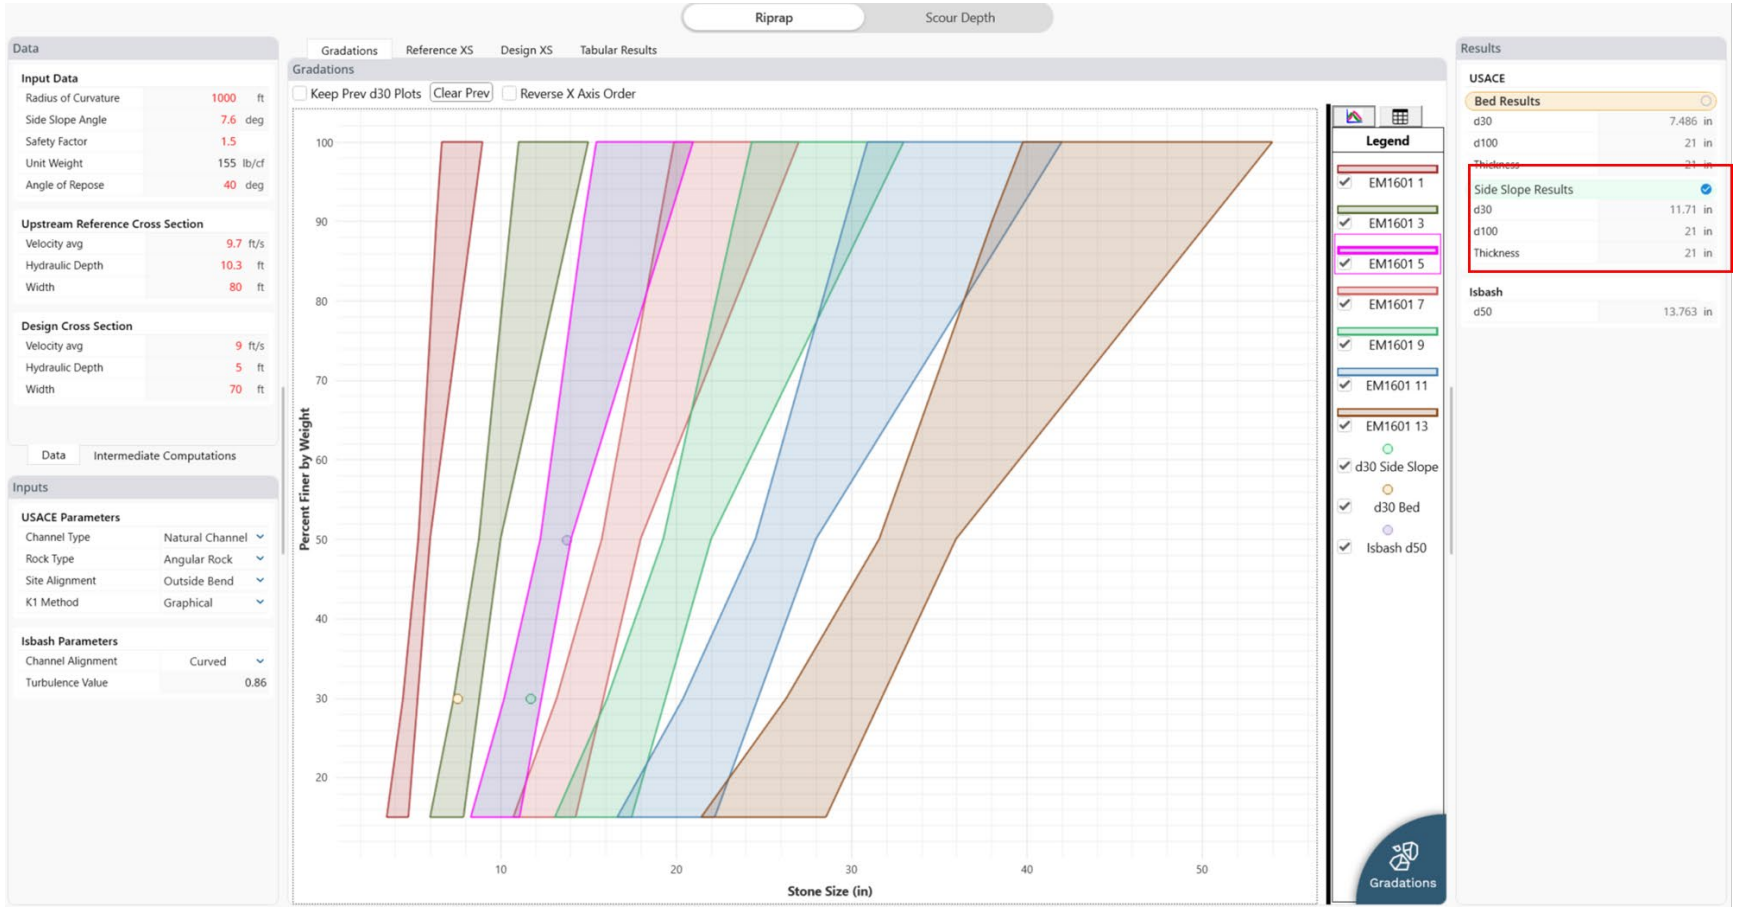
E.4.4.9 Right Bank (Channel STA 30+00-33+00)



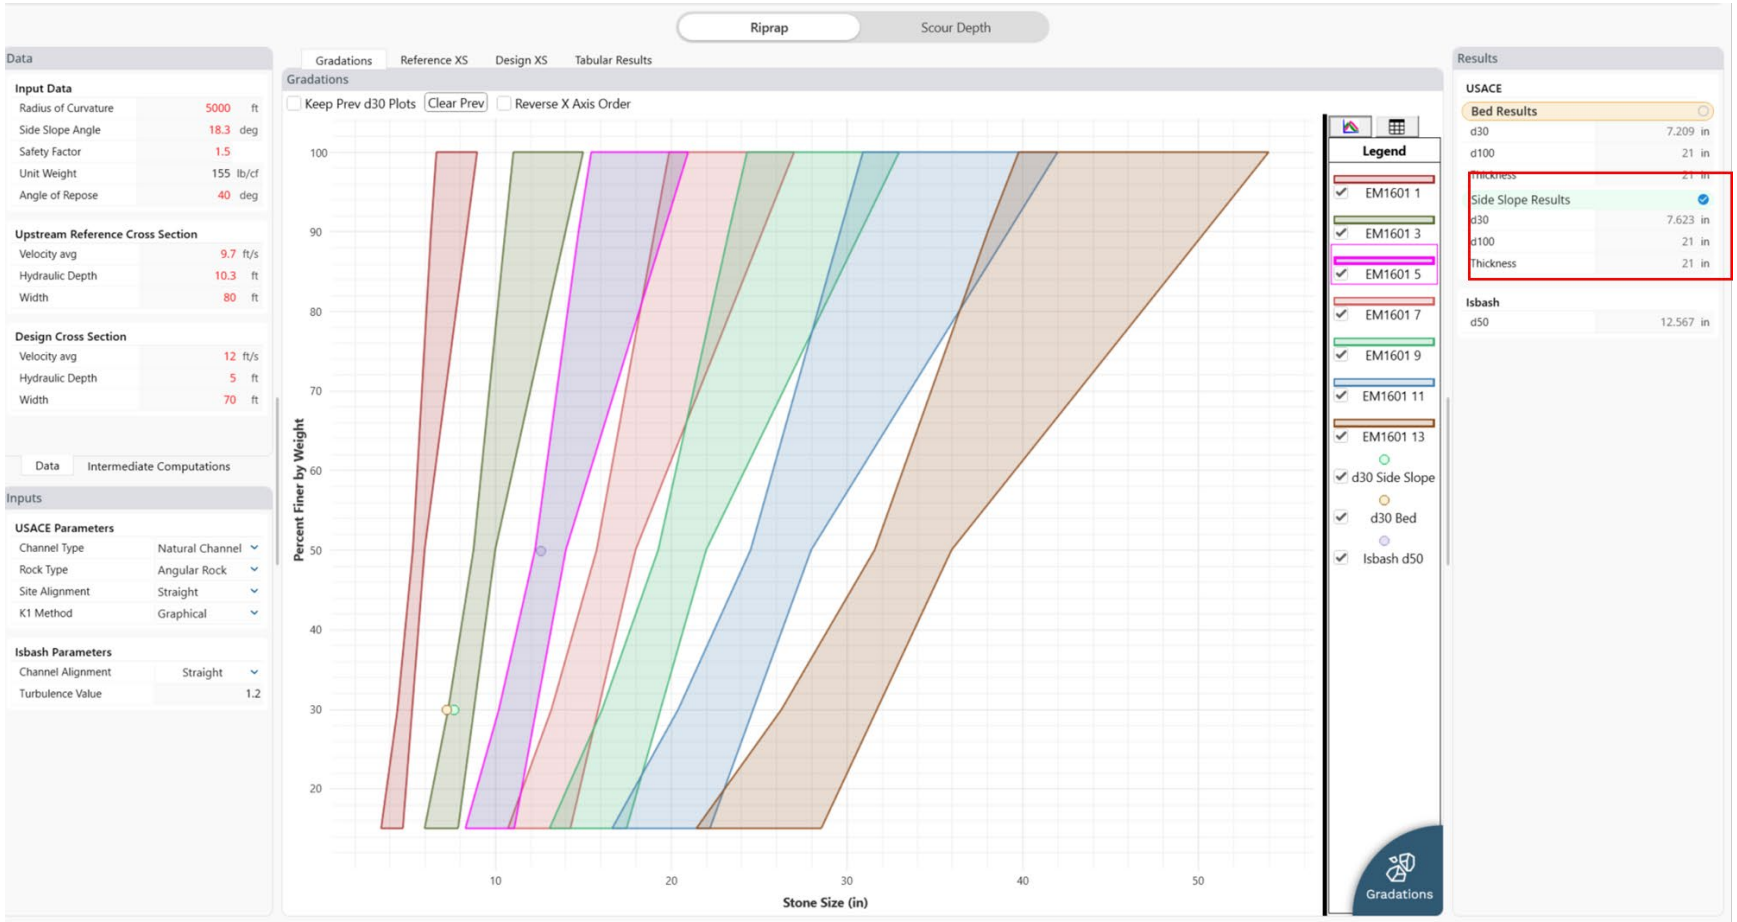
E.4.4.10 Right Bank (Channel STA 33+00-36+00)



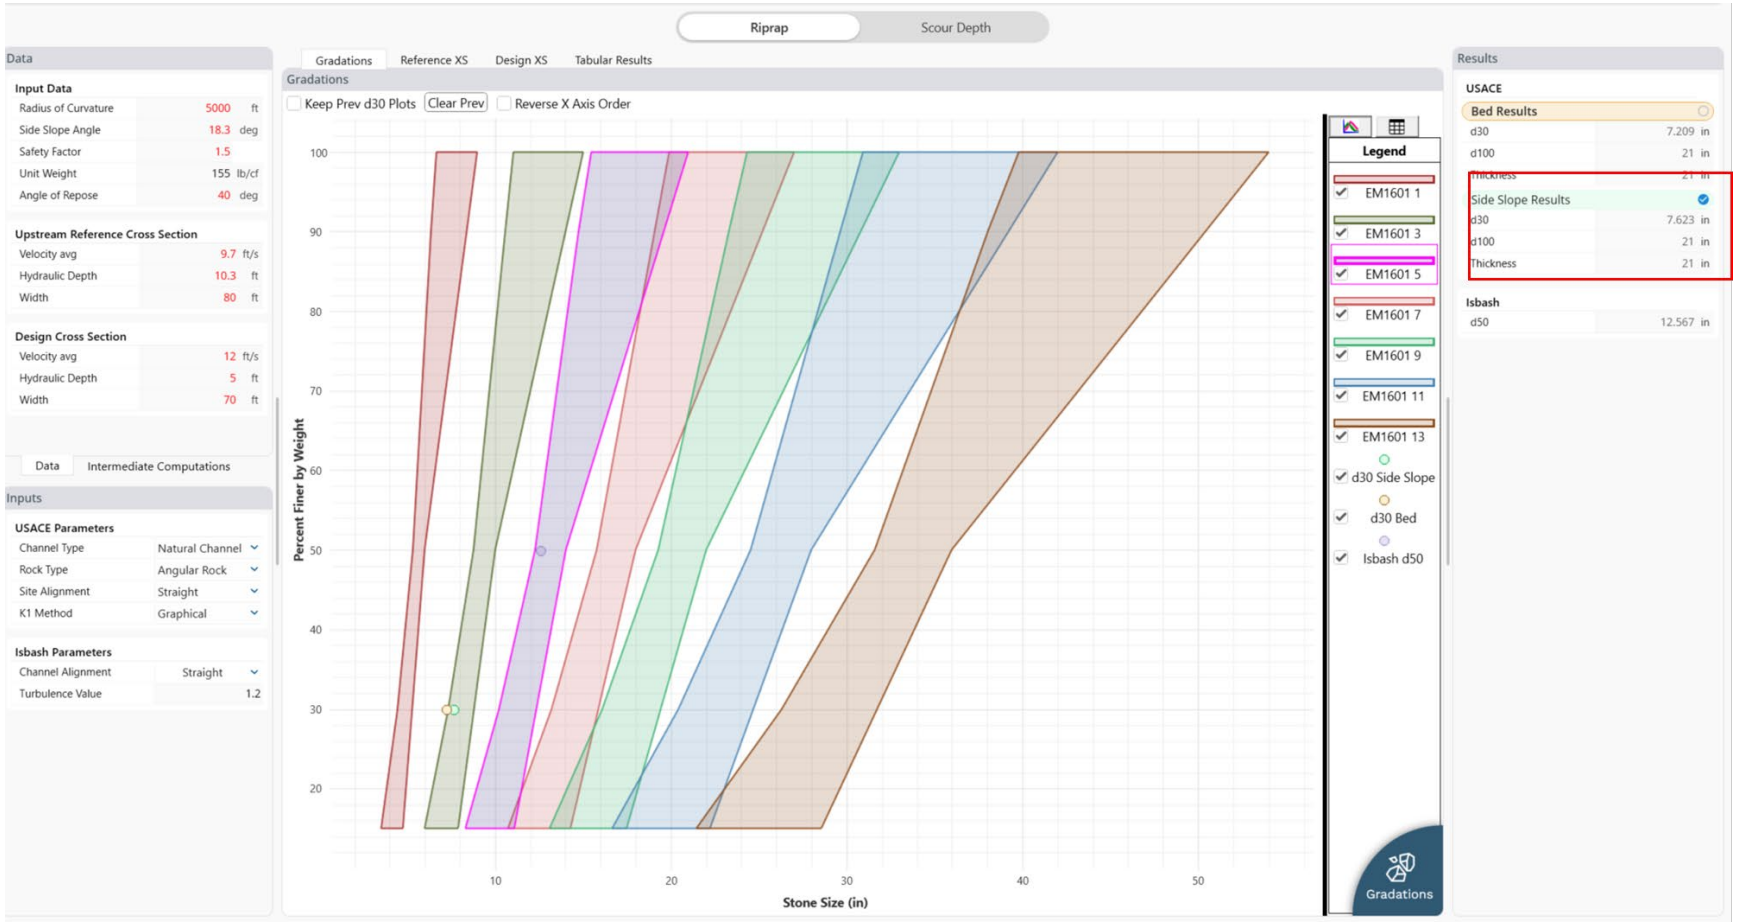
E.4.4.11 Right Bank (Channel STA 36+00-42+00)



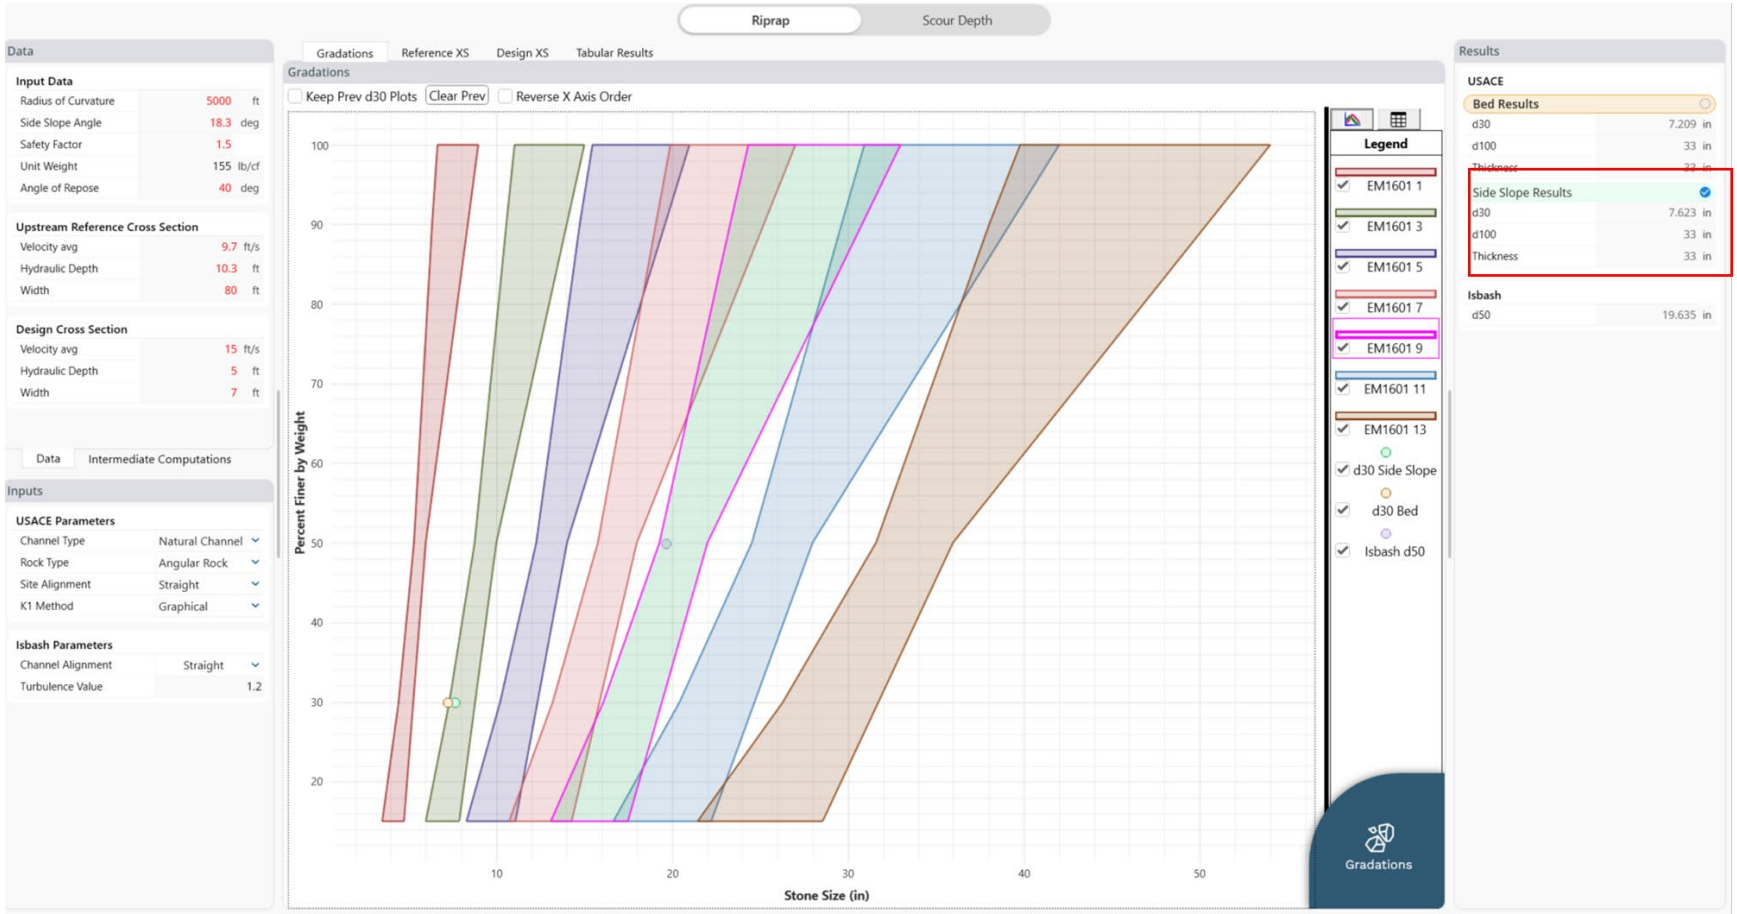
E.4.4.12 Right Bank (Channel STA 42+00-48+00)



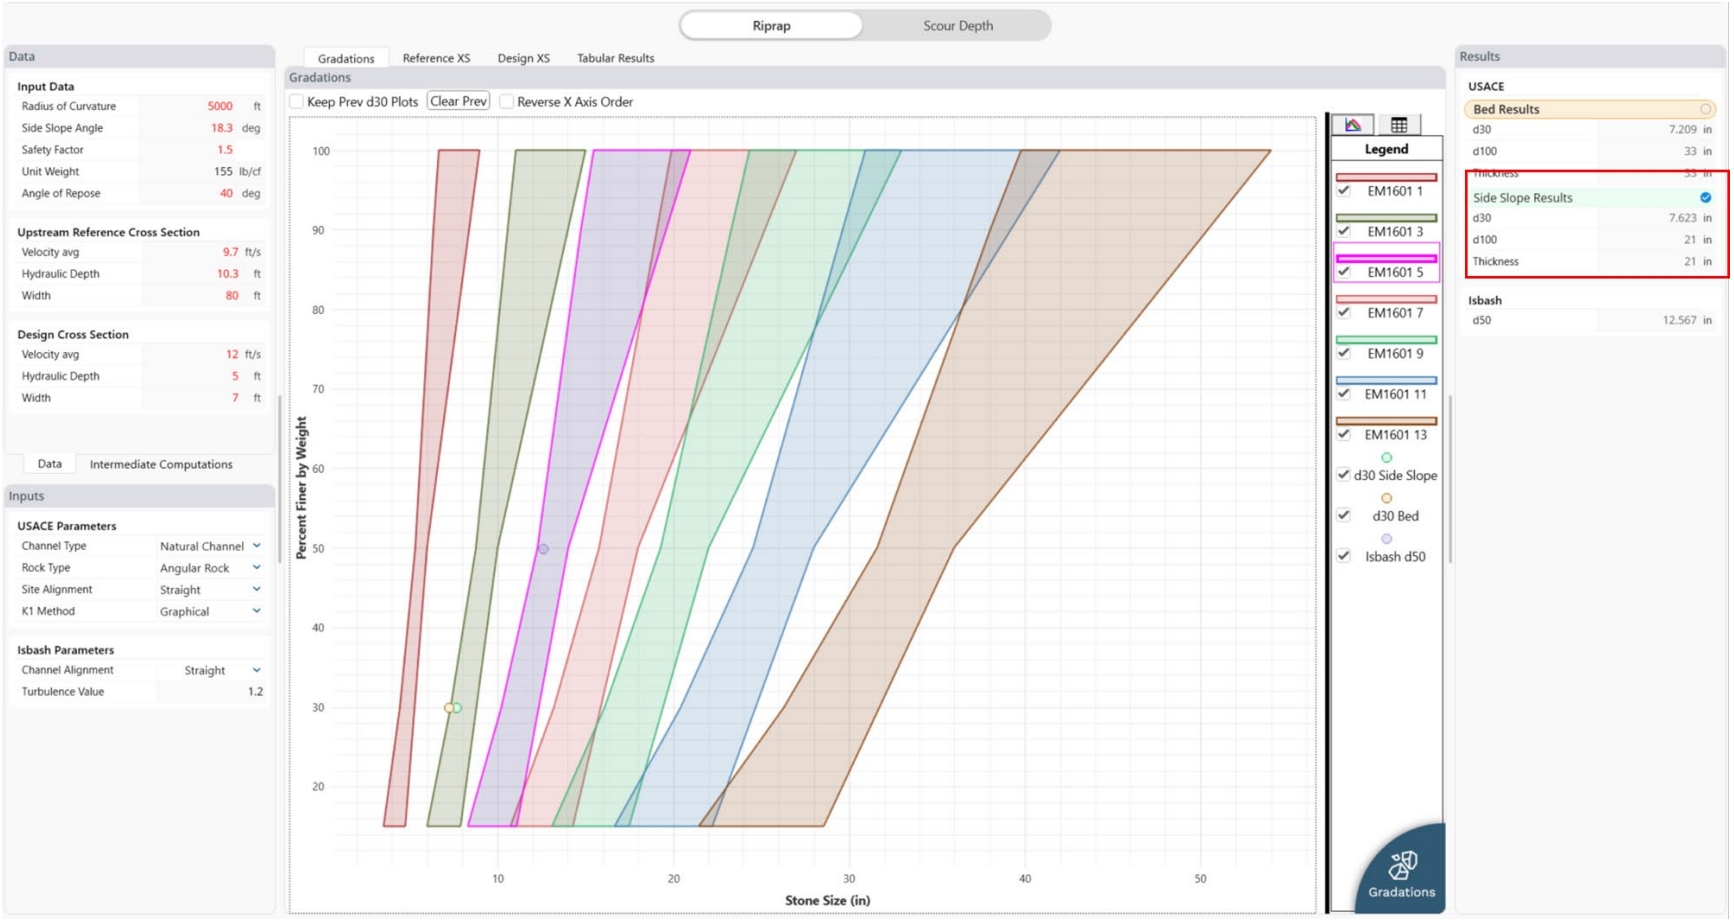
E.4.4.13 Right Bank (Channel STA 53+00-57+00)



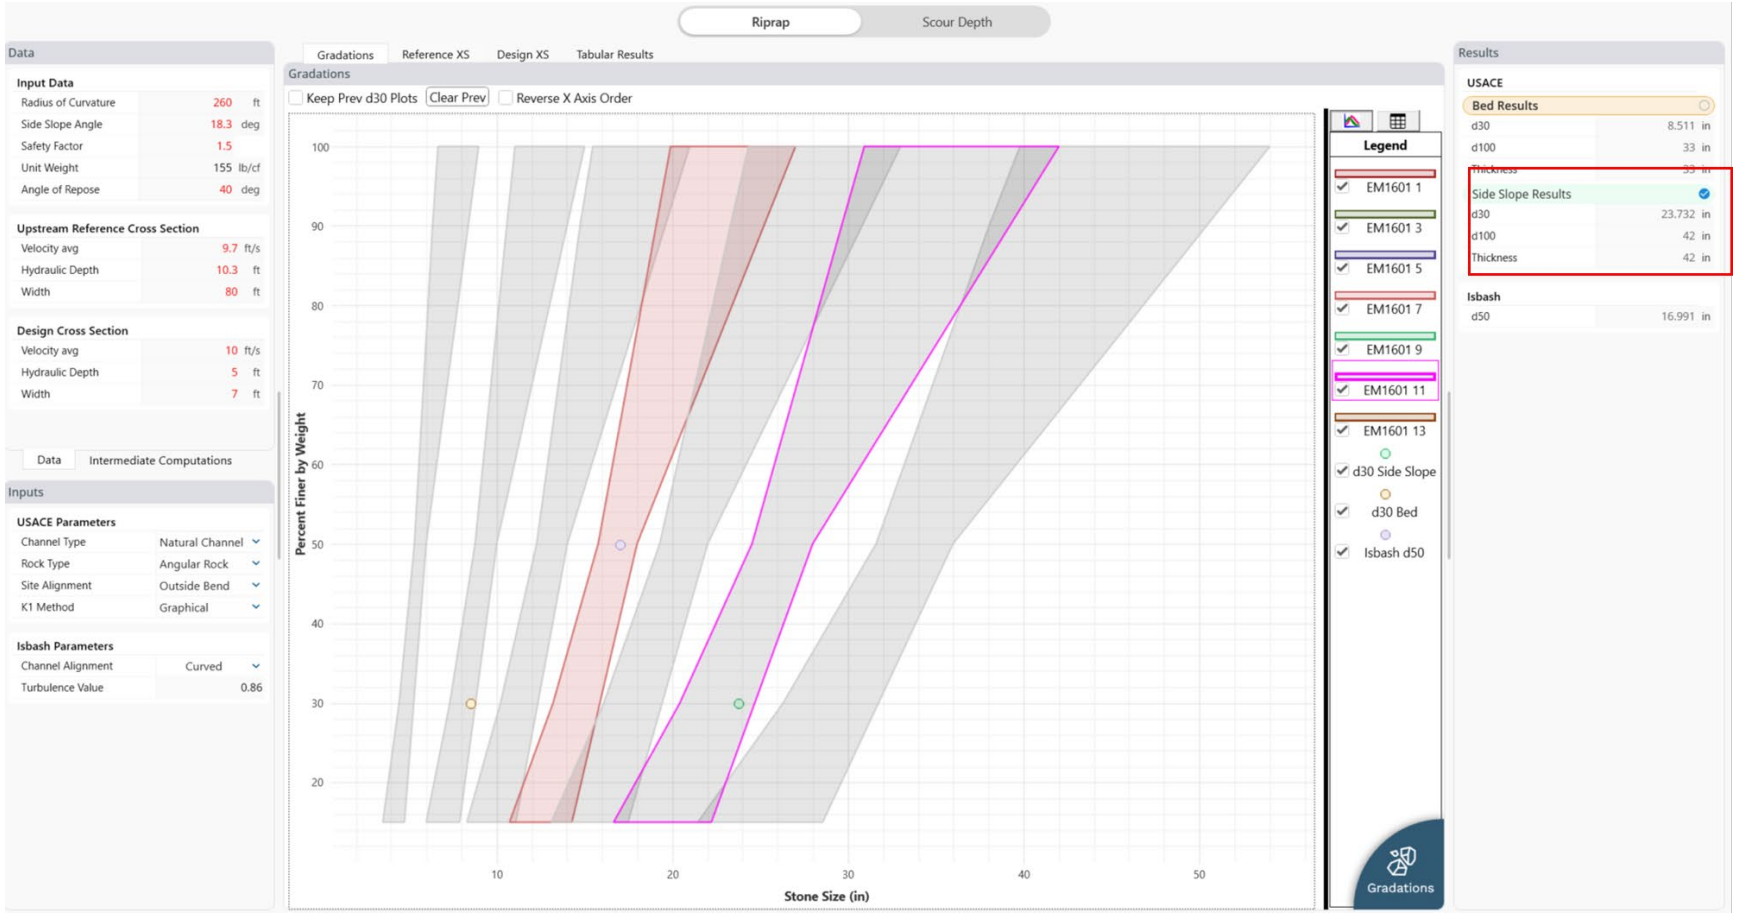
E.4.4.14 Right Bank (Channel STA 57+00-60+00)



E.4.4.15 Right Bank (Channel STA 60+00-64+00)



E.4.4.16 Right Bank (Channel STA 63+00-End)



APPENDIX E.5 – BRIDGE SCOUR H&H INPUT DATA

Introduction

Shawnee Mission Parkway Pedestrian Bridge

Merriam Market Place Pedestrian Bridge

E.5 BRIDGE SCOUR H&H INPUT DATA

E.5.1 Introduction

H&H data provided to the structural PDT member to perform a bridge scour analysis in accordance with Hydrologic Engineering Circular No. 18 – Evaluating Scour at Bridges from the Federal Highway Administration. Data was pulled to analyze the two pedestrian bridges in the project extents just downstream of Shawnee Mission Parkway and at Merriam Marketplace. Scour analyses for Johnson Drive and Merriam Drive bridges was not performed in-house as it was part of the scope for HNTB who are contracted to do the bridge designs.

Detailed hydraulic output tables were pulled from the Stantec 2D both pedestrian bridges. All results are based on the 1% AEP design event. Each bridge required 4 cross section outputs including:

- Upstream approach cross-section
- Upstream bridge face
- Downstream bridge face
- Downstream exit cross-section

E.6.1 Introduction

The following sections provides detailed model outputs not already covered in Appendices E.3 through E.5. This includes flow hydrographs at key locations and depth grids for the FWOP and with project conditions. It should be noted that the exact water surface elevations vary along the channel cross section due to superelevation, but the plots are meant to show the change between FWOP and 50% design conditions as well as the duration of high water.

1 Introduction

This report summarizes the hydrologic and hydraulic analysis for the 2-dimensional (2D) base level engineering (BLE) of Turkey Creek and Brush Creek in Johnson County, Kansas. This project includes new hydrologic and hydraulic analysis for both watersheds within the study area. The study area is shown below in Figure 1.

Table 1: Study Watershed Drainage Area

Watershed	Drainage Area (square miles)
Turkey Creek	17.1
Brush Creek	12.3

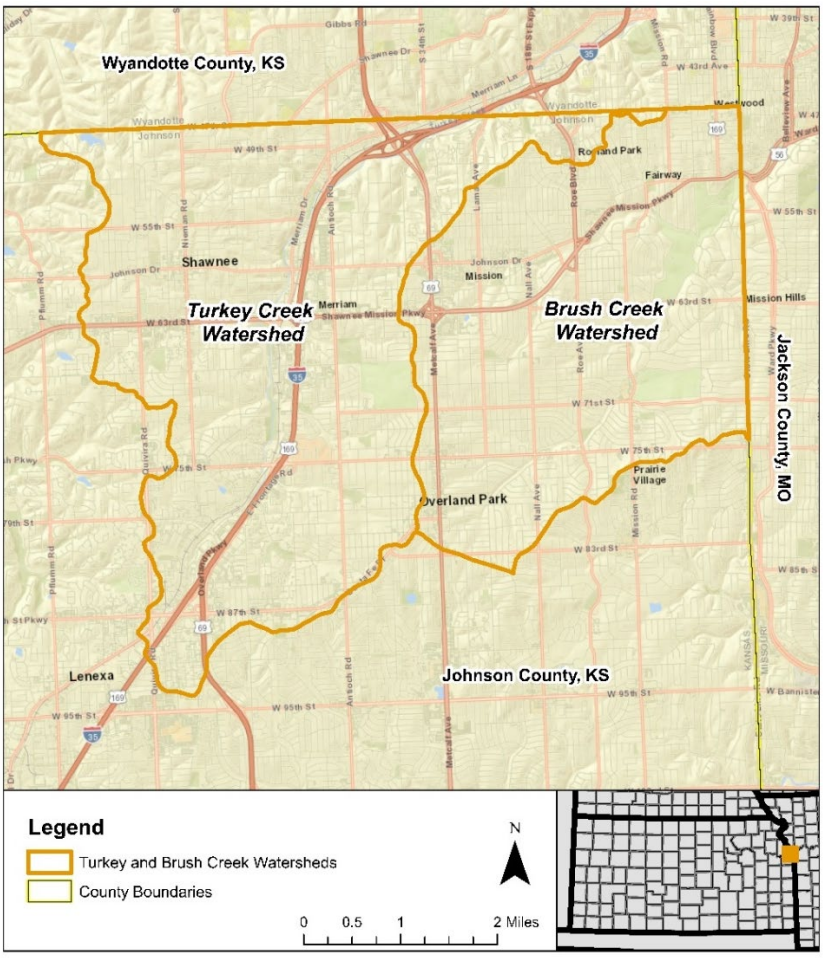

Figure 1: Turkey Creek and Brush Creek Study Area

This study includes analysis of the 50-, 10-, 4-, 2-, 1-, 1plus-, and 0.2-percent-annual-chance events. Flood hazards were identified for streams with drainage areas equal to or greater than 160 acres (0.25-square mile) or where effective floodplain mapping is present. These scoped streams match FEMA's enhanced study criteria and represent the extents where the floodplain mapping will be cutoff.

The effective hydrologic and hydraulic analysis for Turkey and Brush Creek watersheds were completed in May 2005. The hydrologic analysis was completed using HEC-1 and the hydraulic analysis was developed in HEC-RAS version 3.1.1. Floodplains were delineated based on interpolation using digital topographic maps with a contour interval of 1 foot (Reference 1). The effective floodplain mapping for Johnson County is summarized in Table 1:

Table 2: Effective Floodplain Mapping for Impacted Counties

County	Effective FEMA Floodplains
Johnson	08/03/2009

2 2D BLE Hydrologic and Hydraulic Analysis

2D models were developed for the Turkey Creek and Brush Creek watersheds to study the surface water bodies (within Johnson County) using Hydrologic Engineering Center's River Analysis System (HEC-RAS) version 6.5 (Reference 2). Both hydrologic and hydraulic calculations were developed directly in the HEC-RAS models using a rain-on-grid, 2D approach.

2.1 Hydrologic Inputs

2.1.1 PRECIPITATION DATA

As part of the Indian Creek watershed study, Johnson County funded Dr. Bruce McEnroe, a technical expert on the hydrology within Johnson County, to evaluate the appropriate precipitation and temporal distribution for the watershed studies within the County. Dr. McEnroe's study also evaluated the appropriate rainfall distribution for the flood frequency watershed analysis. Typically, a 24-hour nested hyetograph with a 12-hour peak is applied for flood frequency watershed study; however, based on Dr. McEnroe's evaluation, a 12-hour nested hyetograph with a 3-hour peak was determined as an appropriate temporal distribution for Johnson County. A copy of the final report is included as an addendum.

NOAA Atlas 14 rainfall depths vary across the County. The 1-percent annual chance 12-hour rainfall ranges from approximately 7.4 inches to 7.8 inches from west to east across the County. Johnson County concluded that a single rainfall depth derived from NOAA Atlas 14 be applied to all watershed studies in the County. Those depths were derived from KDOT's rainfall tables which are averaged by county and are summarized in Table 3.

The 1%-plus storm event is not directly provided by Atlas 14 but was calculated using the Atlas 14 provided 90% confidence interval around the baseline 1% event depth. The plus event represents the 1 standard error depth associated with the 1-percent event, and assuming a normal distribution, can be calculated as follows:

$$\sigma = \frac{X_{90} - X_{10}}{Z_{90} - Z_{10}} \quad (1)$$

$$CI_{1pctplus} = (X - \sigma, X + \sigma) \quad (2)$$

Where σ , represents the standard deviation of an assumed normal distribution around the NOAA Atlas 14 frequency estimates; X_{90} and X_{10} represent the upper and lower estimates of the 90% confidence interval, respectively; and Z_{90} and Z_{10} represent the corresponding z-scores of the upper and lower estimates. The 1-percent-plus confidence interval is approximated by applying one standard deviation above the baseline 1-percent annual chance event. The average 90% and average 10% confidence interval depths for the County were used to estimate the 1% plus rainfall depth.

Table 3: 12-hour Duration Rainfall Depths for Johnson County, Kansas

	Annual Chance Exceedance Event						
	50%	10%	4%	2%	1%	1%+	0.2%
12-hr Rainfall Depth (in)	3.17	4.74	5.82	6.71	7.65	8.56	10.04

The nested distributions and corresponding hyetographs were developed based on the County-wide average rainfall depths and are shown in Figure 2 and Figure 3.

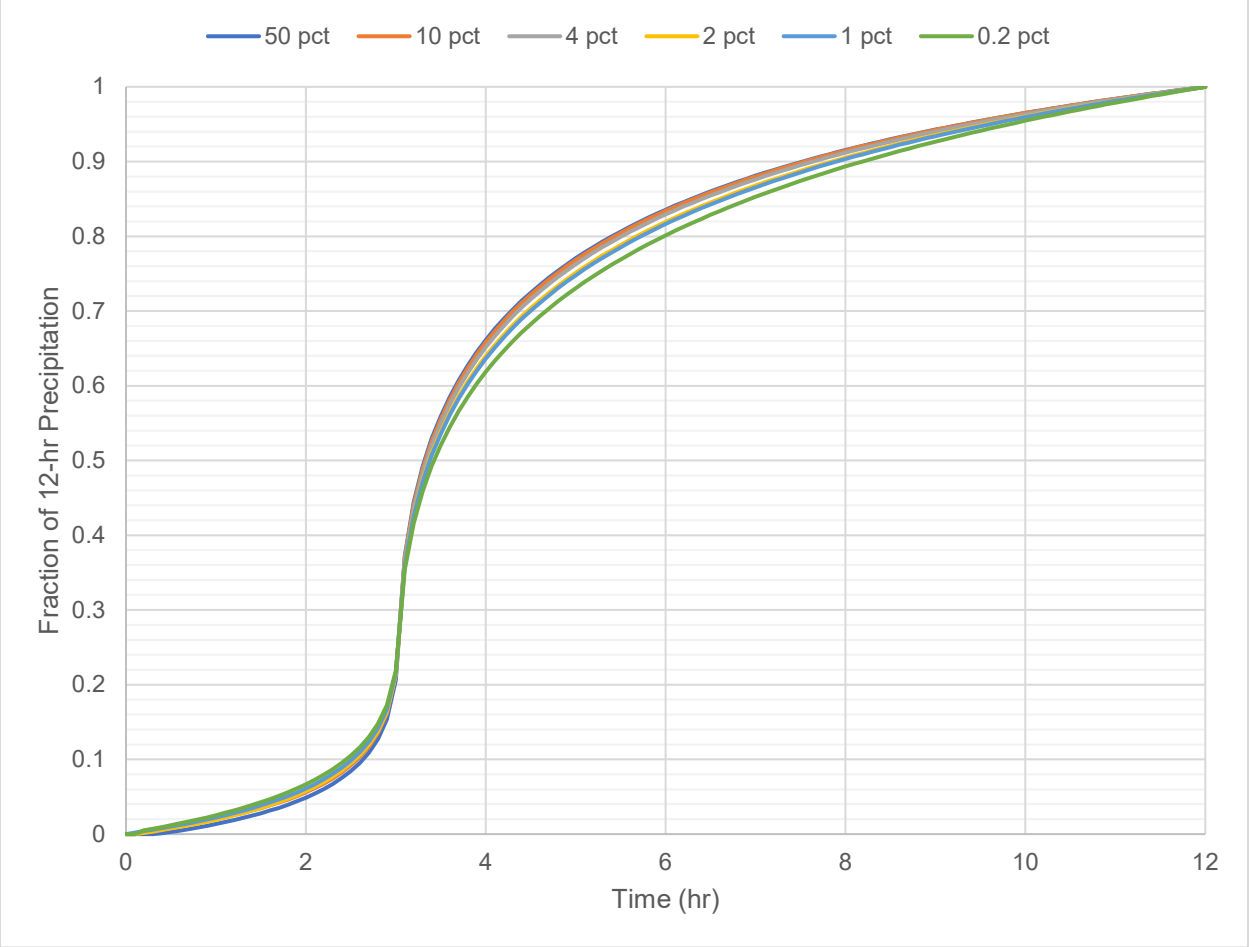

Figure 2: 12-hour Storm, 3-hour Peak Nested Distribution

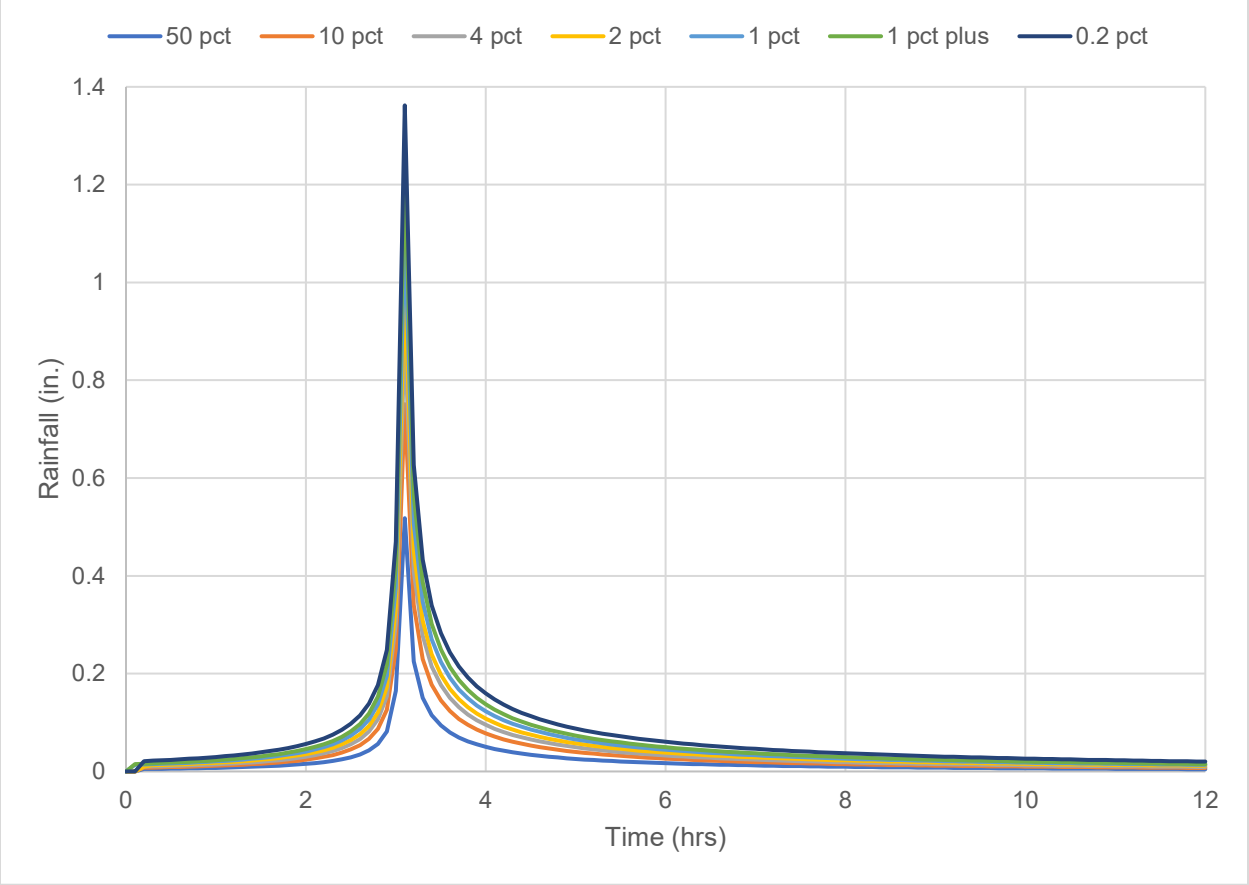

Figure 3: Rainfall Hyetograph for 12-hour Storm with 3-hr Peak

2.1.2 INFILTRATION

Hydrologic calculations were applied directly in HEC-RAS using the Soil Conservation Service (SCS) Curve Number (CN) method. Base CN data was developed using 2021 aerial imagery from Johnson County, Automated Information Mapping System (AIMS) datasets that include roadway, trees, channels (natural and concrete) and SSURGO Soil Data. One soil group within the study area did not have a hydrologic soil group defined (Urban land-Harvester complex, 2 to 9 percent slopes). In upland areas where adjacent soils were C, a soil type C was applied. For the areas with no defined soil group along Highway 69 and Interstate 635, a soil group type D was applied. One dual soil group was present in the Turkey Creek watershed (C/D); the lower of the two soil groups, D, was applied for the CN application. The dominant soil groups in the Turkey and Brush Creek watersheds are groups C and D. The base curve numbers were derived from the NRCS TR-55 document (Reference 6) and are consistent with the base curve numbers applied in the Indian Creek watershed study that was previously modeled in Johnson County (Reference 5).

Table 4: Base Curve Numbers for Turkey Creek and Brush Creek Study Area

Description	A	B	C	D
Open Water	100	100	100	100
Barren Land	76	85	90	93
Buildings	98	98	98	98
Grass	39	61	74	80
Pavement	98	98	98	98
Trees	36	60	73	79
Concrete Channel	98	98	98	98
Natural Channel	39	61	74	80

2.1.3 DOMAIN DEVELOPMENT

The northeast (NE) corner of Johnson County includes Turkey Creek and Brush Creek for the 2D modeling. The domains were based roughly on the National Hydrography Dataset (NHD) HUC12 watershed boundaries and were developed with 500-foot buffer to ensure all the contributing drainage area is captured in the flow routing based on the terrain data for the County. Each watershed domain was also extended approximate 1-mile downstream of the County boundary to ensure the downstream boundary condition does not directly impact the water surface elevations along the study streams.

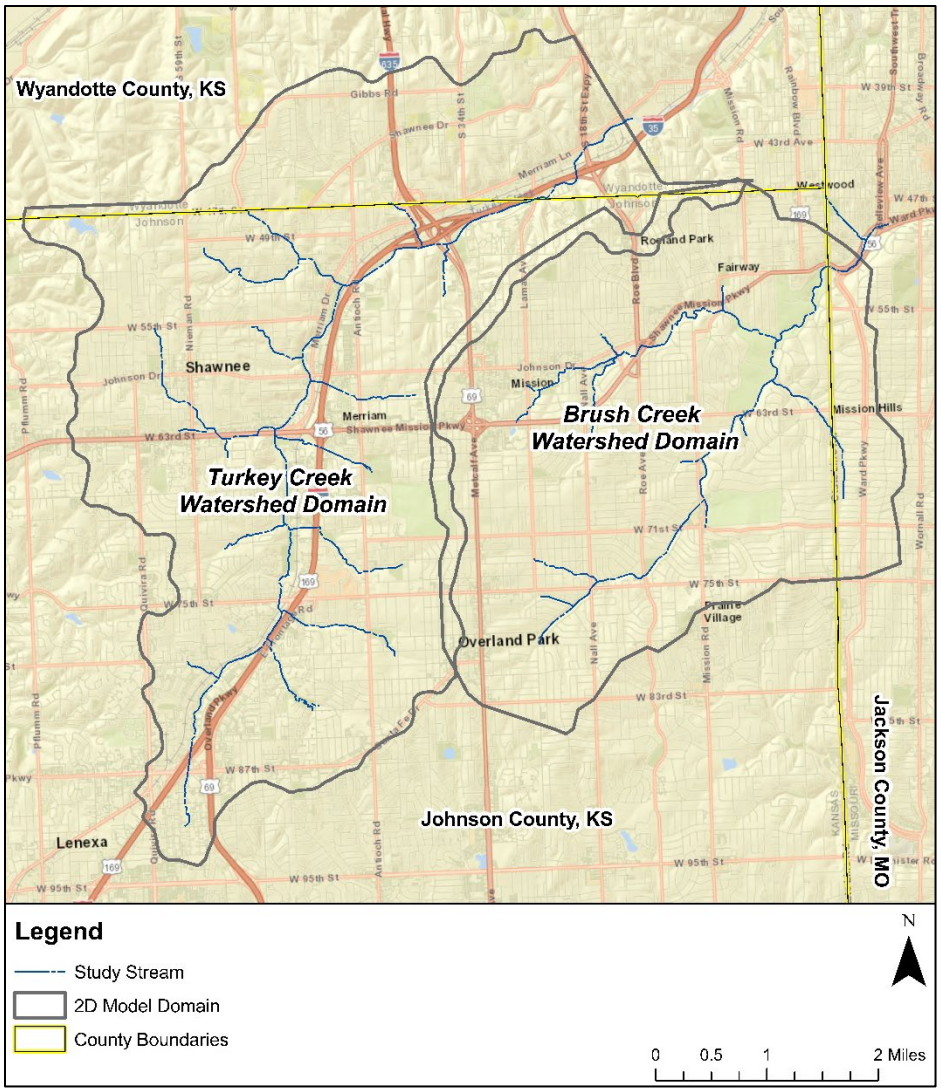

Figure 4: Turkey Creek and Brush Creek HEC-RAS Domains

2.1.4 TERRAIN DATA

Terrain data was provided by Johnson County through the Automated Information Mapping System (AIMS) for Turkey Creek and Brush Creek (2-ft resolution). The LiDAR was flown in December of 2020. For the portion of Turkey Creek that is outside of Johnson County, located in Wyandotte County, supplemental LiDAR was downloaded from Kansas' Data Access and Support Center (DASC) at 1-meter resolution. The LiDAR acquired from DASC was collected in 2018. The DASC LiDAR was reprocessed to match the resolution of the Johnson County LiDAR and were mosaicked together. Figure 5 below identifies the areal portion of the model that relies on DASC terrain data. A small portion of the Brush Creek watershed, within Jackson County, Missouri was obtained from the Missouri Spatial Data Information Service (MSDIS) to ensure the terrain covered the entire drainage area of Brush Creek. The MSDIS LiDAR has a 1-meter resolution and was acquired in 2006.

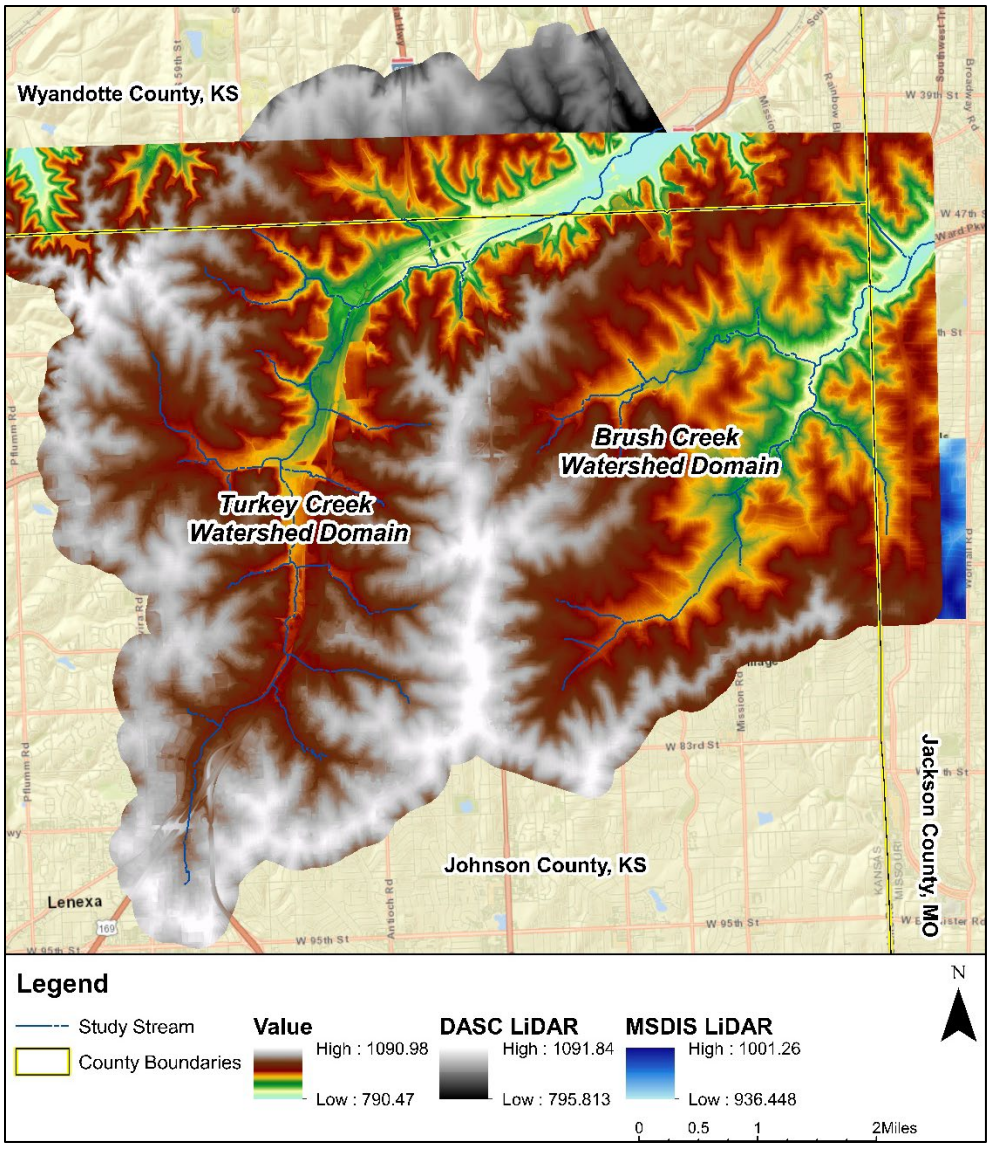

Figure 5: DASC and MSDIS Terrain Supplemented with AIMS for the Turkey Creek Watershed

2.1.5 SURVEY

Survey of bridges, culverts, and channel cross-sections were taken in the field by Renaissance Infrastructure Consulting (RIC) between January and March 2023. All structures along the study streams were surveyed and incorporated into the models as 2D connections. Survey locations are shown in Figure 6.

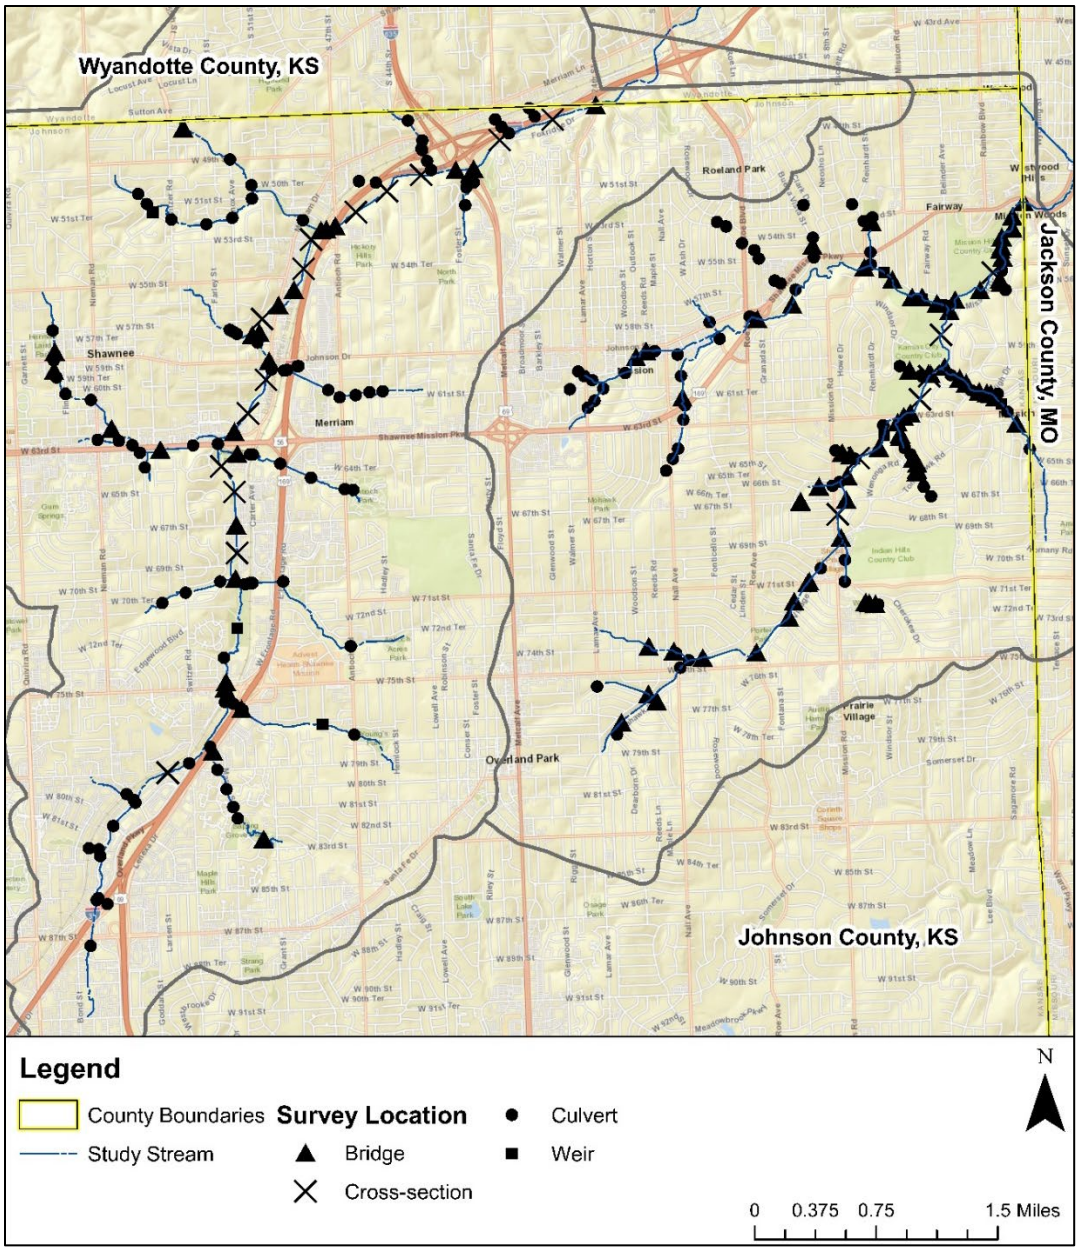

Figure 6: Turkey and Brush Creek Survey Locations

Cross-sectional channel survey was collected along Turkey and Brush Creeks. This channel bathymetry was burned into the terrain where differences in survey and LiDAR indicated that the LiDAR was not capturing the true channel bottom. The channel survey was interpolated and merged with the LiDAR to account for the additional conveyance not captured in the LiDAR. For Turkey Creek, surveyed cross-section locations showed little to no difference between the surveyed elevations and the LiDAR suggesting that the LiDAR was flow during a low-flow condition in the channel and adequately captures the channel conveyance. The survey was incorporated into the final 2D model terrain, interpolating

between survey locations and retaining only survey locations where the hydro-flatted LiDAR was higher than the survey.

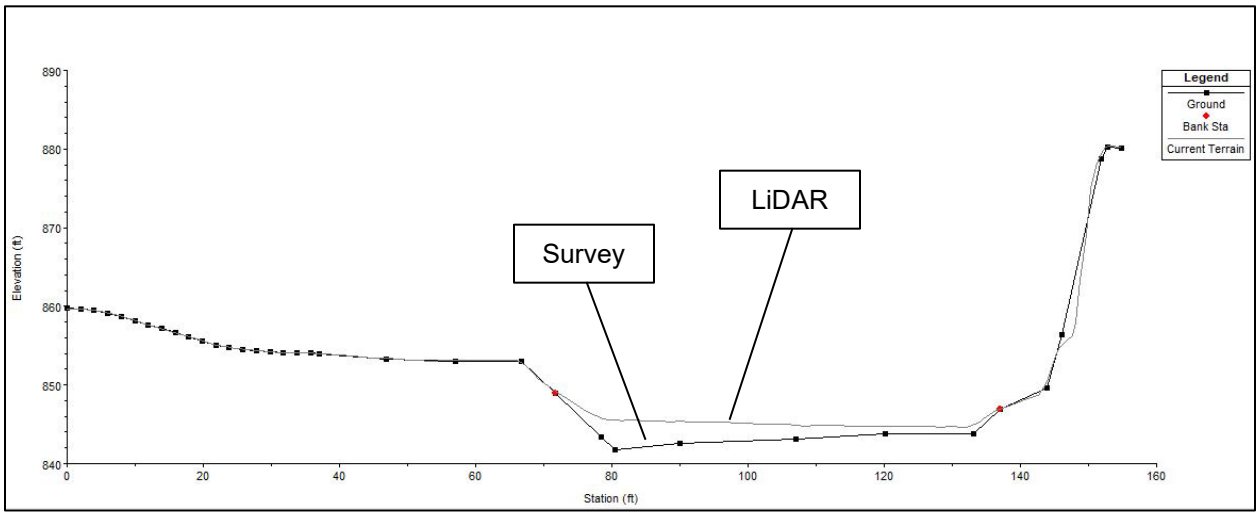

Figure 7: Turkey Creek Survey XS versus LiDAR near 635

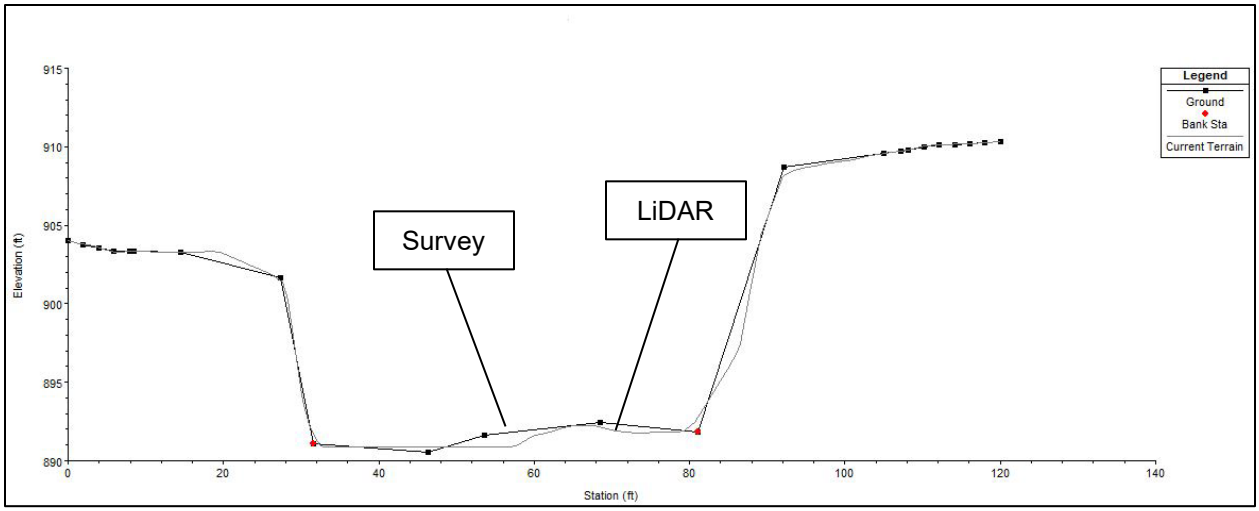

Figure 8: Turkey Creek Survey XS versus LiDAR near Johnson Drive

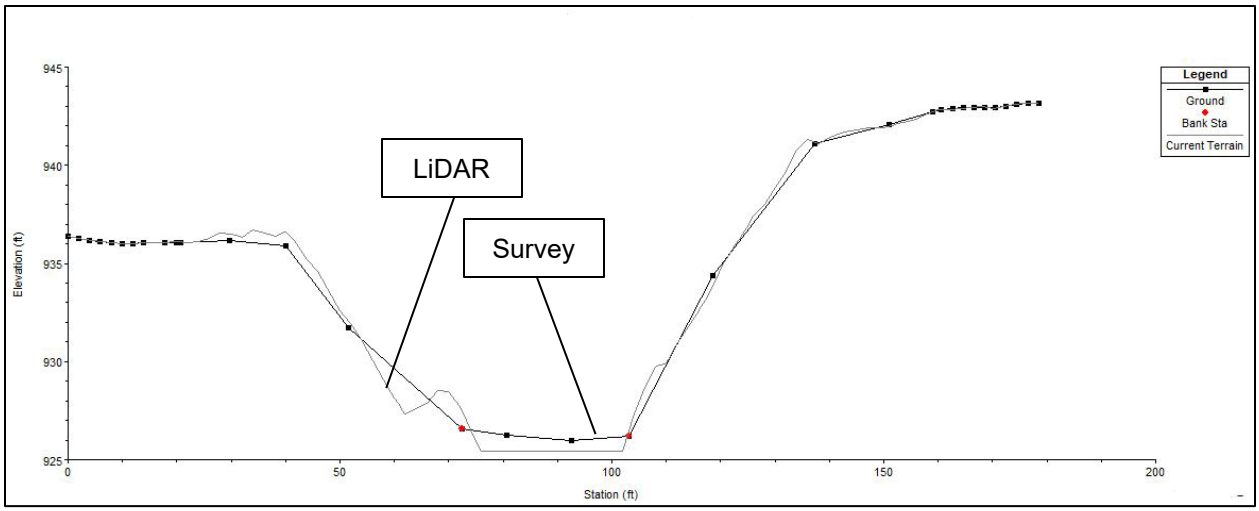

Figure 9: Turkey Creek Survey XS versus LiDAR near 67th Street

At some culvert locations, survey indicated that the culvert inverts were lower than the LiDAR elevations. In these cases, terrain modifications were applied at the upstream and/or downstream of the culverts to ensure the survey inverts were applied in the model as shown in Figure 10.

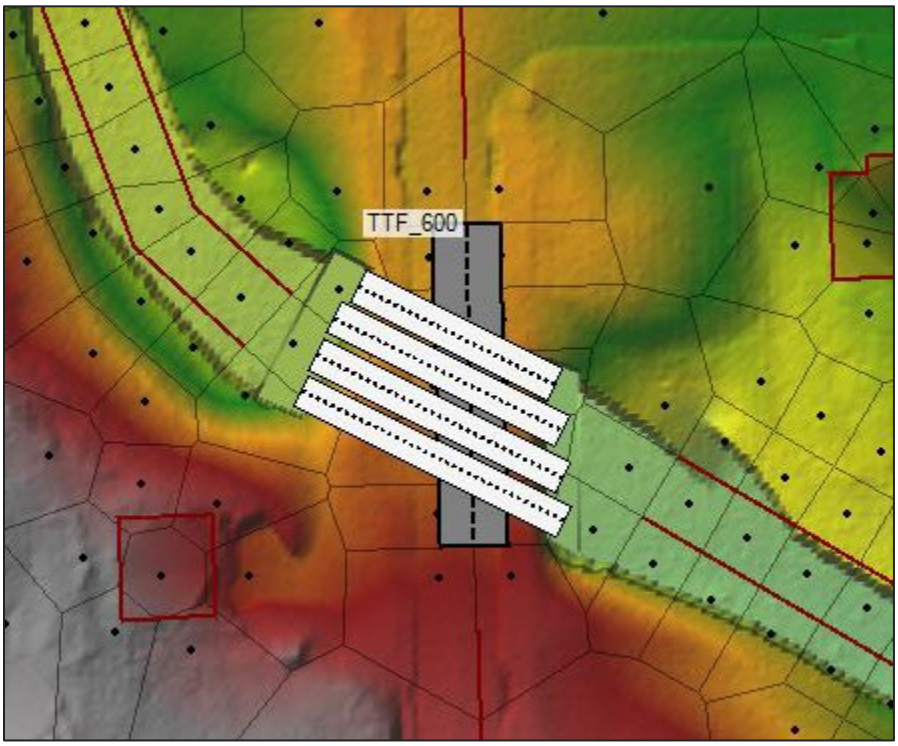

Figure 10: Terrain Modification Example at Culvert

A handful of structures in Brush Creek were irregular culvert shapes. These shapes were not readily available in HEC-RAS, and blocked obstructions were applied to better represent the culvert geometry

within the model. This impacted the following structures in the Brush Creek watershed: BRC_1300, BTU2_200, ROC_1400, RTB_200, RTB_400.

Railings were included on bridges and culverts based on engineering judgement, and they were included if the opening size would likely obstruct the flow should the water reach the railings.

During the model development, if non-surveyed, upstream impoundments or hydraulic connections were discovered based on aerial imagery and Johnson County's stormwater inventory, terrain modifications were applied to ensure flow could pass through the embankment and not cause artificial ponding as shown in Figure 11.

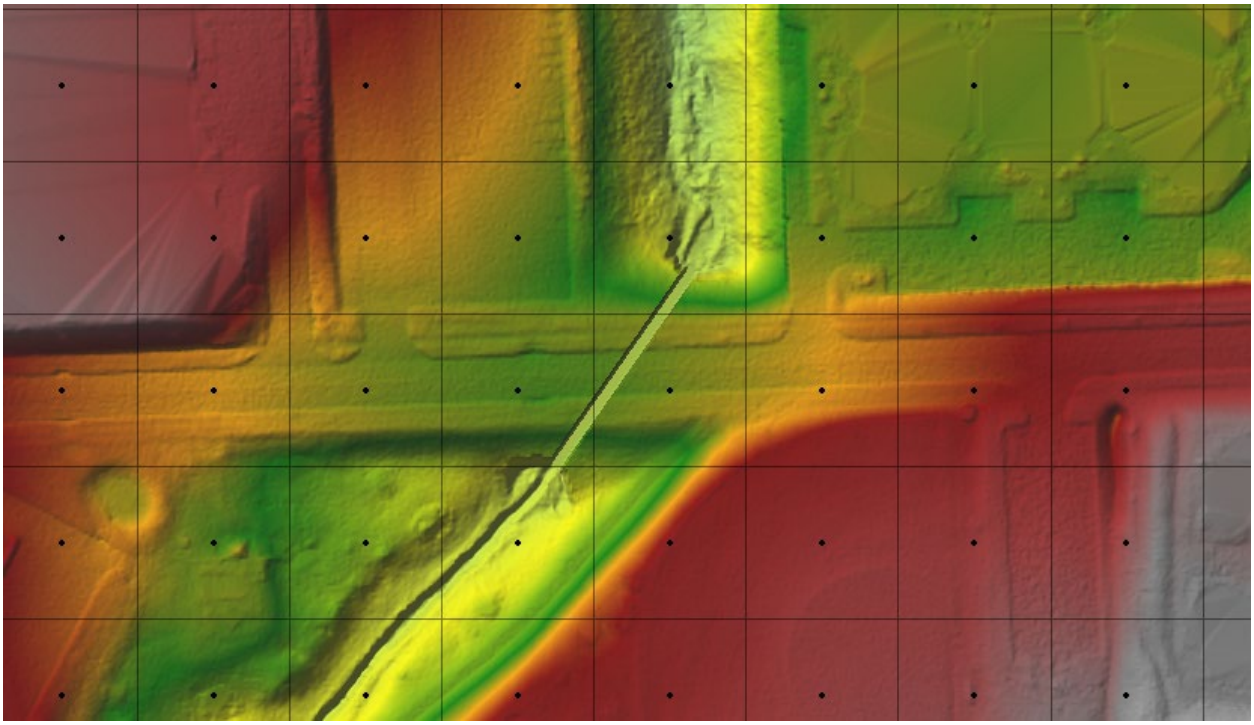

Figure 11: Terrain Modification Example of Upstream Hydraulic Connection

2.1.6 MANNING'S N ROUGHNESS

Manning's n roughness coefficient data was spatially defined for the study area and developed using the most recent aerial imagery provided by Johnson County (AIMS) with additional channel definition. Base roughness values were based on the HEC-RAS 2D User's Manual (Reference 7) and are consistent with the base values applied in the recent 2D analysis of the Indian Creek watershed, also located in Johnson County. These base values serve as the initial condition prior to model calibration. Additional discussion regarding the calibration modifications to the Manning's n roughness coefficients can be found in Section 3.4. Base Manning's n values are shown in Table 5.

The 2D watershed domains applied the spatially varied Manning's n on Faces option in HEC-RAS.

Table 5: Base Manning's n Roughness Coefficients

Description	Base n Value
Trees	0.085
Natural Channel	0.035
Concrete Channel	0.015
Pavement	0.02
Grass	0.03
Buildings	1
Barren Land	0.025
Open Water	0.025

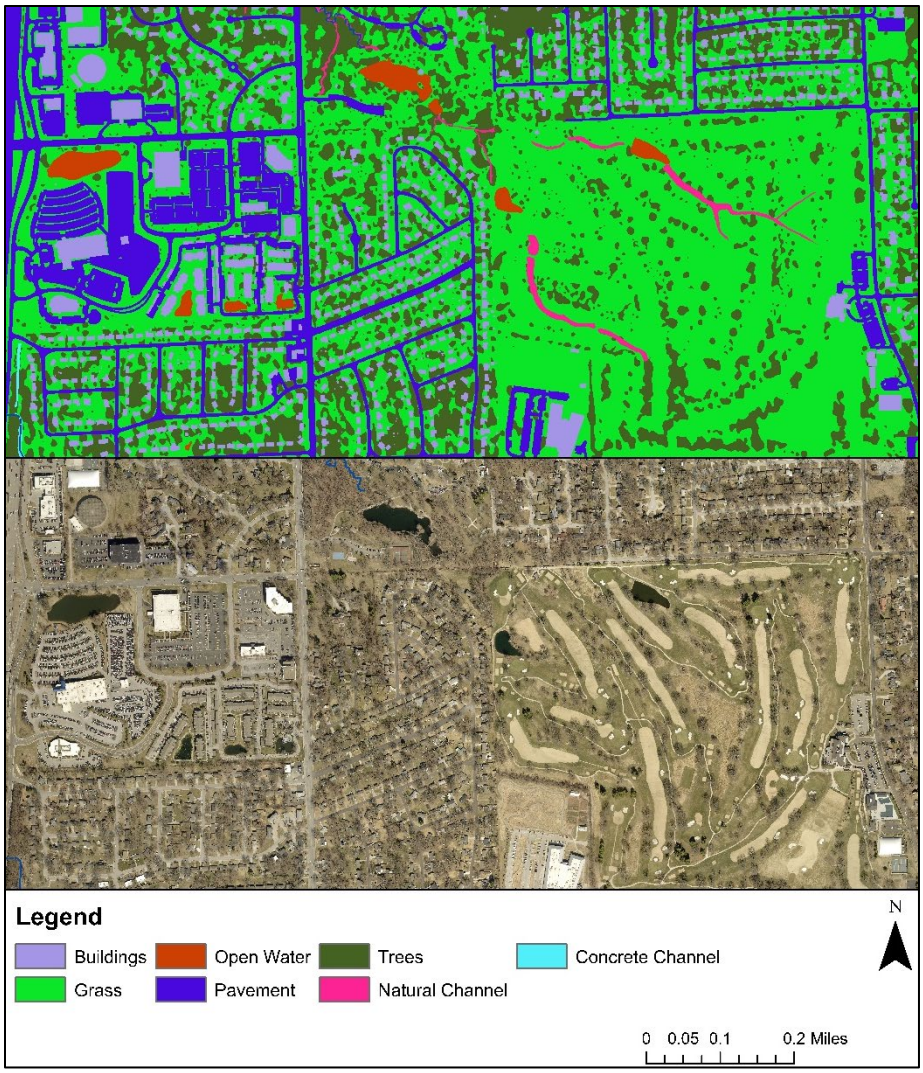

Figure 12: Manning's N Layer based on AIMS Data and Aerial Imagery

2.1.7 MESH REFINEMENT

Based on the cell sensitivity testing completed for the 2D study of the Indian Creek watershed in Johnson County, a base cell size of 100 feet by 100 feet was applied for both the Turkey and Brush Creek watershed models. Additional refinement was applied along stream centerlines and along significant topographic features such as roads and in more populated areas. The cell spacing applied for hydraulic structures (e.g., bridges and culverts), modeled as 2D Area Connections, was 25 x 25 foot and cell faces were aligned perpendicular to direction of flow. The cell spacing applied for channel refinement was 25 x 25 foot. Cell faces were aligned along the streams ensuring cell faces were perpendicular to the direction of flow.

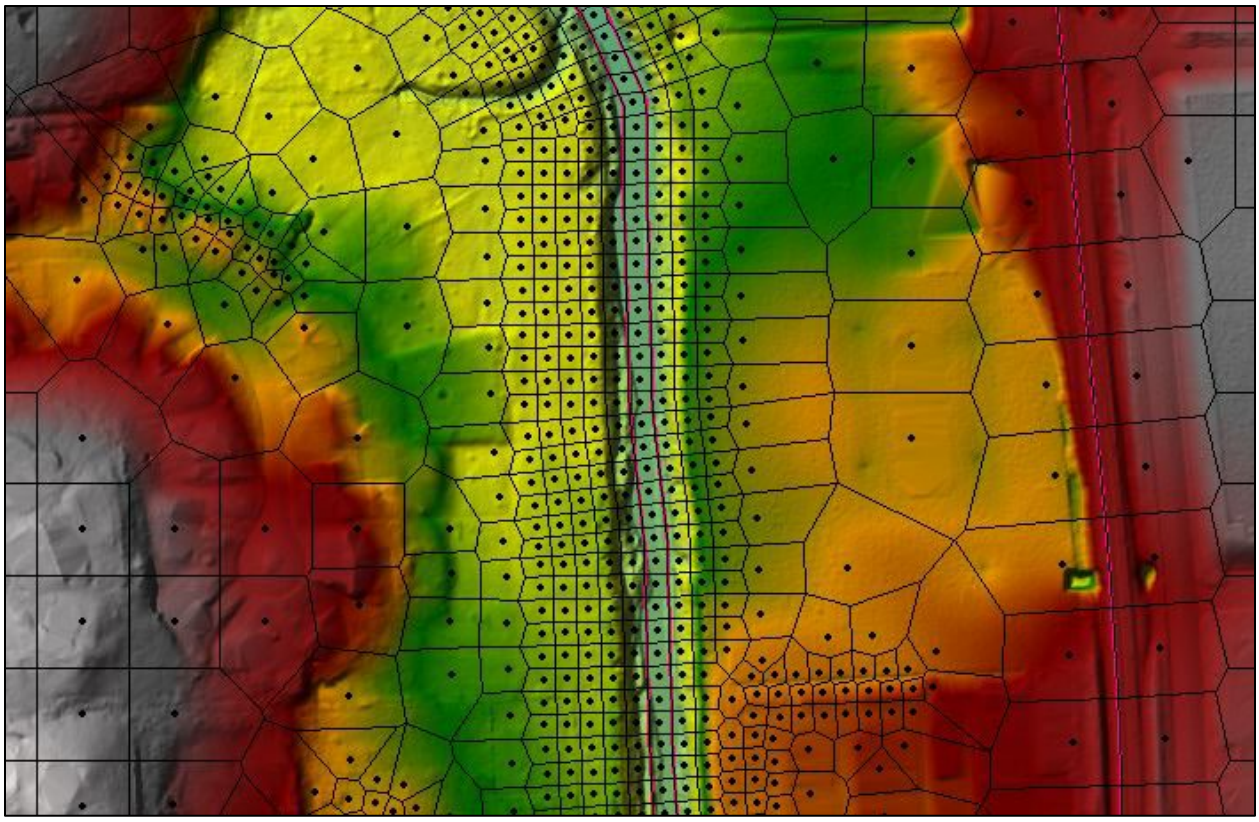

Figure 13: Example of Cell Size Refinement along Stream

Additional refinement was added to structures near the study streams. The AIMS building footprint dataset was leveraged to develop refinement regions within the 2D mesh. A 25 x 25 foot cell spacing was applied to the buildings near the study streams in order to orient cell faces along the building footprints. This mesh alignment applies the higher Manning's n roughness coefficient of the structure to the cell faces so the model recognizes conveyance is minimal at these locations. This application was not applied to all structures in the watershed but those along the floodplain with a larger impact on the conveyance of flood waters.

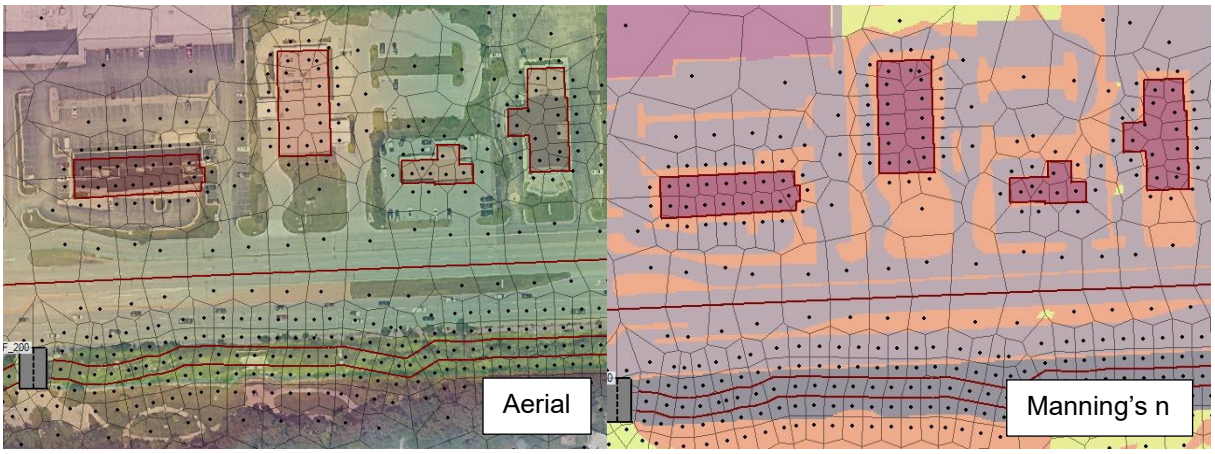

Figure 14: Example of Cell Refinement along Buildings near Streams

2.1.8 LEVEE ANALYSIS

2.1.8.1 Rock Creek Stream Restoration Floodwall

There is one levee located in the National Levee Database (NLD) within the Brush Creek Watershed. NLD System ID 280005000771 (Rock Creek Stream Restoration Floodwall) is a locally constructed, operated, and maintained levee system along Rock Creek in the City of Mission. The area behind the levee system is shown with reduced flood risk due to levee on the effective flood insurance rate map (20091C0024G) from a Letter of Map Revision (LOMR) dated February 8, 2012 (11-07-1190P).

Following FEMA levee guidance, the flood risk along the levee system was analyzed under both 'with levee' and Natural Valley conditions for the synthetic flood frequency events (Reference 10). The 'with levee' geometry includes the floodwall as a 2D connection with the floodwall elevations attributed based on LOMR model floodwall elevations. For the Natural Valley geometry, no 2D connection was included and the terrain elevations were used.

The 'with levee' scenario will dictate the base flood elevations within the channel while the Natural Valley scenario will identify the levee impacted area. As the Turkey and Brush Creek project moves to data development, further levee discussion will occur to determine the mapping path forward for the levee.

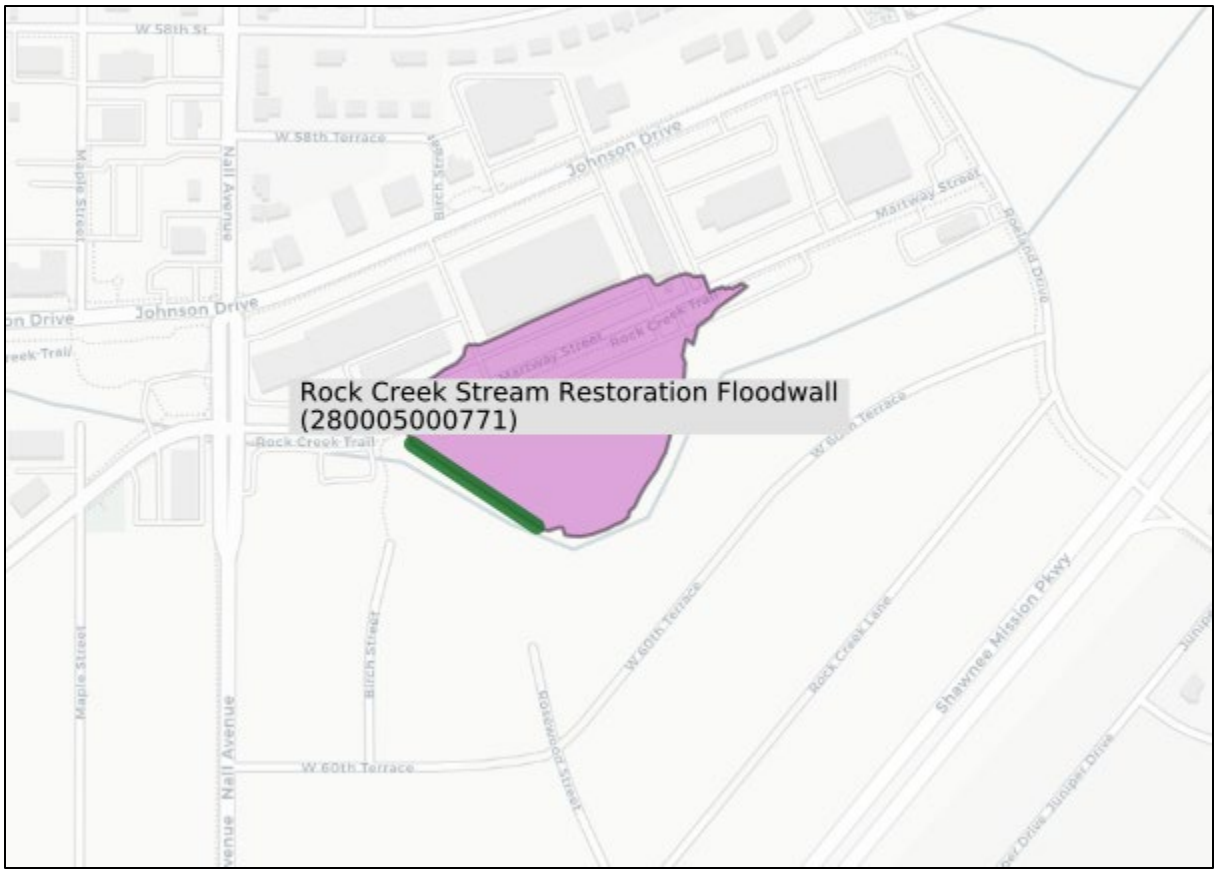

Figure 15: Rock Creek Stream Restoration Floodwall Levee as shown in the NLD

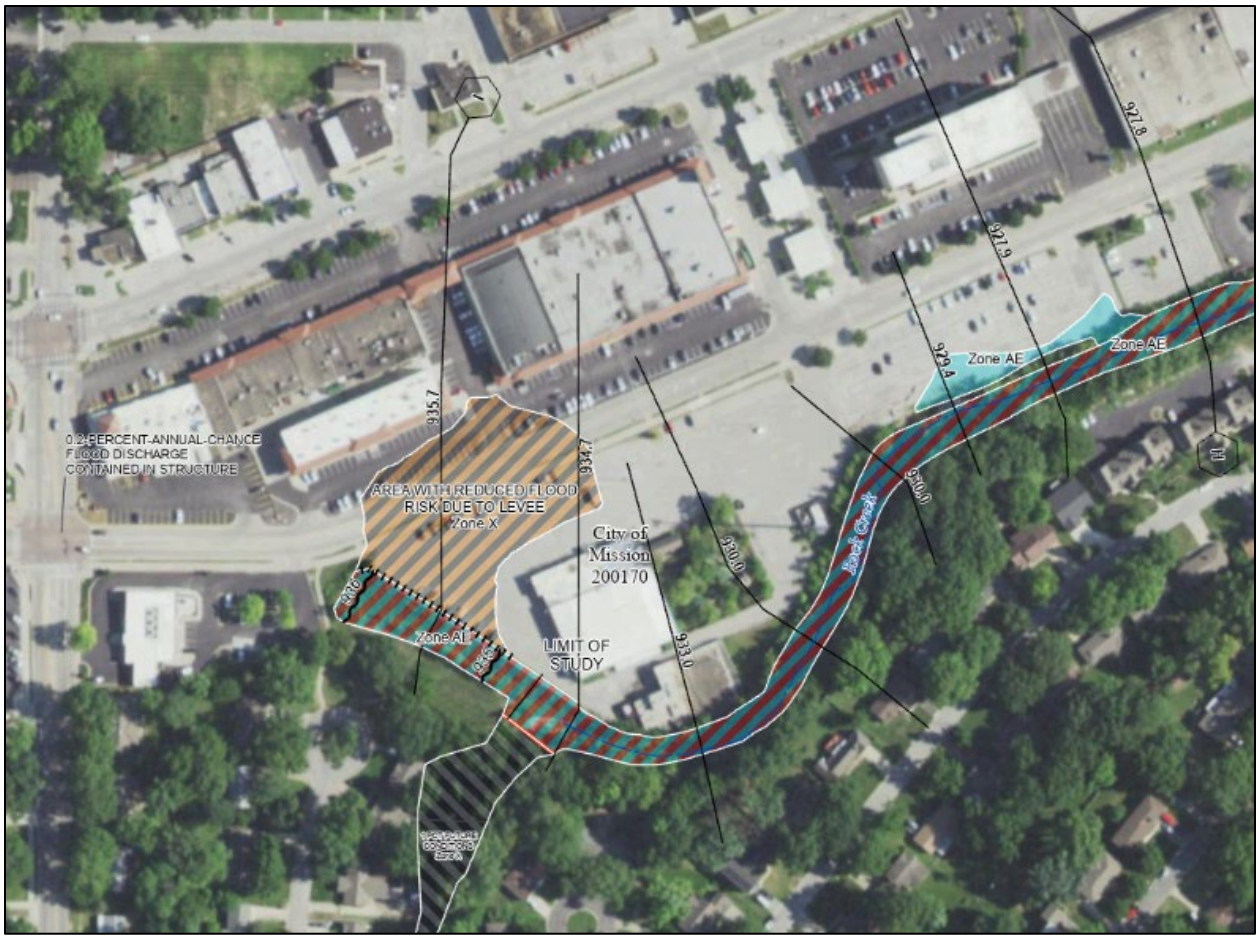

Figure 16: Rock Creek Stream Restoration Floodwall Levee as shown in the National Flood Hazard Layer

2.1.8.2 Brush Creek Floodwall at Roe Avenue

During internal review of the Brush Creek model, it was discovered that a floodwall exists along Brush Creek for approximately 700 feet until Roe Avenue. This floodwall is not shown on the effective FIRM and is not recorded in the NLD. However, it was decided that the floodwall would be included in the levee analysis as it was constructed to protect adjacent properties from flood waters. The same geometry methodology as was used on the Rock Creek flood wall was used for the Brush Creek Floodwall at Roe Avenue. The floodwall was constructed as part of S.M.A.C. Project No. BC-11-054 and design plans from the S.M.A.C. project were used to obtain floodwall elevations and alignments.

The 'with levee' scenario will dictate the base flood elevations within the channel while the Natural Valley scenario will identify the levee impacted area. As the Turkey and Brush Creek project moves to data development, further levee discussion will occur to determine the mapping path forward for the floodwall.

Figure 17: Floodwall along Brush Creek at Roe Ave and W 75th St (Source: Google Earth)

2.1.9 BOUNDARY CONDITIONS

Normal depth boundary conditions were applied to the downstream extent of all modeled terrain. The slope was estimated based on the approximate channel slope at the downstream. For the model domains, each downstream boundary was extended approximately 1-mile downstream of the County boundary to ensure the boundary condition did not have an immediate impact on the water surface elevations at the study extent.

To ensure artificial ponding along the domain boundary was not impacting the hydraulic routing due to the 500-foot HUC12 buffer, an additional normal depth boundary condition was applied to the upstream perimeter of the model to allow non-contributing drainage to leave the domain.

2.1.10 COMPUTATION SETTINGS

The 2D models were run using the Shallow Water Equations, Eulerian-Lagrangian Method. The computational time setting was adjusted based on Courant numbers with a base timestep of 30 seconds. The simulated time step was controlled using the Courant number with specifications outlined in Table 6. The unsteady flow computation settings are outlined in Table 7.

Table 6: Advanced Time Step Controls

Control	Values
Maximum Courant:	1
Minimum Courant:	0.4

Maximum number of doubling base time step:	1 (60 sec)
Maximum number of halving base time step:	5 (0.94 sec)

Table 7: Computation Settings

Setting	Values
Computation Interval:	30 sec
Mapping Output Interval:	6 min
Hydrograph Output Interval:	1 min
Detailed Output Interval:	30 min

3 Calibration

The Turkey Creek and Brush Creek 2D models were calibrated using 2 historic storm events in the watershed. Storm events were chosen based on the magnitude of the event, ideally larger than a 10-percent annual chance event, as well as having occurred recently so that StormWatch data was available to calibrate to in both watersheds. The events selected for calibration were August 22, 2017 and May 28, 2020.

3.1 StormWatch Gages

The City of Overland Park employs a weather and flood warning system called StormWatch which is made up of monitoring stations throughout the metro region. These gages collect rainfall, stream level (stage), and more to provide information about current stream conditions. These gages were used to develop the precipitation input for the calibration events, utilizing the StormWatch precipitation gages and incremental rainfall for the periods of interest. These gages were also used to calibrate the model based on the recorded stages during the historic flood events throughout the watershed.

A total of 27 precipitation gages were used to develop the rainfall for the August 2017 event and a total of 26 precipitation gages were used to develop the May 2020 event. Gage TU08 did not collect precipitation data during the 2020 event. The rainfall data was entered into the HEC-RAS model as Meteorological Data using the gages as meteorological stations to develop the rainfall across the entire domain. The Thiessen Polygon Interpolation method was applied for the historic point gage data to apply the rainfall across the domains. The August 2017 event was simulated from 12:00 AM August 21, 2017 to 12:00 AM August 23, 2017 to capture the whole storm event. The May 2020 event was simulated from 12:00 PM May 27, 2020 to 12:00 PM May 29, 2020.

Stage data is collected at select StormWatch gages. There are 6 StormWatch gages within the Turkey Creek watershed and 4 within the Brush Creek watershed that collected stage measurements during the two selected events that were used calibrate the 2D model parameters. BR04 did not collect stage data for either event, and BR09 did not collect stage data for the 2020 event. BR07 collected data for the 2017 event but was not considered for calibration because the City of Overland Park was not confident in the gage datum as it has been relocated. The City of Overland Park provided gage datum information to ensure the appropriate zero datum was being applied when comparing the observed water surface elevations and the modeled water surface elevations, summarized in Table 8. For concrete channels, the channel bottoms and the zero datum are the same because scour is not taken into consideration. For natural stream channels, the relationship between the checkbar and zero datum is shown in Figure 15.

Table 8: Turkey and Brush Creek Stage Collection StormWatch Gages and Zero Datums

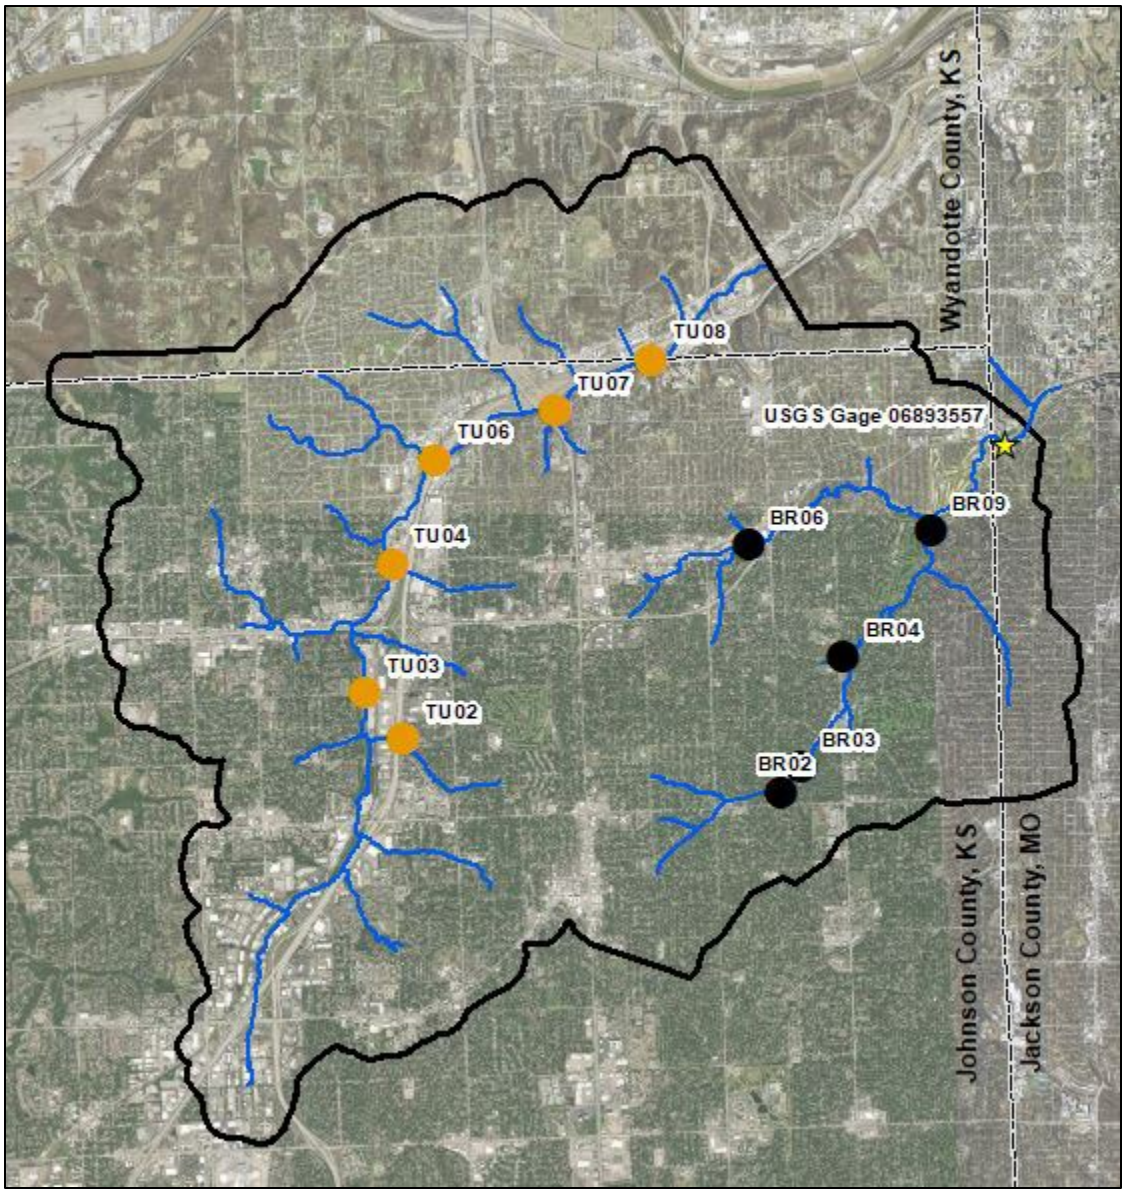

Figure 19: Location of Calibration Gages within the Turkey and Brush Creek Study Area

3.2 USGS Instantaneous Gage Data

There is one USGS gage along Brush Creek, just downstream of the Johnson County, KS and Jackson County, Missouri border, USGS 06893557 Brush Creek at Ward Parkway in Kansas City, Missouri (see Figure 17). The gage collects discharge and height for the periods of record for both historical calibration events. The data is collected on an approximately 15-minute interval. This gage was also used for the historical event calibration with this site having highest priority for calibration as the USGS monitors and maintains the stage-discharge relationship at the gage location.

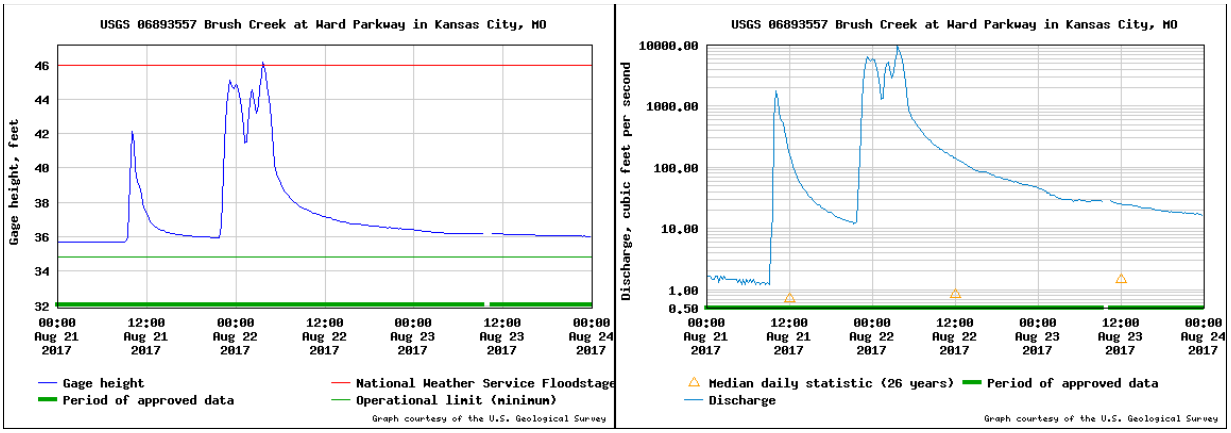

Figure 20: USGS Gage 06893557 Instantaneous Stage and Discharge Data for 2017 Calibration Event

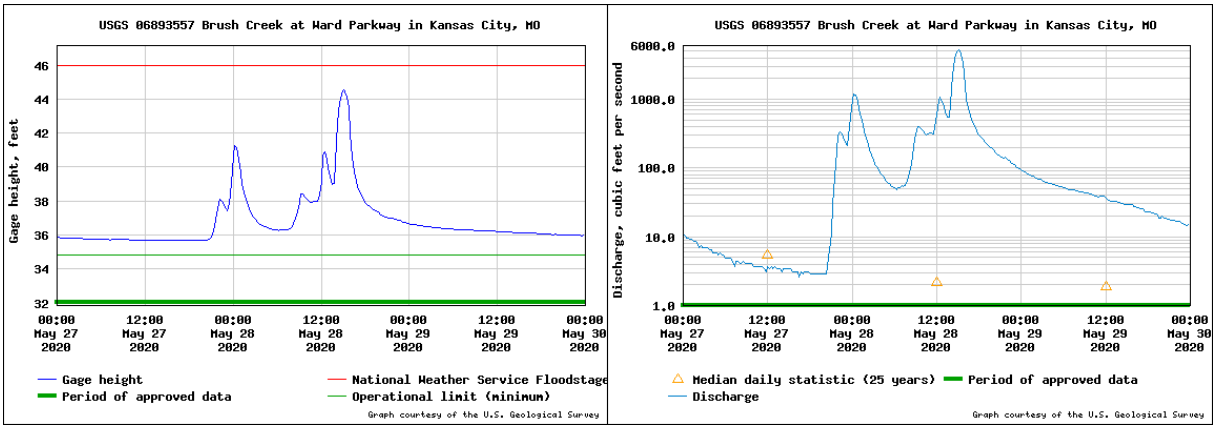

Figure 21: USGS Gage 06893557 Instantaneous Stage and Discharge Data for 2020 Calibration Event

3.3 Calibration Parameters

The desired goal of the calibration exercise was to arrive at a modeled stage height within six inches of the actual gage height recorded during historic storm events and to also closely mirror the timing of the peak gage height.

The parameters that were considered for adjustment during calibration were the abstraction ratio, infiltration Curve Numbers, Manning's n roughness coefficients, a hotstart initial condition, and upland terrain modifications to avoid artificial ponding where storm drain networks were present but not modeled.

Calibration of the parameters between the two watersheds were modified in conjunction with one another so that changes were agreeable between adjacent basins. Further discussion of the calibration parameters is reported in Section 3.4.

3.3.1 AUGUST 2017 EVENT

The StormWatch precipitation gages for the August 2017 event recorded rainfall depths ranging from approximately 4 to 9 inches across the study area (4 to 6 inches within Turkey and Brush Creek).

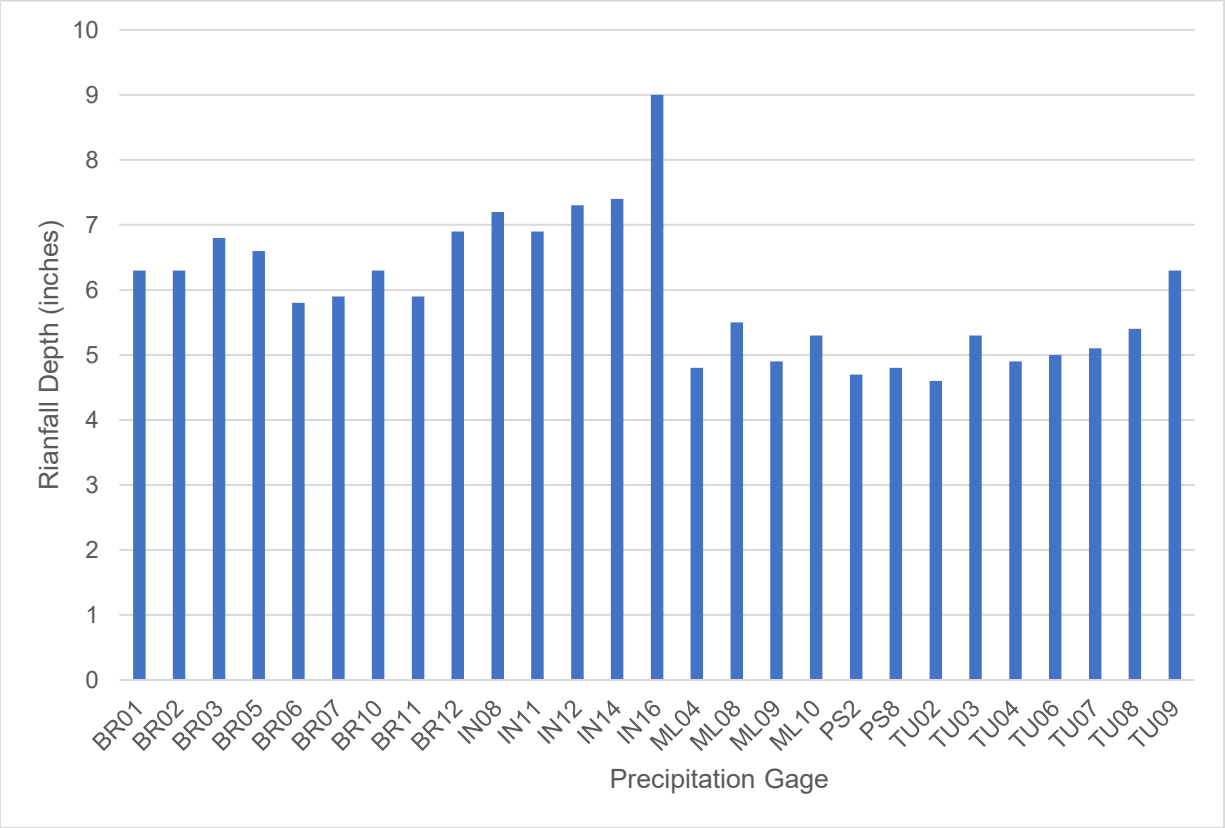

Figure 22: StormWatch Precipitation Totals for August 2017 Event

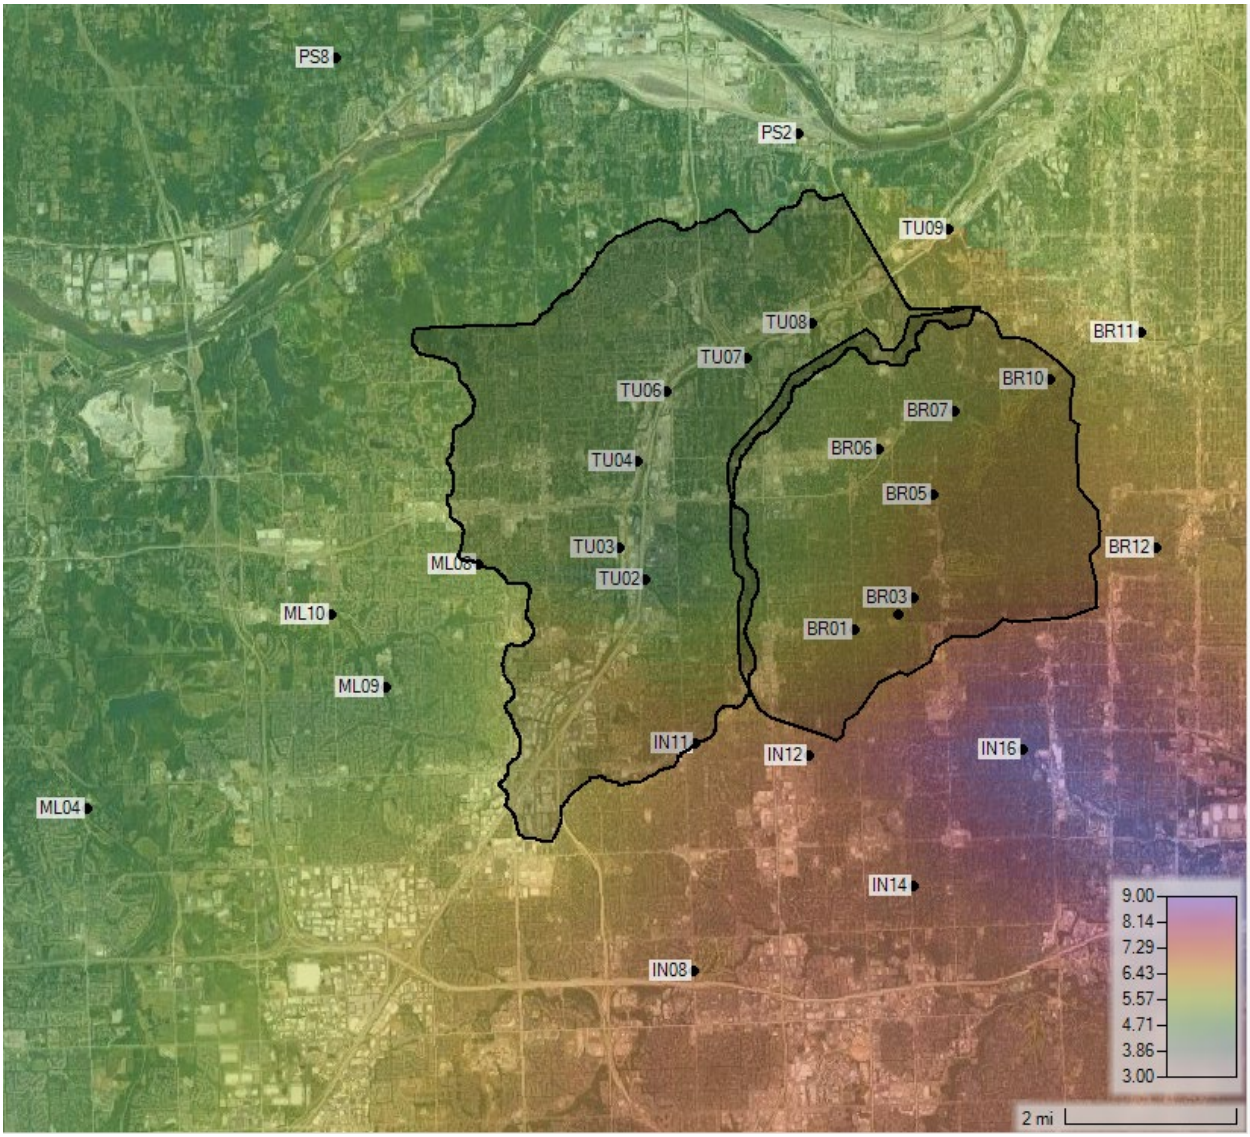

Figure 23: August 2017 Rainfall across Study Area based on StormWatch Gages

Base parameter results of the August 2017 event indicated the overall response was similar to the observed StormWatch stages; however, the magnitude of the peak stage within the Turkey Creek model was mostly larger than the observed StormWatch measurements with the largest difference at gage TU04 at almost 5 feet. Gage TU07 was the only gage within the 0.5-foot tolerance goal at -0.1 feet.

For the Brush Creek model, base parameter results of the August 2017 event also indicated the overall response was similar to the observed StormWatch stages; however, the magnitude of the peak stage within the Brush Creek model was mostly larger than the observed StormWatch measurements with the exception of gage BR06 with a modeled peak 3.1 feet less than the recorded peak. The largest positive difference in modeled stage versus recorded stage occurred at gage BR03 with a modeled stage peak 3 feet greater than the recorded peak. Gage BR02 was the only gage within the 0.5-foot tolerance goal

at 0.2 feet. The modeled stage peak at the USGS gage on brush creek at state line where 0.7 feet greater than the recorded peak.

Base model results compared to observed StormWatch data at each gage can be found in Appendix A.

Table 9: Uncalibrated Model Results Compared to StormWatch Data for August 2017 Event

Gage	Base Model Peak (ft)	Recorded Peak (ft)	Base Difference (ft)
TU02	955.7	**953.2**	2.5
TU03	938.6	**937.5**	1.1

* Gage did not collect data for event

3.3.2 MAY 2020 EVENT

The StormWatch precipitation gages for the May 2020 event recorded rainfall depths ranging from approximately 1 to 5 inches across the study area (2 to 5 inches within Turkey and Brush Creek). Gage TU08 did not record any precipitation for the event.

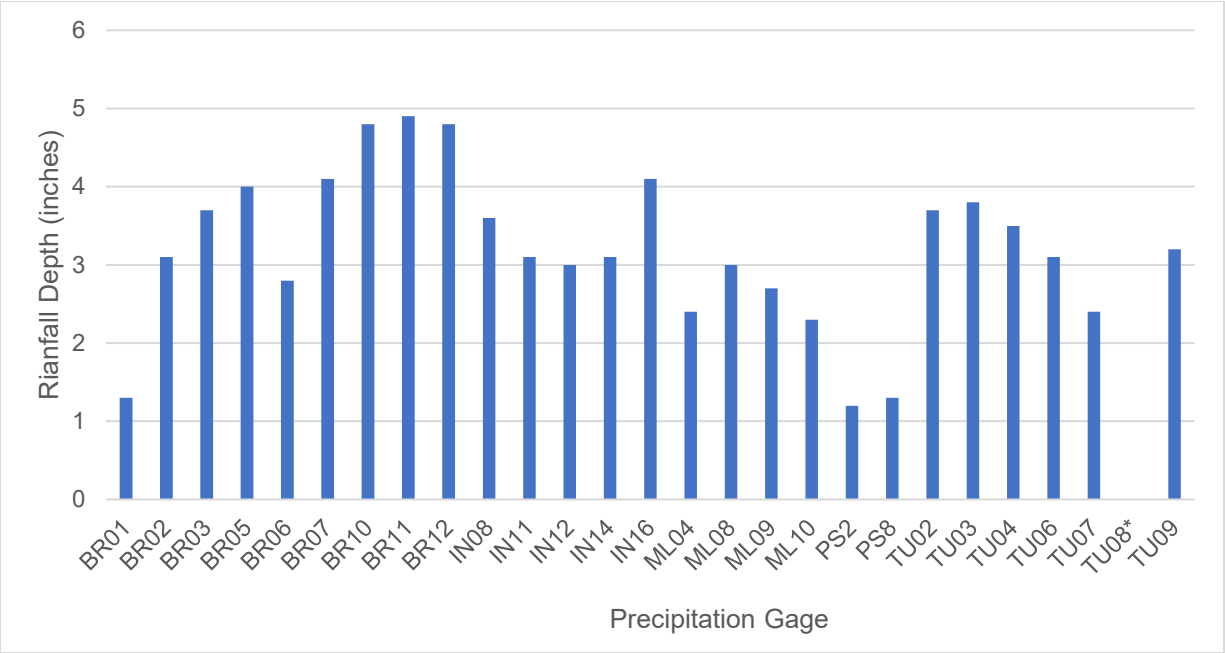

Figure 24: StormWatch Precipitation Gage Rainfall Hyetographs for May 2020 Event

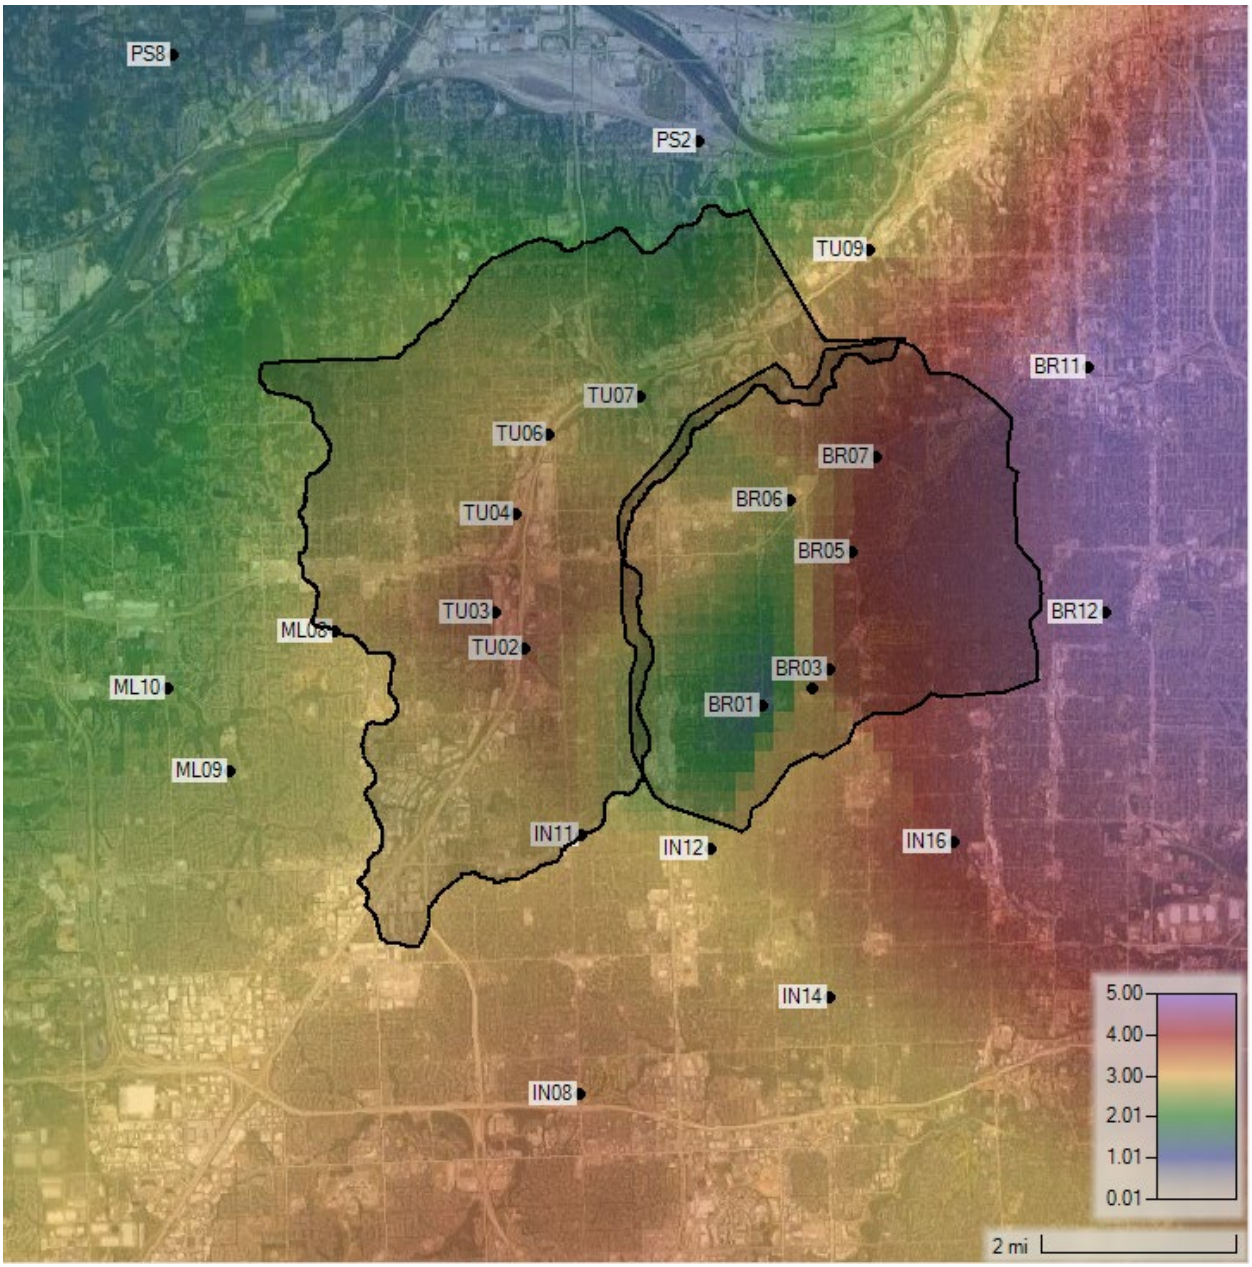

Figure 25: May 2020 Rainfall across Study Area based on StormWatch Gages

Similar to the 2017 event, initial model results showed the stage hydrograph shape closely followed the observed StormWatch stages; however, there were still discrepancies in Turkey Creek with the peak stages as half of the gages simulated higher than observed stages and half the gages simulated lower than observed stages. Again, gage TU04 showed the largest stage discrepancy of all the StormWatch gages in Turkey Creek, reporting a stage 2.7 feet higher than the observed stage.

The initial model results for Brush Creek also showed that the stage hydrograph shape closely followed the observed StormWatch stages; however, two of the three stormwatch gages on Brush Creek with recorded stages for the 2020 event recorded peak stages more than 0.5 feet higher than the base model results. Similarly, the USGS gage recorded a peak stage 1 foot higher than the base model results.

Base model results compared to observed StormWatch data at each gage can be found in Appendix B.

Table 10: Uncalibrated Model Results Compared to StormWatch Data for May 2020 Event

Gage	Base Model Peak (ft)	Recorded Peak (ft)	Base Difference (ft)

3.4 Observed Event Calibration Data

3.4.1 PARAMETER SENSITIVITY

The modeling parameters considered for calibration were the curve number, abstraction ratio, and Manning's n roughness coefficients. These parameters have the least amount of certainty and impact the volume, peak, and timing of the flood response. These parameters are estimated from physical data about streams and watersheds, but the values are not exact. The watersheds were evaluated using a range for CN, abstraction ratio, and Manning's n values for the study area to evaluate the sensitivity to the model results. A high and low run were simulated for CN and Manning's n values. The high and low values for the Manning's n roughness coefficients were determined based on the ranges reported in the HEC-RAS 2D User's Manual. Additionally, the manual notes that n values for shallow, overland flow are generally much higher due to the relative roughness compared to the flow depth. While HEC-RAS has not published any Manning's n values for shallow, overland flow, TR-55 does have published values for sheetflow which were considered for an uplands calibration region. The uplands area was determined

based on a buffer from the channel locations identified in the land classification layer. Smaller, upland channels applied an approximate buffer of 100 feet and increases as the stream and corresponding floodplain areas are larger. The ‘Uplands Area’ for Turkey Creek and Brush Creek can be seen in Figure 26. Again, a high and low scenario were run.

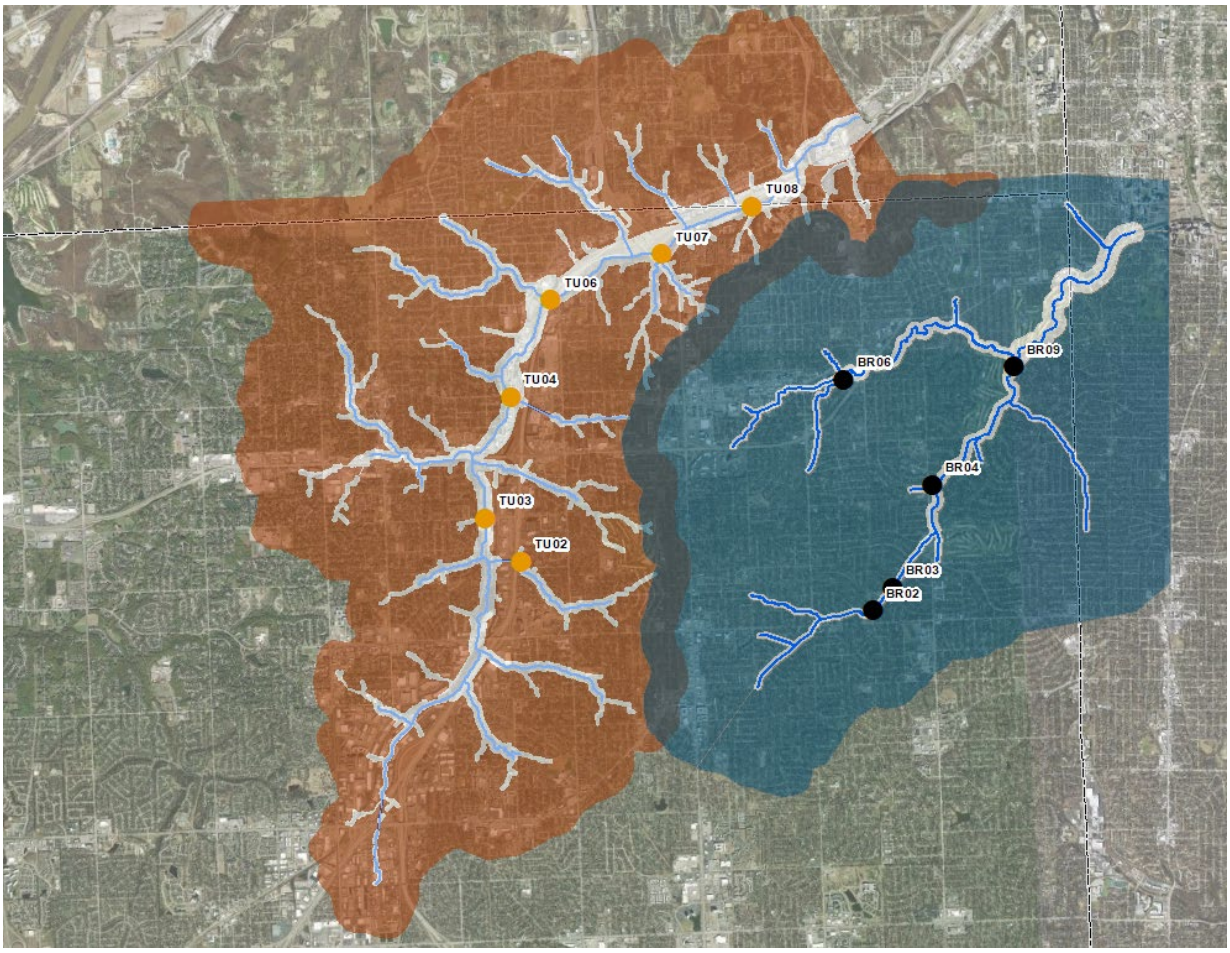

Figure 26: Uplands Area Refinement in Turkey and Brush Creek 2D Models

High and low CN simulations were run by increasing and reducing the base CN for pervious land classifications by a value of 3 to assess the sensitivity of the model response. No changes were made to impervious surface CN; these values were left at 98 and 100. The abstraction ratio was run under a base condition of 0.2; the sensitivity tests ran scenarios where the value was changed to 0.1 and 0.05.

Finally, a hotstart initial condition was run to assess the sensitivity of the results from the dry assumption. For this scenario, the end of simulation of the 10-percent annual chance synthetic event was used as the initial conditions for the simulation. The sensitivity runs are summarized in Table 11. More details on the specific modeling parameters used in the sensitivity testing and results at each comparison location can be found in Appendix A.

Table 11: Parameter Sensitivity Run Summary

Scenario Name	Parameter Updates
High Mann	Update base Manning's n values to high end of recommended values in HEC-RAS Manual (No modification to base CN)
Low Mann	Update base Manning's n values to low end of recommended values in HEC-RAS Manual (No modification to base CN)
High Mann - Upland Refine	Upland calibration region added with high end of TR-55 sheetflow values (Base Manning's n in floodplain, no modification to base CN)
Low Mann - Upland Refine	Upland calibration region added with low end of TR-55 sheetflow values (Base Manning's n in floodplain, no modification to base CN)
Low CN	Base CN reduced values by 3 (No changes to Impervious CN 98 or 100, no modification to base Manning's n)
High CN	Base CN increased values by 3 (No changes to Impervious CN 98 or 100, no modification to base Manning's n)
Ia = 0.1	Abstraction Ratio set to 0.1 (Base CN, Base Manning's n)
Ia = 0.05	Abstraction Ratio set to 0.05 (Base CN, Base Manning's n)
Hotstart	Initial conditions set to the end of simulation for the 10-percent rainfall event

Turkey and Brush Creek showed similar sensitivity to the modeling parameters investigated. Brush Creek was more sensitive to the hotstart, showing increases in stage at all gage check locations in the magnitude of 1-2 feet from the base condition while the Turkey Creek model only showed impacts of 0.5 feet or less at the comparison locations. This is likely due to more runoff storage existing in the Brush Creek Watershed.

The most impactful parameter to lowering the stages were the addition of the upland Manning's refinement regions, with the higher Manning's upland refinement resulting in the lowest stages in both basins.

Increasing and decreasing the CN showed minor impacts to the stage in both basins, resulting in an increase or decrease of less than 0.5 ft, on average. The impact of reducing the abstraction ratio similar effect as increasing the CN by 3, with an increase in stage of approximately 0.5 ft. The Brush Creek and Turkey Creek models showed different responses to changing the abstraction ratio from 0.1 to 0.05. In the Turkey Creek model, the further reduction to 0.05 resulted in slightly higher stages in the order of 0.25 ft.

HEC-RAS peak stage and flow rates were expected to be inversely related to the initial abstraction ratio as it impacts the total volume of runoff in the watershed. However, results in Brush Creek showed that as the initial abstraction ratio was reduced from 0.2 to 0.1 and finally 0.05 the peak stage and flow rate at stream gages on the downstream end of the watershed were highest with the 0.1 value followed closely by 0.05 and then the base 0.2. This can be explained by the effect of how HEC-RAS handles the initial abstraction ratio on hydrograph timing. As the initial abstraction ratio is increased the time to the start of hydrograph runoff is also increased. As shown in Figure 27. This change in the time of runoff initiation changes the hydrograph's shape as it attenuates downstream and causes artificial

alignment of flow peaks. Based on the sensitivity testing, the watersheds are not sensitive to abstraction ratios less than 0.1.

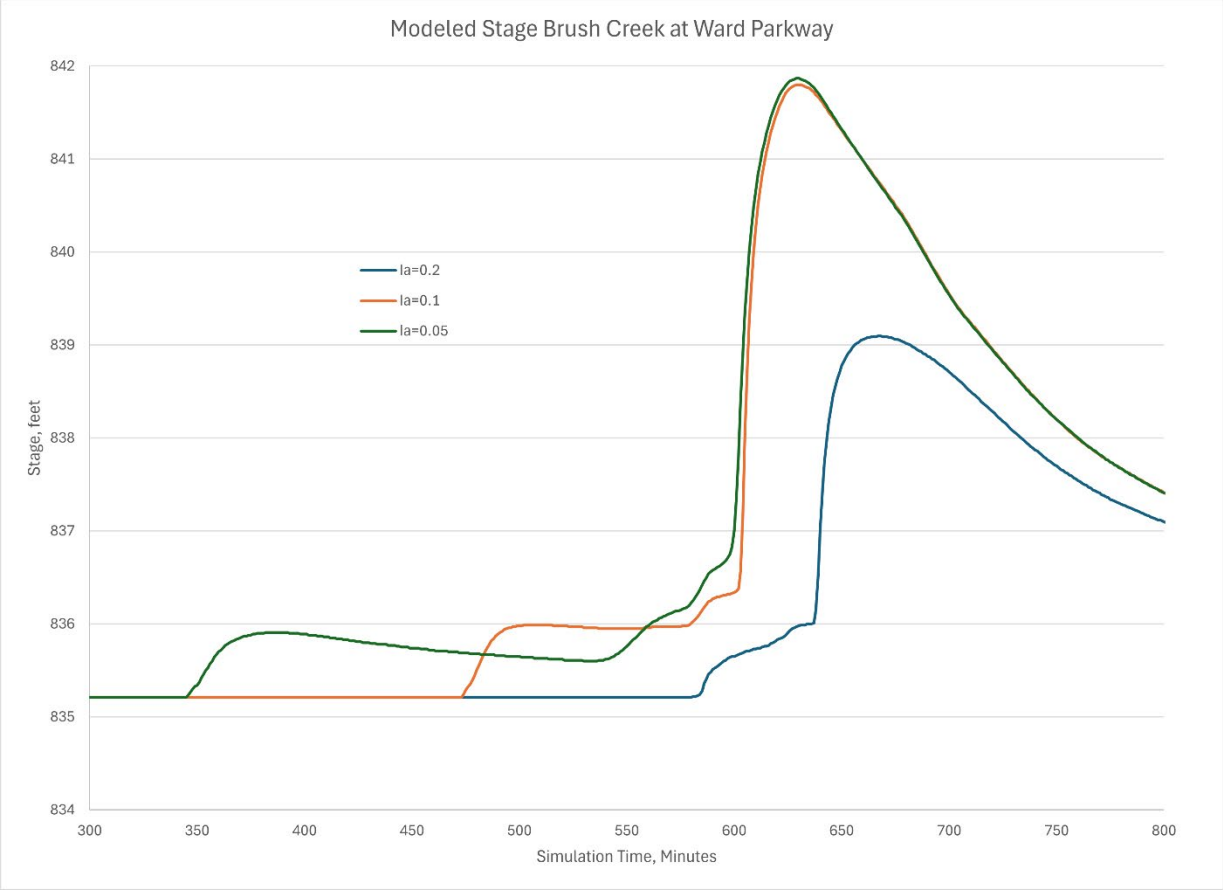

Figure 27: Abstraction Ratio Sensitivity in Brush Creek Model

3.4.2 FINAL MODEL PARAMETERS

Initial discussions with the City of Overland Park regarding the previous datums of the StormWatch gages indicated there could be some uncertainty associated with historical readings; however, there is no indication specific gages within the Turkey or Brush Creek watersheds should be considered unreliable for the historical events. Therefore, equal weight was given to all StormWatch gage locations when considering the basin calibration. Base results and test runs revealed some gage locations with higher stages than observed and others with lower stages than observed indicating that uniform modifications throughout the watershed would not result in reaching a 0.5 foot calibration tolerance at each gage. Accordingly, the model parameter calibration focused on minimizing the absolute difference in stage at all of the StormWatch gage locations.

Based on the initial parameter sensitivity testing and the majority of the gage locations for both events producing higher stages than the observed data, an upland Manning's n refinement region was added. Additionally, the abstraction ratio was reduced to represent the runoff more accurately in the fully developed basins.

Multiple iterations of the August 2017 and May 2020 event were simulated with varying degrees of change to the Manning's n roughness coefficients to evaluate the impact to the resulting stage at each of the StormWatch calibration locations.

In the Brush Creek Watershed the calibrated parameter values from the Turkey Creek Watershed model where used. A Manning's n refinement region was added within the stream channel at the downstream reaches of Brush Creek and Rock Creek. Channel roughness along Brush Creek and Rock Creek ranged from 0.029 to 0.035.

For the Turkey Creek watershed, for both calibration events, the model results at gages TU04 and TU06 were consistently much higher than the observed stages. Just downstream of TU06, gages TU07 and TU08 exhibited modeled stages much closer to the StormWatch stages. In an effort to avoid decreasing stages everywhere in the watershed to get gages TU04 and TU06 more in-line with the observed data, Manning's n calibration regions were added along Turkey Creek to adjust the channel roughness values at different locations. Channel roughness along Turkey Creek ranged from 0.025 to 0.035 with the lower n values along the stretch of Turkey Creek along TU04 and TU06.

The final calibrated Manning's n roughness coefficients for the Turkey and Brush Creek watersheds are summarized in Table 12. For the uplands area, it was assumed that the roughness for trees was controlled by grass understory cover because the watershed is highly developed and no true forest areas are present.

Table 12: Calibrated Manning's n Values based on Historic Events

Description	Base n Value	Calibrated Values	
		Floodplain n Value	Upland n Value
Trees	0.085	0.060	0.140
Natural Channel	0.035	0.035	0.035
Concrete Channel	0.015	0.015	0.015
Pavement	0.020	0.015	0.020
Grass	0.030	0.030	0.140
Buildings	1	1	1
Barren Land	0.025	0.025	0.045
Open Water	0.025	0.025	0.030

There were no modifications made to the base curve numbers (Table 4). The final abstraction ratio for both basins was set to 0.1.

Based on the sensitivity testing, there was minimal impact to peak stages in the Turkey Creek watershed when applying the hotstart. While the Brush Creek model showed more impact to a hotstart, the observed data suggested that the model was overestimating stage under this initial condition. This could be due to runoff storage no longer being available. A hotstart was not applied to either watershed model for the final calibration.

The final calibrated model results for the August 2017 and May 2020 historic events are summarized in Table 13. Stage hydrograph plots for each gage location can be found in Appendix B and C.

* Gage did not collect data for event

For the Turkey Creek model, it was not possible to achieve a 0.5 foot calibration at each gage location due to the differences observed at the StormWatch gages within the basins. Compared to the observed, TU02, TU04, and TU06 reported model stages higher than observed while TU03, TU07, and TU08 reported model stages at or lower than observed. Therefore, universal changes to the model with inversely impact these gages. The applied model adjustments reduced the overall absolute difference at the gage locations while not being overly conservative to lower the stages at TU04 and TU06 that would likely result in artificially low stages at TU03, TU07, and TU08. Figure 27 below shows the initial (base) differences between the 2D model and observed StormWatch stages and the final calibrated differences.

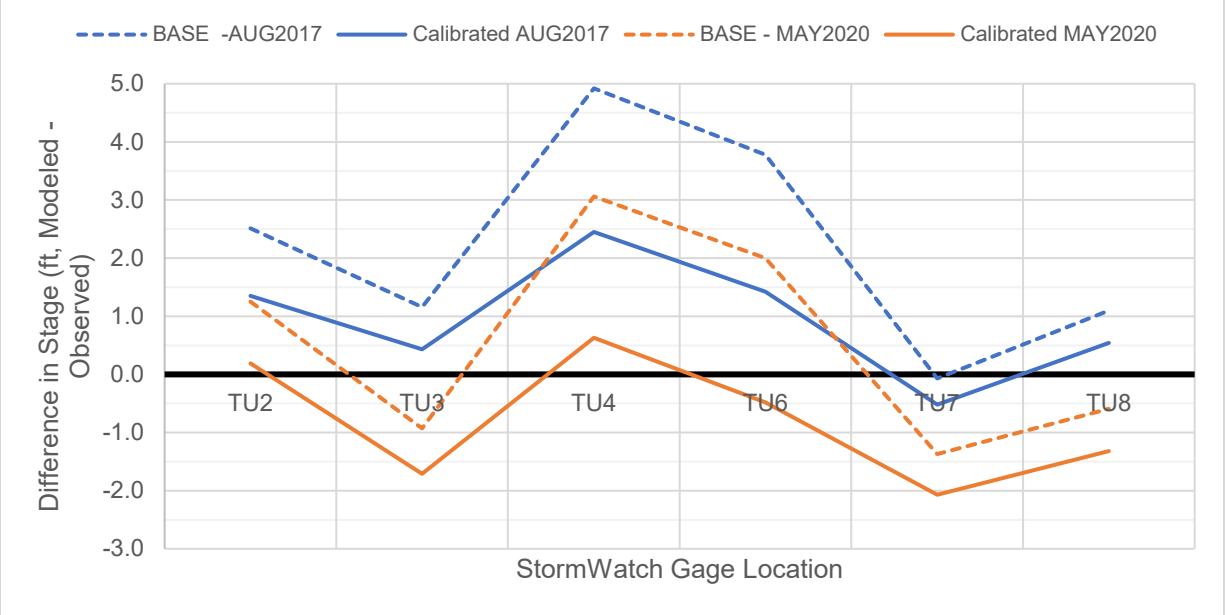

Figure 28: Differences in Turkey Creek Modeled versus Observed Stages from Base and Calibrated Events

Simularly for the Brush Creek model, it was not possible to achieve a 0.5 foot calibration at each gage location due to the differences observed at the StormWatch gages within the basins. Compared to the observed, BR03, and BR04 reported model stages higher than observed while BR06 reported model stages at or lower than observed. Therefore, universal changes to the model will inversely impact these

gages. The applied model adjustments reduced the overall absolute difference at the gage locations while not being overly conservative to lower the stages at BR06. Figure 27 below shows the initial (base) differences between the 2D model and observed StormWatch stages and the final calibrated differences.

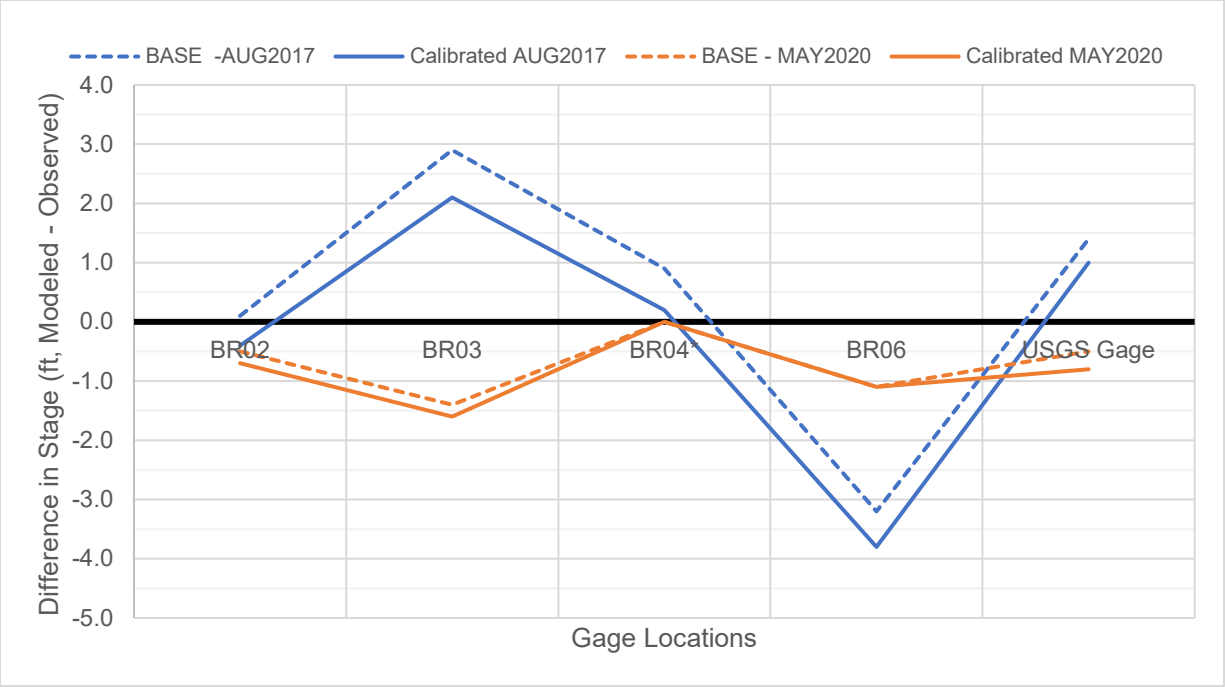

Figure 29: Differences in Brush Creek Modeled versus Observed Stages from Base and Calibrated Events (BR04 no observed data for 2020)

3.4.3 MODEL LIMITATIONS

Calibration of the watershed models to the StormWatch gages could not meet the 0.5 foot criteria initially proposed. There are a variety of factors that potentially impact the watershed response. While the StormWatch point precipitation data is collected at a high-resolution interval, it is only at point specific locations. The interpolation across the watershed likely results in some over and under estimation of rainfall for the historic events.

Additionally, the StormWatch calibration locations record the water stage which is highly dependent on the local channel hydraulics. The 2D model relies on the LiDAR and channel survey to route the flood water and determine water surface elevations. Turkey, Brush, and Rock Creeks can be turbulent channels with pools and riffles. Discrepancies between the LiDAR cross-sectional area and the true channel cross-sectional area at the StormWatch gage locations may also contribute to differences between the modeled stages and the observed stages.

Finally, HEC-RAS currently does not have the capability to incorporate enclosed storm drain networks. Both the Turkey and Brush Creek watersheds are highly urbanized with extensive storm drain

networks. These systems were not modeled in the 2D domains and therefore, the watershed response timing is impacted as seen in the slight delay in 2D hydrograph response at the StormWatch gages compared to the observed data. The impact of these systems would be most impactful on smaller events where these systems can handle the runoff volume. The 2D models have incorporated terrain modifications to simulate some conveyance through these systems but is not intended to model the enclosed systems. While the storm drain systems are not included, the model can still provide valuable information in the upland areas where these systems exist. Overland flows are routed based on the terrain and highlight potential consequence of failure and inundation extents.

3.5 July 2017 Validation

An additional high flow event was evaluated post calibration to validate the model response to large historic events. The July 2017 StormWatch rainfall was simulated in the model and results were compared to the observed StormWatch stages at the gage locations. Rainfall for this event was ranged from approximately 4 to 6 inches across the watershed, as shown in Figure 29.

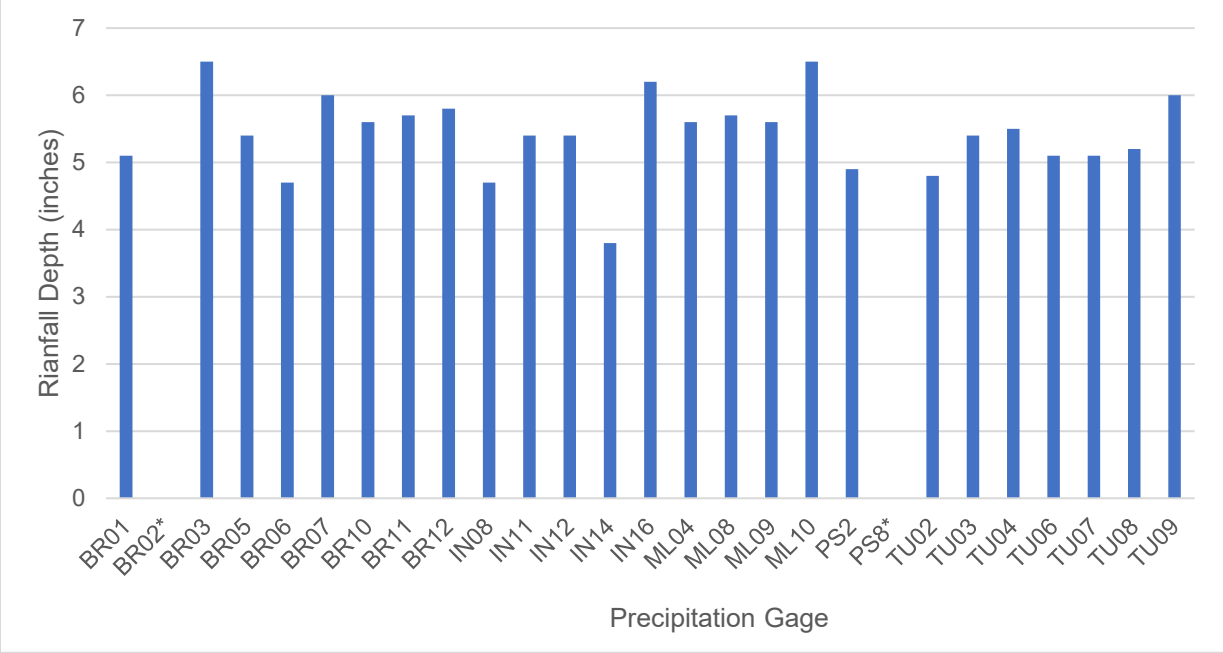

Figure 30: StormWatch Precipitation Totals for July 2017 Event (*gage did not collect data)

Similar to the calibration events, in the Turkey Creek watershed, TU04 and TU06 reported stages higher than the observed, while TU02, TU03, and TU07 reported stages lower and TU08 was in agreement with observed. The model produced similar results for this high flow event as observed during calibration events. While the validation event was still not within the desired 0.5-foot tolerance, the average absolute difference for all gages was 1.2 feet. Figure 30 below shows the differences in stage at each gage location for the calibration and validation events in Turkey Creek.

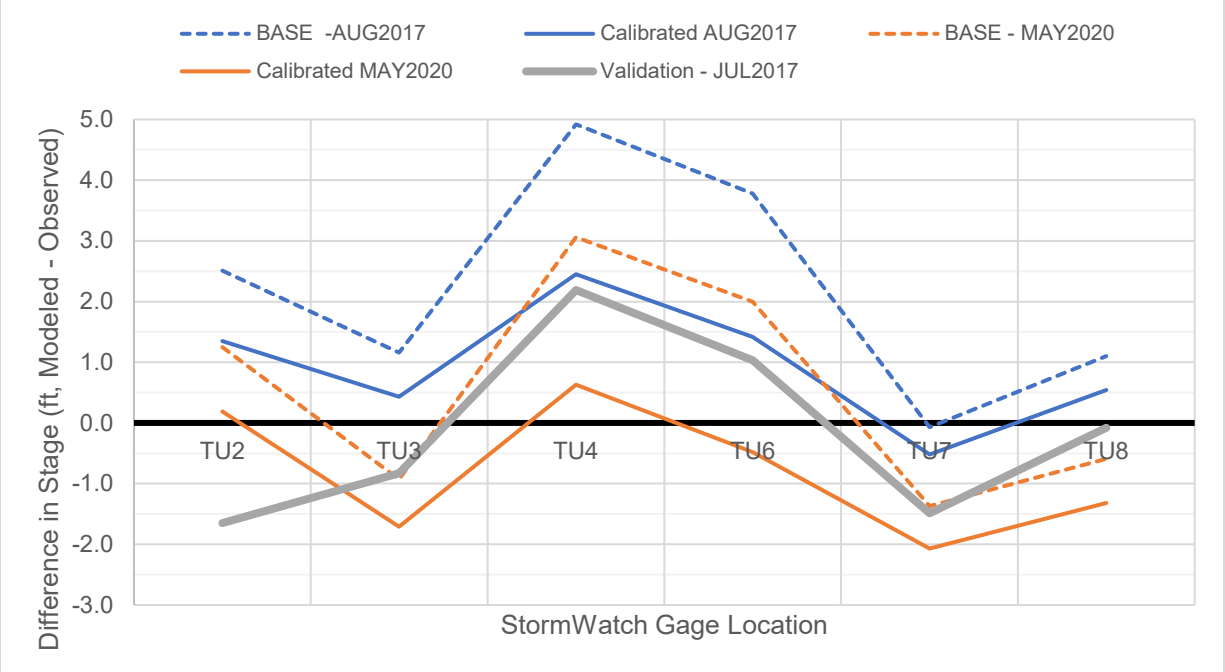

Figure 31: Differences in Turkey Creek Modeled versus Observed Stages with July 2017 Validation Event

While the results of the May 2020 event in Brush Creek showed model estimates lower than the observed stages, the larger flood events did not demonstrate this underestimation. The July 2017 event matched the observed data almost exactly for the BR02 and BR06 gages and were higher than observed for the 3 additional gages.

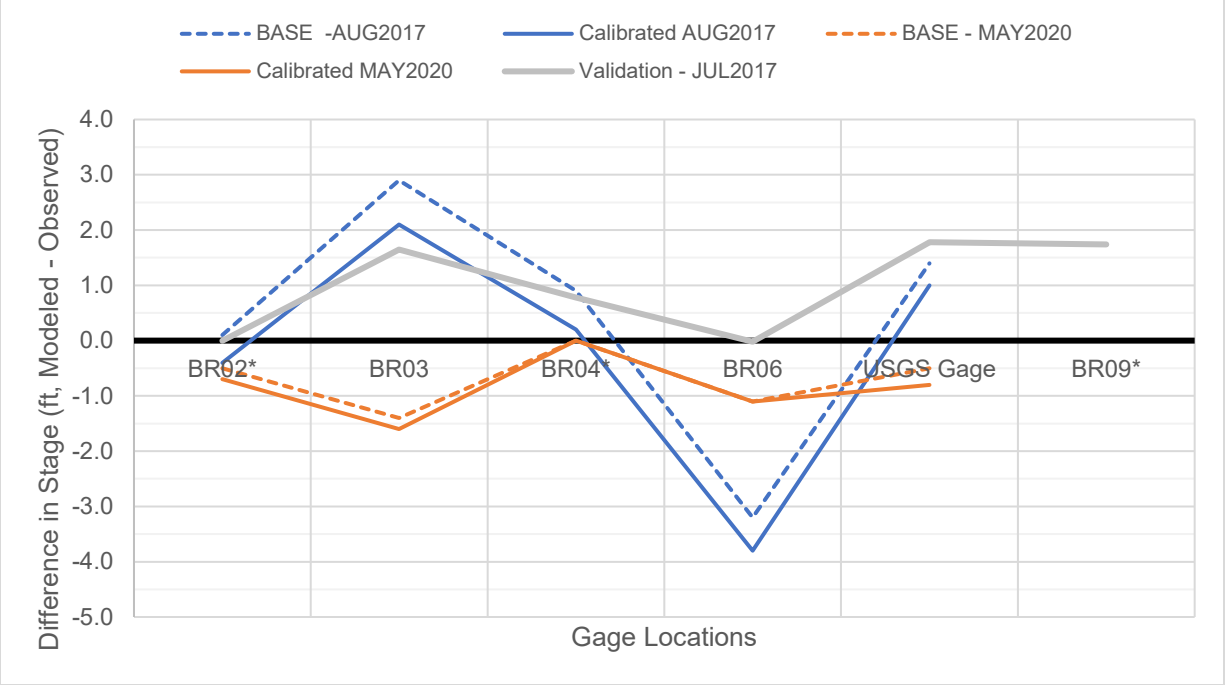

Figure 32: Differences in Brush Creek Modeled versus Observed Stages with July 2017 Validation Event (BR02 no data for July 2017, BR04 no data for May 2020, BR09 no data for August 2017 or May 2020)

Stage hydrographs for the July 2017 event at the StormWatch gage and USGS gage locations can be found in Appendix D.

4 Synthetic Event Simulation

The 50-, 10-, 4-, 2-, 1-, 1plus-, and 0.2-percent annual chance exceedance events were also applied to the calibrated Turkey and Brush Creek models. Single precipitation depths based on NOAA Atlas 14, using a 12-hr, 3-hr peak, distribution were simulations as discussed in Section 2.1.1.

4.1 USGS Gage Frequency Analysis & Rating Curve

There is one USGS stream gage located within the Turkey Creek watershed in the City of Merriam along Turkey Creek in Johnson County, Kansas. There is one USGS stream gage located just downstream of the Johnson County boundary along Brush Creek in Jackson County, Missouri. Only the USGS gage along Brush Creek collects instantaneous streamflow and stage data.

Both of these gages have 20+ years of peakflow data and these gages were used for the validation of flows in the Turkey and Brush Creek models. The USACE software HEC-SSP was used to develop estimates for the 1-percent-annual-chance event using 17C analysis. The results of that analysis for the

USGS gages in the Turkey and Brush Creek watersheds are summarized in Table 15. HEC-SSP output can be found in Appendix E.

Table 15: USGS Gage Analysis for 2D Watershed Calibration

USGS Station ID	Drainage Area (sq.mi)	Flooding Source	Years of Record	1% Annual Chance Discharge (cfs, 17C)
06892800	6.76	Turkey Creek	22 (1974-1986*, 2006-2016)	9,678
06893557	12.2	Brush Creek	24 (1999-2022*)	12,890

*gage records missing year 1985 for Turkey Creek and 2016 for Brush Creek

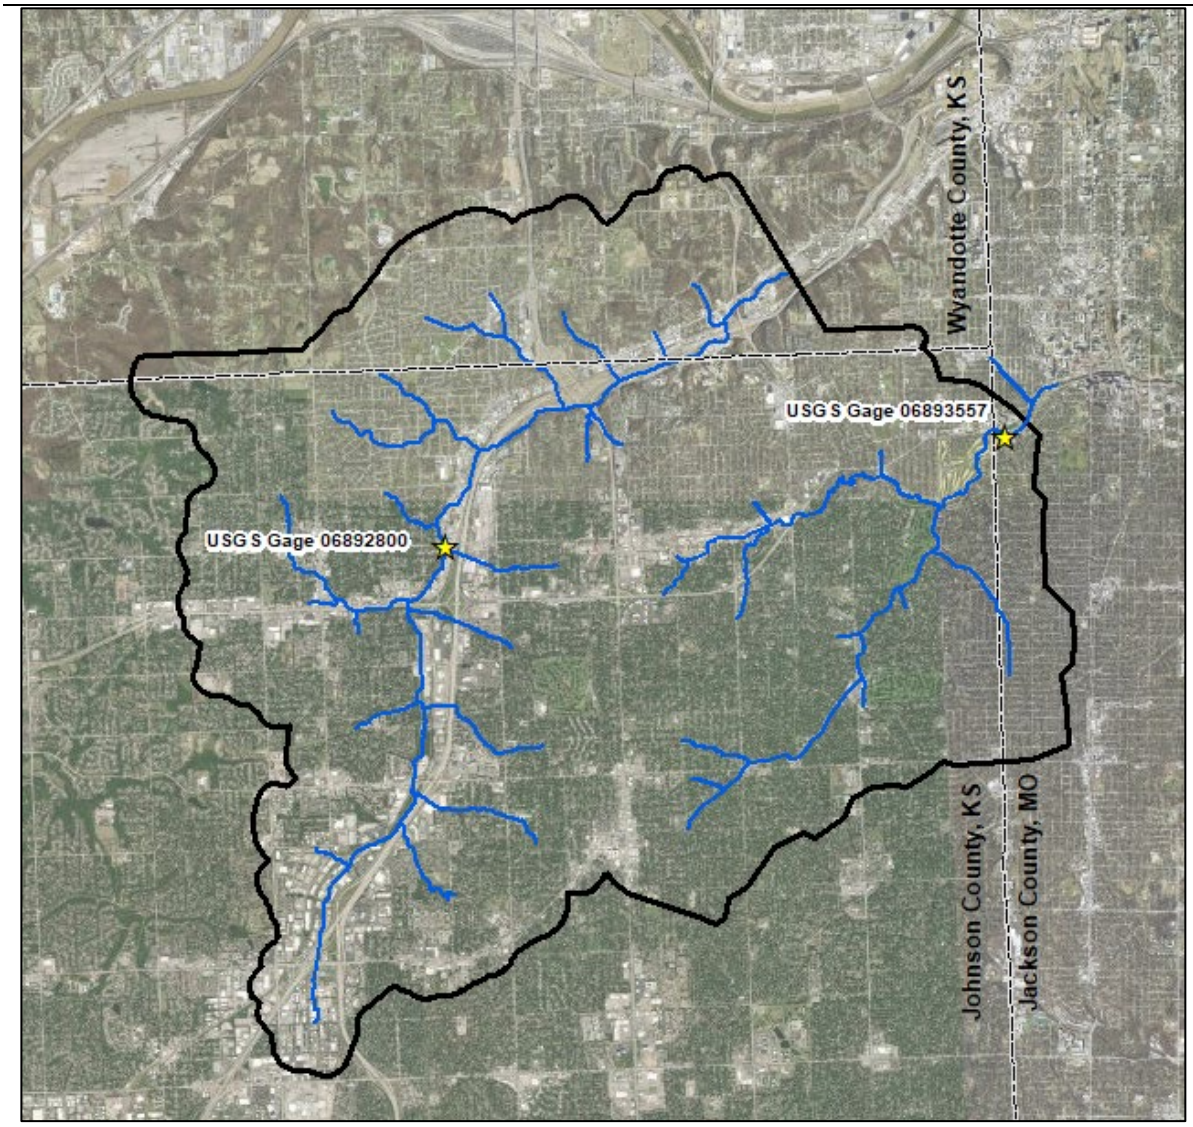

Figure 33: Location of USGS Gages within the Turkey and Brush Creek Watersheds

4.2 Flow Comparison with Regression Estimates & Effective Data

FEMA guidance states that base flood discharges are considered reasonable if they are generally within the prediction error of the regression and gages station estimates. The 1-percent annual chance discharges from the 2D, calibrated models were compared to both the USGS bulletin 17C analysis and regression estimates based on the current document for the state of Kansas (SIR 2017-5063). The prediction of error associated with statistical gage analysis is defined as the upper 84% confidence limit. The standard error of prediction for the Kanas regression equations for Region 1 (where Johnson County falls) is 51.9%.

Flow check locations were developed based on the locations reported in the effective FIS for Johnson County (August 2009) for streams within the Turkey and Brush Creek watersheds. Comparisons between the Effective FIS, Regression, and 2D Models can be found in Table 16 and Table 17, as well as graphically in Figure 29 and Figure 35.

Table 16: 1% Annual Channce Flow Comparison for Turkey Creek Watershed

Stream	Location	DA (sqmi)	1% Annual Chance Discharge (cfs)

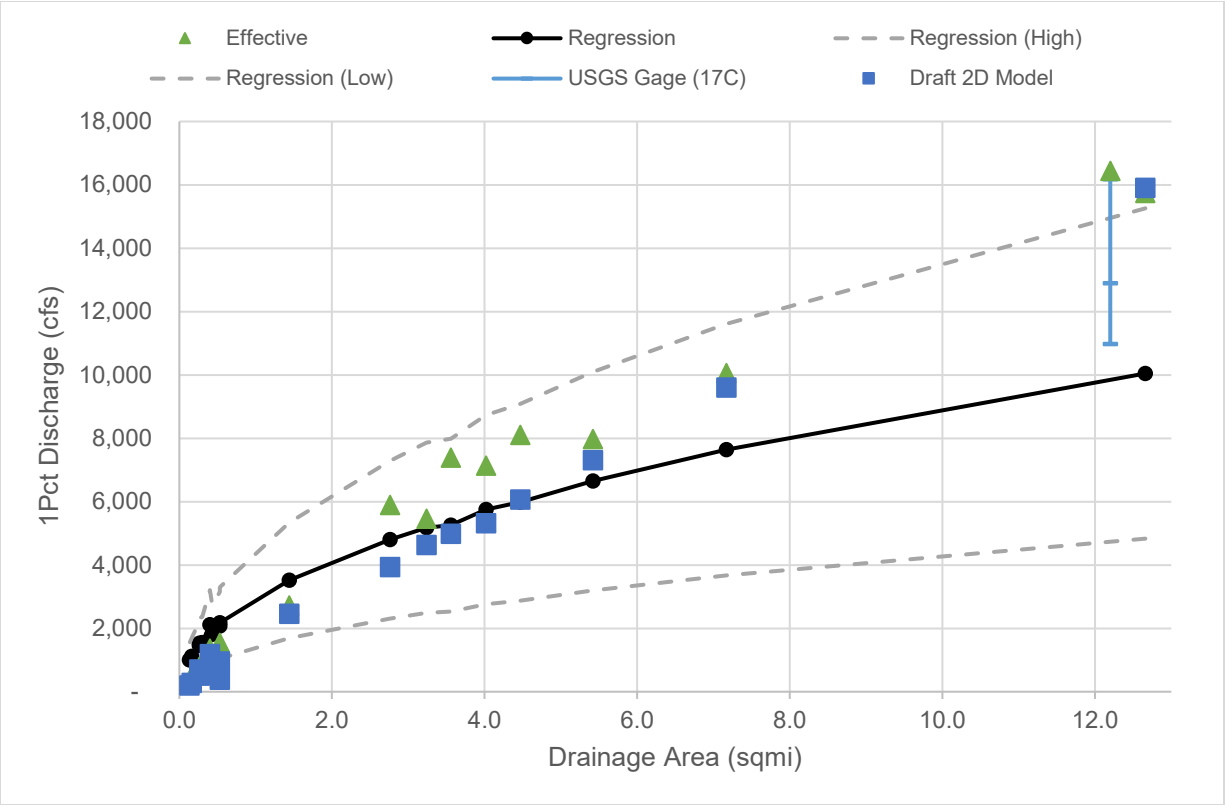

Figure 35: Flow Comparisons for the Brush Creek Watershed

In Turkey Creek, the 2D watershed model with the 12-hour, 3-hr peak nested storm generally produced 1-percent annual chance discharges lower than the effective flood insurance study discharges. The discharges fall within 1 standard error of the Kansas regression equation estimates and within the 84-percent confidence interval of the available USGS gage data along the stream. For the smallest drainage areas reported along Tributary JA, the 2D model produced equal and slightly higher discharges than the effective flows; however, both the 2D model and effective flows are on the lower end of the regression estimates for the smaller drainage areas.

Similarly, the majority of the 1-percent annual chance event flows in the Brush Creek watershed 2D model are lower than the effective flood insurance study discharges but are generally within the standard error of the Kansas regression estimates. At the most downstream portion of the watershed, downstream of the confluence with Rock Creek, the flows along Brush Creek are similar to the effective and slightly higher than the USGS 17C gage analysis. Further investigation was conducted at this location and it was determined that the higher discharge was reasonable for the watershed. The USGS peak flow records are from 1999 to 2023. It does not include the floods of record along Brush Creek from 1977 and 1998.

4.3 Summary of Discharges

The final flows for the Turkey and Brush Creek models are summarized below in Table 18 and Table 19 below.

Table 18: Final Summary of Discharges for Turkey Creek Watershed

Stream	Location	DA (sqmi)	Annual Chance Peak Discharge (cfs)					
			10%	4%	2%	1%	1% +	0.2%

4.4 Stage Comparison

Base flood elevations (BFEs) from the effective digital flood insurance rate map (DFIRM) and the 2D model were compared for streams with effective Zone AE mapping. Water surface elevations from the 2D model were pulled along the stream profile line and plotted with the effective BFEs to compare the two data sources.

Overall, the 2D model results either match the effective BFEs or are slightly lower. Some of the smaller tributaries to Turkey and Rock Creek show lower stages in the 2D model primarily due to a decrease in flows at these locations. Plots for all streams with effective BFEs on the current FIRM for the Turkey and Brush Creek watersheds are in Appendix F and include the following streams:

- Brush Creek
- Turkey Creek
- Turkey Creek Tributary C
- Turkey Creek Tributary F
- Turkey Creek Tributary J
- Rock Creek
- Rock Creek Tributary A
- Rock Creek Tributary B
- Rock Creek Tributary D
- Rock Creek Tributary E

5 Floodplain Mapping

Draft 1- and 0.2-percent annual chance event floodplains will be developed for the study streams. Due to HEC-RAS rain-on-grid methodology, post processing of the floodplain is necessary to remove the pluvial influence that gets reported based on the maximum water surface elevations of the model simulation.

ArcGIS will be used with the maximum water surface elevation outputs to rerender the fluvial flooding elevations associated with the study streams. The post-processing will be completed for the 1- and 0.2-percent annual chance events and will be submitted with the Floodplain Mapping task.

6 Conclusion

The results of the 2D BLE watershed models will be used to develop draft 1-percent and 0.2-percent annual chance floodplains based on the 2-foot resolution LiDAR. These draft floodplains will be included in the floodplain mapping deliverable for Johnson County and will be shared with communities (Lenexa, Overland Park, Prairie Village, Mission Hills, Merriam, Fairway, Mission, Roeland Park,

Westwood, and Westwood Hills) for their review. This data can be used as “best available”. Additional data development and model refinement may be performed based on input from community stakeholders.

Appendix A – Sensitivity Testing

A total of 9 sensitivity scenarios were analyzed to assess the Turkey Creek and Brush Creek watershed sensitivity to the basin parameters. The scenarios are summarized below.

Table A 1: Sensitivity Test Scenarios

	Scenario Name	Parameter Updates
A	High Mann	Update base Manning's n values to high end of recommended values in HEC-RAS Manual (No modification to base CN)
B	Low Mann	Update base Manning's n values to low end of recommended values in HEC-RAS Manual (No modification to base CN)
C	High Mann - Upland Refine	Upland calibration region added with high end of TR-55 sheetflow values (Base Manning's n in floodplain, no modification to base CN)
D	Low Mann - Upland Refine	Upland calibration region added with low end of TR-55 sheetflow values (Base Manning's n in floodplain, no modification to base CN)
E	Low CN	Base CN reduced values by 3 (No changes to Impervious CN 98 or 100, no modification to base Manning's n)
F	High CN	Base CN increased values by 3 (No changes to Impervious CN 98 or 100, no modification to base Manning's n)
G	Ia = 0.1	Abstraction Ratio set to 0.1, base modeling parameters
H	Ia = 0.05	Abstraction Ratio set to 0.05, base modeling parameters
I	Hotstart	Initial conditions added based on the end of simulation results from the 10-pct 12-hr run.

Specific modeling parameter and the adjustments applied for each scenario are summarized in the tables below. The impacts of each scenario were compared at the StormWatch gages where observed data was recorded. These gages only record an observed stage. Additionally, the StormWatch gages are primarily on the mainstem of Turkey Creek. An additional comparison location along Tributary F was included to represent a smaller drainage area. Comparison can be seen in the Figures below.

GENERAL NOTE

THE GEOLOGICAL INFORMATION SHOWN ON THESE PLANS IS FROM STUDIES MADE IN THE FIELD AND REPRESENTS THE BEST INFORMATION AVAILABLE TO THE KANSAS DEPARTMENT OF TRANSPORTATION.

AT BORROW AREA LOCATIONS ADJACENT TO THE RIGHT OF WAY, UTILITY POLES MAY BE SET AT THE PERMANENT LOCATIONS PRIOR TO CONSTRUCTION AS APPROVED BY THE ENGINEER PROVIDED A MINIMUM VERTICAL CLEARANCE, IN ACCORDANCE WITH THE NATIONAL ELECTRICAL SAFETY CODE, IS OBTAINED. THE CONTRACTOR WILL BE REQUIRED TO WORK AROUND THESE POLES TO COMPLETE THE WORK.

ALL BORROW TO BE OBTAINED FROM AREAS PROVIDED BY THE CONTRACTOR SHALL BE APPROVED BY THE ENGINEER, BOTH AS TO SUITABILITY OF MATERIAL AND SITE LOCATION, LOCATIONS WHICH, IN THE OPINION OF THE ENGINEER, CONTAIN UNSUITABLE MATERIAL OR WILL LEAVE AN UNSIGHTLY APPEARANCE ON THE PROJECT WILL NOT BE APPROVED.

CHANNELS SHALL BE CUT AT BOX CULVERTS (UNLESS OTHERWISE NOTED) TO FLOW LINE ELEVATIONS AND TO A WIDTH OF ONE FOOT OUTSIDE OF EACH OUTSIDE WALL AND WITH SLOPES 2 TO 1 PRIOR TO CONSTRUCTION OF THE CULVERT.

EMBANKMENT QUANTITIES FOR INITIAL CONSOLIDATION AND SETTLEMENT SHOWN IN THE EARTHWORK QUANTITIES ARE SUBSIDIARY TO OTHER EARTHWORK ITEMS. MATERIAL FOR THE EMBANKMENT IS INCLUDED IN THE EXCAVATION QUANTITIES.

EXCAVATION REQUIRED FOR PLACING SELECT SOIL IS INCLUDED IN THE COMMON EXCAVATION QUANTITIES.

WHERE EASEMENTS ARE SHOWN ON RAILROAD RIGHT OF WAY, THE CONTRACTOR SHALL BE REQUIRED TO WORK AROUND AND NOT DISTURB THE RAILROAD COMMUNICATION OR SIGNAL POLES OR LINES.

EXCAVATION SHOWN TO BE WASTED SHALL BE WASTED ON SITES PROVIDED BY THE CONTRACTOR. THESE SITES SHALL BE APPROVED BY THE ENGINEER AS TO SUITABILITY, APPEARANCE, AND SITE LOCATION. LOCATIONS THAT, IN THE OPINION OF THE ENGINEER, WILL LEAVE AN UNSIGHTLY APPEARANCE WILL NOT BE APPROVED.

ALL TREES, HEDGE ROWS, SHELTERBELTS, AND WOODY SHRUBS NOT SHOWN TO BE REMOVED AND LOCATED BETWEEN THE CONSTRUCTION LIMITS AND THE RIGHT-OF-WAY LINE OR EASEMENT LINE SHALL BE SPARED UNLESS DIRECTED BY THE ENGINEER TO BE REMOVED. ALL TREES WINTHIN THE APPROPRIATE CLEAR ZONE SHALL BE REMOVED.

Revised Plans

GENERAL NOTES

CONSTRUCTION SPECIFICATIONS: All work shall be in accordance with the current edition of the Standard Specifications for State Road and Bridge Construction, Kansas Department of Transportation.

LOW AREA: This item shall consist of all labor, materials and equipment necessary to fill the area indicated on the "Construction Layout" sheet and shall be included in the bid item "Concrete (Grade 4.0)(AE)".

Clean and power wash the limestone under the Low Area as required to remove organic material. This shall be subsidiary to the bid item "Concrete (Grade 4.0)(AE)"

The top surface shall be sloped at a min of 4% towards the center of the channel and shall be roughened to produce 1" tall protrusions with a maximum of 3" clear between protrusions.

RETAINING WALL (MODULAR CONCRETE): This item shall consist of all labor, materials and equipment necessary to install 2'-6" (H) x 5'-0" (L) x 2'-6" (W) modular concrete blocks. The concrete blocks shall have an approved interlocking system and shall be fabricated from Concrete (Grade 2.5)(AE) and shall be paid for per square foot of wall face.

The leveling pad shall be constructed from Concrete (Grade 4.0) (AE). All material, labor and equipment necessary to construct the leveling pad and remove, repair and/or replace grouted riprap, shall be subsidiary to the bid item "Retaining Wall (MBW)."

WEIR WALL: This item shall consist of all labor, materials and equipment necessary to construct the weir wall as detailed on the "Weir Wall Plan and Details" sheet and shall be included in the bid item "Concrete (Grade 4.0)(AE)". All reinforcing steel required in the weir wall shall be paid for under the bid item " Reinforcing Steel (Grade 60)".

Clean and power wash area where weir wall is to be installed as required to remove all organic material and roughen existing limestone prior to placing concrete. This shall be subsidiary to the bid item "Concrete (Grade 4.0)(AE)".

The horizontal and sloped surfaces of the weir wall shall be roughened to produce 1" tall protrusions with a maximum of 3" clear between protrusions.

CORE DRILLING: This item shall consist of all labor, material and equipment necessary to core drill the fill holes and install the casing and cap and shall be subsidiary to the bid item "Concrete (Grade 4.0)(AE)".

CONCRETE: Bevel all exposed edges of all concrete with a 3/4-inch triangular molding, except where noted on the plans.

SELF CONSOLIDATING CONCRETE: All concrete designated as self consolidating concrete shall meet "Section 401" of the Standard Specifications "AND" the following requirements:

Quality Assurance:

A pre-job conference will be held at the jobsite to discuss site specific conditions. Those present shall include the Ready Mix Supplier, the Contractor, the Engineer and the Testing Agency. No self consolidating concrete placement will be allowed prior to this meeting.

The self consolidating concrete manufacturer shall make available a qualified individual to monitor concrete quality and performance as specified.

Slump Flow Characteristics:

The self consolidating concrete slump flow characteristics required shall be determined by the manufacturer and shall be included in the mix design.

The slump flow characteristics shall be measured per ASTM C1611.

Mockup:

The General Contractor, Concrete Sub-Contractor, Ready-Mix Supplier and Testing Agency shall submit a mock up procedure, that simulates field conditions as closely as possible, to the engineer for approval. Once approved, the concrete shall be placed and tested according to the approved procedure. No self consolidating concrete placement will be allowed until the mockup is placed, reviewed and approved by the Engineer.

Surface Preparation:

Immediately before concrete placement, thoroughly wet moisture-absorbing material that will be in contact with the concrete, without developing standing water. Ensure that concrete steel forms and rebars are not steaming hot prior to pouring concrete.

REINFORCING STEEL: All reinforcing steel dimensions are to the centerline of bars unless otherwise noted. All reinforcing steel shall conform to the requirements of ASTM A615, Grade 60.

EXISTING DIMENSION VERIFICATION: Verify, by field measurement, the as built dimensions of the existing structure and submit such verification in writing to the Engineer. The verification will include sketches, drawings, photographs and descriptions as needed to clearly define the as built dimensions that will be incorporated in the new construction.

CONCRETE SURFACE REPAIR: Remove loose and unsound wall and top slab concrete as designated by the Engineer to whatever depth is necessary to reach sound concrete. See KDOT Specifications.

All materials removed from the existing structure shall become the property of the Contractor and removed from the site.

AREA PREPARED FOR PATCHING: Remove loose and unsound bottom slab concrete as designated by the Engineer to whatever depth is necessary to reach sound concrete. See KDOT Specifications.

All materials removed from the existing structure shall become the property of the Contractor and removed from the site.

BROKEN CONCRETE: Waste broken concrete and debris removed from the existing structure on sites provided by the Contractor and approved by the Engineer.

UTILITIES: Field verify locations of all utilities adjacent to the structure prior to the start of construction. Care shall be taken to avoid damage to existing utilities or their conduit encasements. Damage to existing utilities shall be repaired at the Contractor's expense.

QUANTITIES: Items not listed separately in the Summary of Quantities are subsidiary to other items in the proposal.

DIMENSIONS: All dimensions shown on the design plans are horizontal dimensions unless otherwise noted. Make necessary allowances for roadway grade and cross slope.

⚠1 SHOT-CRETE: This item shall consist of all labor, materials and equipment necessary to fill the areas indicated on the "Weir Wall Plan and Details" sheet and shall be paid for per square feet as "Concrete Surface Repair".

Tree removal as shown on the plan is included in the bid item "Clearing and Grubbing".

RECAPITULATION OF BRIDGE QUANTITIES		
ITEM	QUANTITY	UNIT
Concrete (Grade 4.0)(AE)	142.1	cu.yd.
Reinforcing Steel (Grade 60)	14600	lbs.
Reinforcing Steel (Repair)(Grade 60)(Set Price)	1	lbs.
Area Prepared for Patching (Partial Depth)	10	sq.yd.
Area Prepared for Patching (Full Depth)	5	sq.yd.
⚠1 Concrete Surface Repair	~~170~~ 933	sq.ft.
Riprap (Heavy Stone) (1/4 ton)	55	cu.yd
Bedding for Slope Protection	18	cu.yd.
Retaining Wall (MBW)	113	sq.ft.
⚠1 ~~Shot Crete~~	~~763~~ 0	~~sq.ft.~~

Concrete (Grade 4.0)(AE) f'c = 4 ksi
Reinforcing Steel(Grade 60) fy = 60 ksi

CONSTRUCTION SEQUENCE

These plans have been developed based on a sequence of construction for completing the RCB repairs as follows:

1. Patch the delaminated areas of top slab, bottom slab and walls of all cells, full length of the existing RCB.
2. Core Fill Holes through the pavement at the spacing shown to allow placement of self consolidating concrete for the Top Slab Repair. Spacing of fill holes shown is based on information from area self consolidating concrete producers and contractors to meet traffic handling constraints and provide a quality finished product.
   a. Fill holes to be cased and capped during construction to prevent loss of material into the RCB and debris from falling into top slab formwork.
   b. After completion of Top Slab Repairs, fill hole casings will be removed to 12" below finish pavement and holes will be patched.
3. Construct the 6" wall in the east cell of the RCB prior to placement of the top slab in that cell.
4. Prepare reinforcing and formwork/falsework for the completion of Top Slab Repairs.
5. Construct the Top Slab Repairs - to be completed in one night of work. See Construction Sequencing and Traffic Control Plans for permissible lane closures

CONCRETE PLACING SEQUENCE: The Contractor shall submit a placing sequence for review, see Construction Sequencing and Traffic Control Plans for permissible lane closures. Submit the placing sequence to the Engineer at the Preconstruction Conference. Include the proposed rate of concrete placement in C.Y./h, the plant capacity, placement direction, construction joint location, a description of the equipment used in placing the concrete, proposed admixtures, and the quantity of concrete in each placing segment. Any additional cost for the Contractor's plan of placing concrete, including admixtures, shall be at the Contractor's expense and shall be considered subsidiary to the bid item "Concrete (Grade 4.0) (AE)". Approval of the Contractor's sequence is required prior to placement of concrete in the slab.

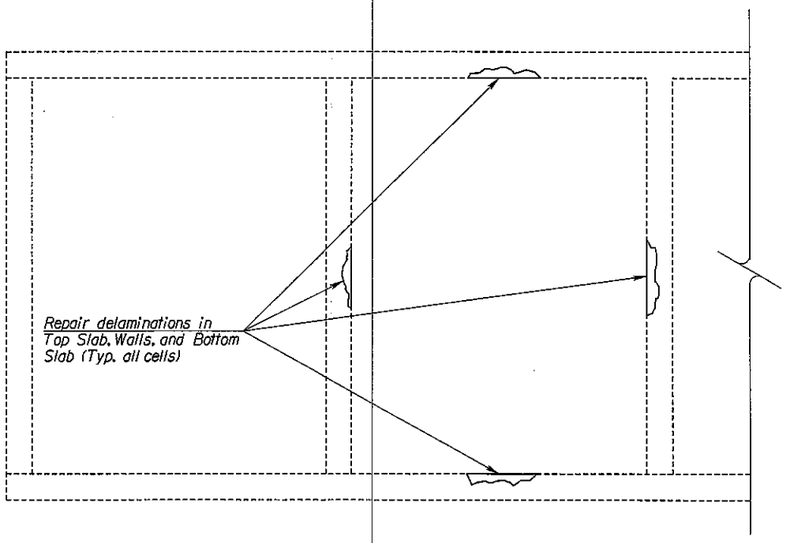
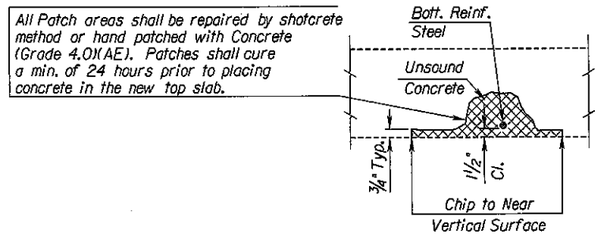
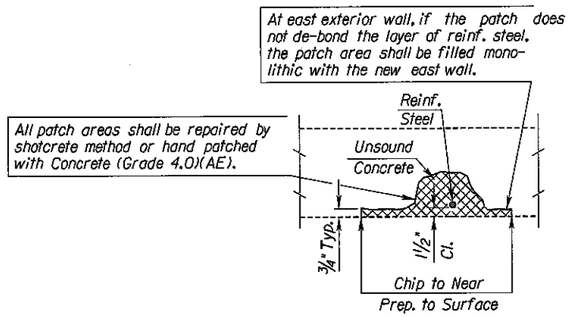
PART PLAN SHOWING SLAB & WALL PATCHING SEQUENCE



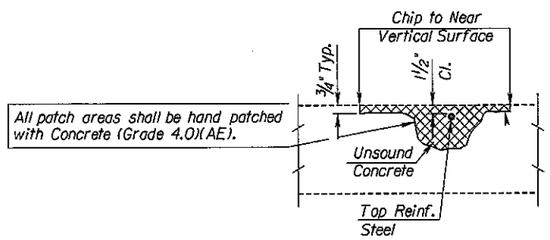
PART SECTION SHOWING PATCHING



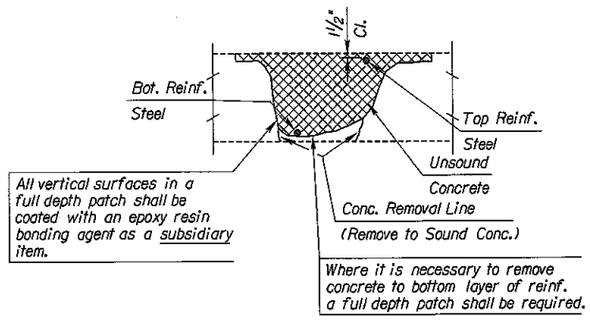
TOP SLAB PATCHING DETAIL



WALL PATCHING DETAIL



PARTIAL DEPTH FLOOR PATCH



FULL DEPTH FLOOR PATCH

GENERAL NOTES

PATCHING SEQUENCE: The concrete removal shall be completed in stages. Concrete removed in one cell of the RCB shall be patched prior to beginning concrete removal in adjacent cells. Maximum width along centerline of RCB of concrete removal with debonded reinforcing shall be 2'-0" (Area ①) with a minimum 4'-0" width (Area ②) between open areas (Area ①). Concrete removal shall not begin in Area ② until the patching concrete in adjacent Area ① has cured a minimum of 3 days.

CONCRETE SURFACE REPAIR: This item shall consist of removing unsound concrete and patches from the top slab & walls of the RCB, cleaning reinforcing bars, and filling the removed patched areas with concrete. Quantity shown is an estimate of the areas involved. The exact areas shall be determined by tapping, before, during and after chipping operation to assure that all unsound concrete has been removed. See KDOT Specifications.

The areas to be patched above the new top slab construction shall be determined by the Engineer. Areas showing distress but still capable of staying intact during construction of the new top slab need not be patched.

AREA PREPARED FOR PATCHING: This item shall consist of removing unsound concrete and patches from the bottom slab of the RCB, cleaning reinforcing bars, and filling the removed patched areas with concrete. Quantity shown is an estimate of the areas involved. The exact areas shall be determined by tapping, before, during and after chipping operation to assure that all unsound concrete has been removed. See KDOT Specifications.

FULL DEPTH PATCHING: See KDOT Specifications for method of measurement and basis of payment.

REINFORCING: Care should be exercised to prevent cutting, stretching or damaging exposed reinforcing steel. Extreme care should be exercised to avoid breaking the bond between the reinforcing steel and concrete where bars are partially exposed yet remain anchored in sound concrete. Reinforcing steel damaged, cut or deteriorated shall be replaced as directed by the Engineer. See table on General Notes sheet for minimum splice length required. Replacement of bars damaged by the Contractor shall be done so at the Contractors expense.

SUMMARY OF PATCHING QUANTITIES		
ITEM	QUANTITY	UNIT
Reinforcing Steel (Repair)(Grade 60)(Set Price)	1	lbs.
Area Prepared for Patching (Partial Depth)	10	sq.yd.
Area Prepared for Patching (Full Depth)	5	sq.yd.
Concrete Surface Repair	170	sq.ft.

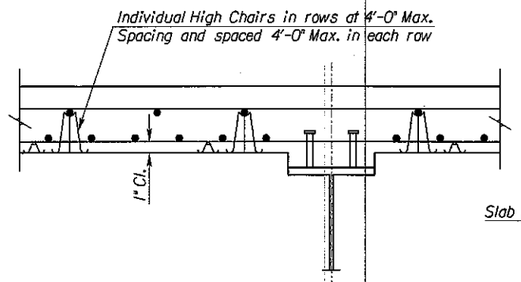
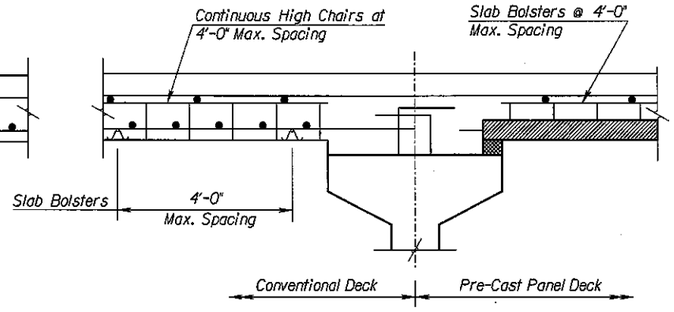
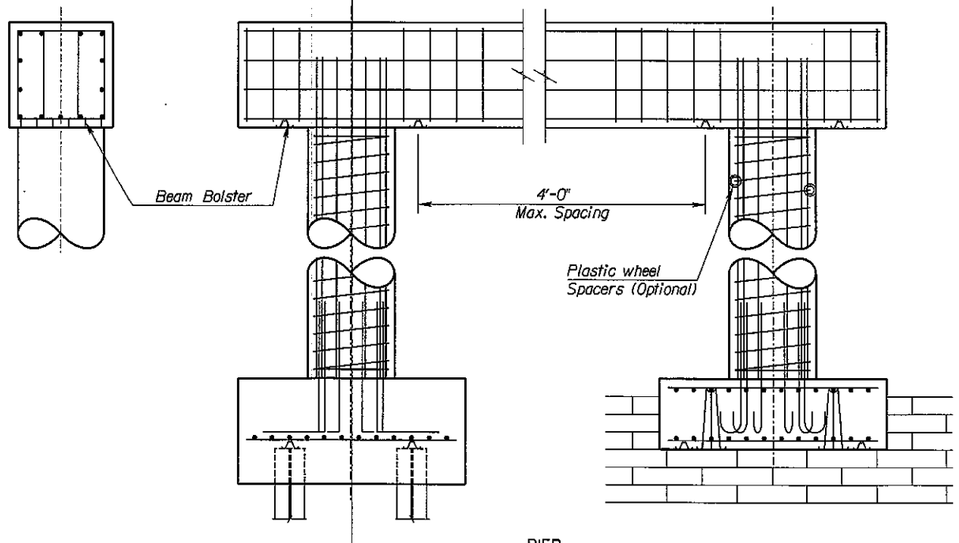
CONTINUOUS HAUNCHED SLAB

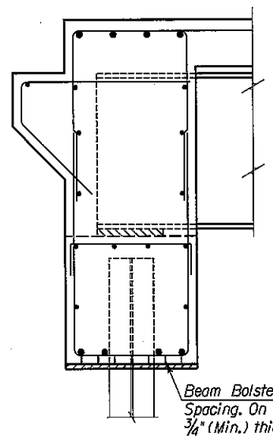




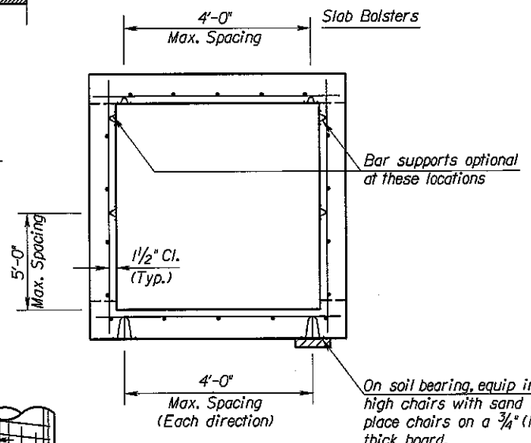
DECK GIRDERS



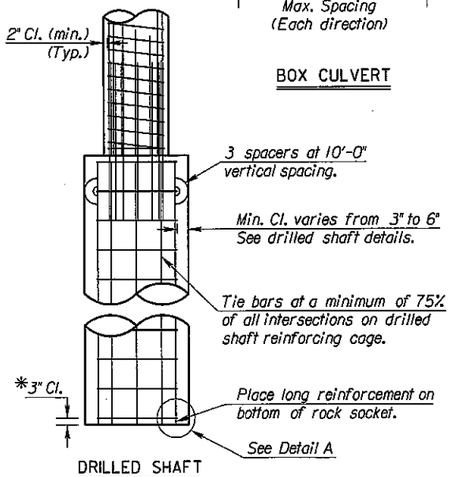
PIER



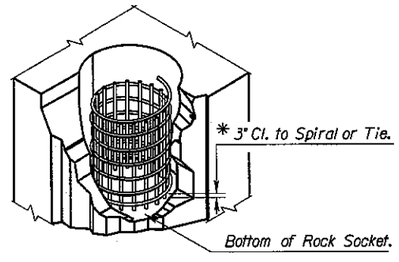
ABUTMENT



BOX CULVERT



DRILLED SHAFT



DETAIL A

* Note: Longitudinal reinforcing steel is placed on the bottom of the rock socket. Maintain 3" clearance from the bottom of rock socket to the first spiral or tie bar.

TYPICAL SECTION

Reference is made to the latest edition of the CRSI "Manual of Standard Practice" for recommended industry practices concerning reinforcing steel.

Use only the following types of bar supports:

1) Wire Bar Supports:

a) Epoxy coated reinforcing: Class I Protection
b) Non-epoxy coated reinforcing: Class 1, 2, or 3 Protection

2) Plastic Bar Supports

3) Supplementary bars

When securing epoxy coated reinforcement, use tie wires or metal clips that are epoxy or plastic coated.

Do not weld reinforcing steel to bar supports or to other reinforcing steel. Shop weld spacer frames for haunched slabs.

Tie bars at all intersections around the perimeter of each mat and at not less than 2'-0" centers or at every intersection, whichever is greater.

Where more than one length of bar support is required, lap the end legs so they are locked or tied together.

Use proper height supports to maintain the distance between the reinforcing and the formed surface or the top surface of deck slabs within 1/4" of that indicated on the plans.

Spacings shown are maximums. Use sufficient supports, as determined by the Engineer, to retain the reinforcing steel in position.

Construct any platforms, required for the support of workers and/or equipment during concrete placement, directly on the forms and not on the reinforcing steel.

Designs and arrangements of Supports or Spacers other than as shown on this sheet, may be used with the permission of the Engineer.

STATE	PROJECT NO.	YEAR	SHEET NO.	TOTAL SHEETS
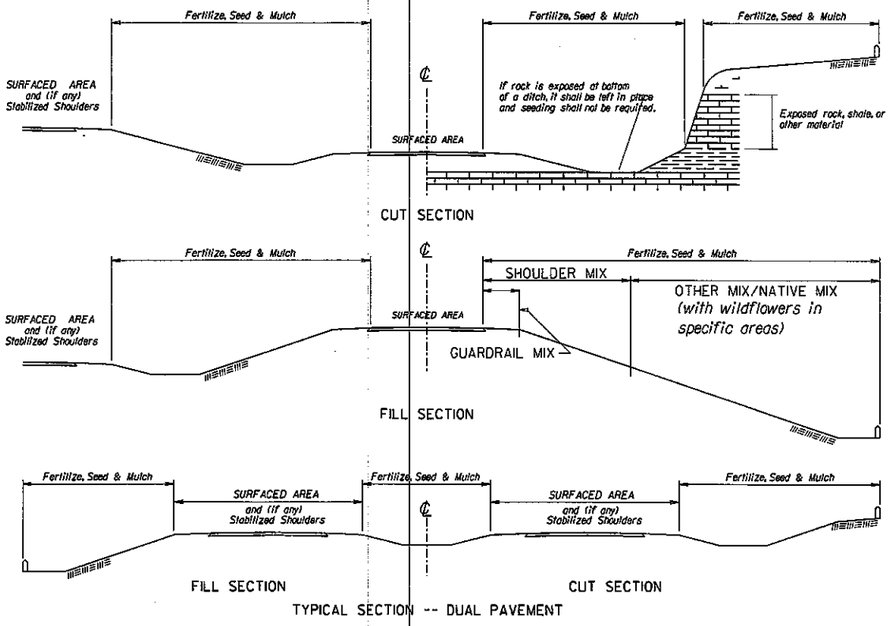
KANSAS	46 N-0425-01	2010	13	33



SEEDING PERIODS

COOL SEASON February 15 to April 20 and August 15 to Sept. 30	WARM SEASON November 15 to June 1
SPECIES	SPECIES
Bluegrasses	Bluestems
Bromegrasses	Buffalograss
Canada Wildrye	Eastern Gamagrass
Fescues	Gramas
Ryegrasses	Indiangrass
Wheatgrasses	Lovegrasses
Reed Canarygrass	Switchgrass
	Wildflower Mixes

When "Cool Season" species are mixed with "Warm Season" species, in areas of 1 acre or more, the mixture shall be seeded during the "Warm Season". In areas of less than 1 acre, the mixture of "Cool Season" and "Warm Season" species may be seeded during the "Warm or Cool Seasons".

SODDING PERIODS

March 1 to April 15
and
September 1 to November 15

GENERAL: The entire disturbed area, excepting the paved or surfaced areas, steep rocky slopes and areas of undisturbed native sod or other desirable vegetation shall be fertilized (limed when required), seeded, and mulched. Soil preparation shall conform to the Standard Specifications except as noted below.

All borrow areas shown on the plans are to be fertilized, seeded, and mulched. However, operation in borrow areas where crops are growing may be omitted when requested by the owner.

It shall not be required to till the area to bare ground prior to permanent seeding. If temporary cover has provided stable slopes with no erosion, seed the permanent grasses into the existing cover. If there has been erosion that requires repair prior to seeding, then it may be necessary to regrade the area, resulting in bare ground.

FERTILIZER: A ratio and application rate that equals or exceeds the required minimum rate per acre of N, P_2O_5, K_2O listed in Summary of Seeding Quantities will be acceptable.

MULCHING: Mulch shall be spread uniformly over all disturbed areas and punched in the soil, unless otherwise noted on the plans. The rate of application per acre, thickness in place, for the mulching material is as follows:

1¾ - 2¼ Tons per Acre = 1½" loose depth spread uniformly over acre.

Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.

Other vegetative mulches (Acceptable only with the Engineer's concurrence).

The above rate is a guide. It will be at the discretion of the Engineer to determine what rate is sufficient for adequate protection of newly seeded areas.

The amount of mulch in the bid quantities is estimated. The total mulch required shall be determined in the field. The bid item for mulching shall be paid for by one of the following ways: A) Plan quantity as shown on Summary of Quantities, Seeding Sheet or Water Pollution Control Sheet, B) Slope measurement as measured in field, or C) Drill measurement less 5% as measured at the time of seeding.

Package and deliver the wildflower seed separately from the grass seed mix. Package and deliver the Tall Drop Seed separately from the grass seed and the wildflower mix. Place the grass seed (except Tall Drop Seed) in the large seed box and drill (cover) seed ⅛"-¼". Place the wildflower seed in a separate seed box and drill (cover) seed 1/16" maximum. Place the Tall Drop Seed in a separate (third) seed box and place the seed (using the seed drill) on the soil surface. OPTION: Broadcast Tall Drop Seed on the soil surface.

SUMMARY OF SEEDING QUANTITIES

P.L.S. RATE/ACRE				ACRES				BID ITEM	QUANTITY	UNIT
SHLDR	OTHER			SHLDR	OTHER					
	100				0.20			Fertilizer (15-30-15)		
	180				0.20			Seed (Turf Type Tall Fescue Seed Blend)		
								Seeding	Lump Sum	L.S.
								Mulching (Permanent) (Set Price)		ac

SHLDR = Shoulder Turf Mix: Includes a 30 foot wide strip along the stabilized shoulder on each side of each traveled way, plus all median areas less than 60 feet wide.

OTHER = All other turf areas except Shoulder, Guardrail, and Native areas usually include the Native Wildflower Mix.

GRDRL = Guardrail Mix: This mix does not need mowing. Plant it below the guardrail between the edge of pavement and the edge of the 10:1 slope, and on steep slopes or non-mowable slopes as shown on the drawings.

NATIVE = The Native Mix is a 40% wildflower, 60% native grass mix. See this sheet for the locations of this high wildflower content seed mix.

NOTE: Projects of less than 1 acre shall be bid as "Seeding" by the lump sum. All disturbed areas shall be seeded, fertilized and mulched at the listed rate per acre. The acres are estimated.

TYPICAL SECTION -- DUAL PAVEMENT

GENERAL: The entire disturbed area, excepting the paved or surfaced areas, steep rocky slopes and areas of undisturbed native sod or other desirable vegetation shall be fertilized (limed when required), seeded, and mulched. Soil preparation shall conform to the Standard Specifications.

Temporary seeding shall be done during any time of the year that the soil can be cultivated. After the temporary seeding has been completed on the entire project, a permanent seeding shall be done by another project during the normal seeding season.

MULCHING: Mulch shall be spread uniformly over all disturbed areas and punched in the soil, unless otherwise noted on the plans. The rate of application per acre, thickness in place, for the mulching materials is as follows:

1¾ - 2¼ Tons per Acre = 1½" loose depth spread uniformly over acre.

Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.

Other vegetative mulches acceptable only with the Engineer's concurrance.

The above rate is a guide. It will be at the discretion of the Engineer to determine what rate is sufficient for adequate protection of newly seeded areas.

The amount of mulch and mulch tacking slurry in the bid quantities is estimated. The total mulch and mulch tacking slurry required shall be determined in the field. The bid item for mulching and mulch tacking slurry shall be paid for by one of the following ways: A) Plan quantity as shown on Summary of Quantities, Seeding Sheet or Water Pollution Control Sheet, B) Slope measurement as measured in field, or C) Drill measurement less 5% as measured at the time of seeding.

SUMMARY OF SEEDING QUANTITIES: PROJECTS OF 1 ACRE OR MORE

SOIL EROSION MIX

PLS RATE	NAME	QTY (lb)
	Total (lb)	

FERTILIZER: A ratio and application rate that equals or exceeds the required minimum rate per acre of N, P_2O_5, K_2O listed in Summary of Quantities will be acceptable.

- * - N = Nitrogen Rate of Application
- ** - P_2O_5 = Phosphorous Rate of Application
- *** - K_2O = Potassium Rate of Application

The Contractor will be required to finish areas of excavation, borrow and embankment in accordance with the specifications. Areas that require installation or construction of temporary water pollution control items will be finished in reasonable close conformity to the alignment, grade and cross section shown on the plans or as established by the Engineer.

NOTE: Projects of less than 1 acre shall be bid as "Seeding" by the lump sum. All disturbed areas shall be seeded, fertilized and mulched at the listed rate per acre. The acres are estimated.

CLT = Construction Limit Tract. This area does not include the channel/slope area and shall be seeded in accordance with the chart to the right.

Channel = This is the area that shall be seeded prior to placement of the Erosion Control. Broadcasting seed is preferred, however, drilling is acceptable

Slope = This is the area that shall be seeded prior to placement of the Erosion Control. Broadcasting seed is preferred, however, drilling is acceptable.

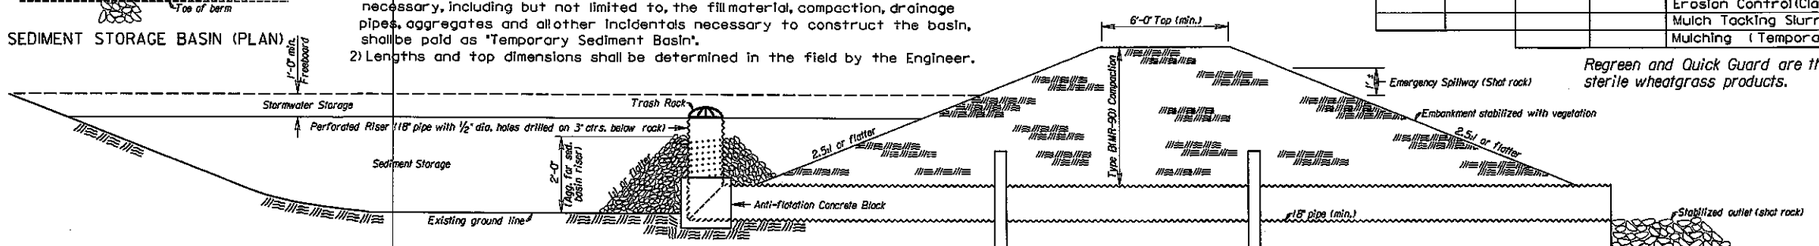
CONCRETE ANTI-SEEP COLLAR

NOTES:
1) Temporary Sediment Basins shall be constructed at locations as directed by the Engineer or as approved in the SWPPP Schedule. All work and materials necessary, including but not limited to, the fill material, compaction, drainage pipes, aggregates and all other incidentals necessary to construct the basin, shall be paid as "Temporary Sediment Basin".
2) Lengths and top dimensions shall be determined in the field by the Engineer.



SEDIMENT STORAGE BASIN (ELEVATION)

SUMMARY OF SEEDING QUANTITIES: PROJECTS LESS THAN 1 ACRE

P.L.S. RATE/ ACRE		ACRES		BID ITEM	QUANTITY	UNIT

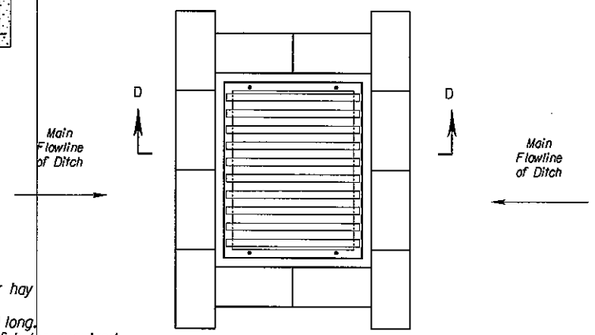
SECTION D - D

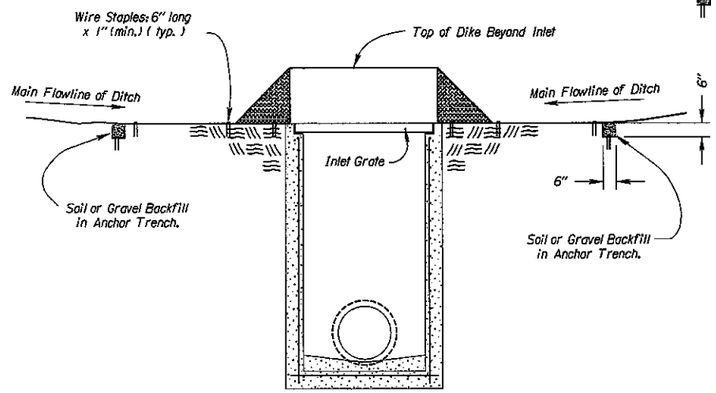


PLAN

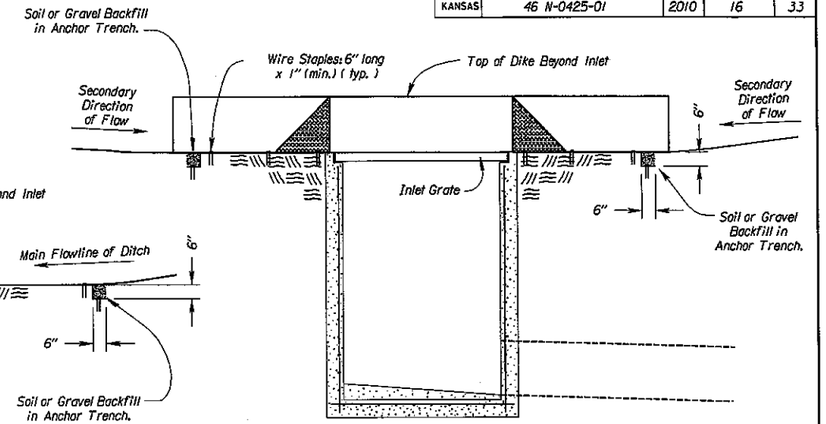
NOTES:

The use of Straw or Hay Bales, Silt Fence or Triangular Silt Dike for Temporary Inlet Sediment Barrier is at the option of the Contractor.

Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.



SECTION A - A



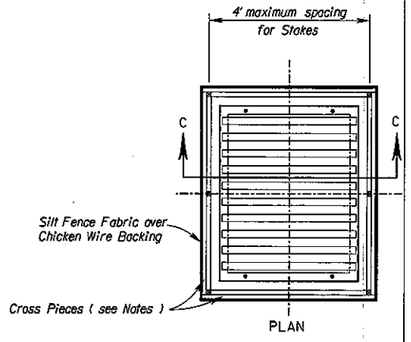
SECTION B - B

STRAW OR HAY BALES:

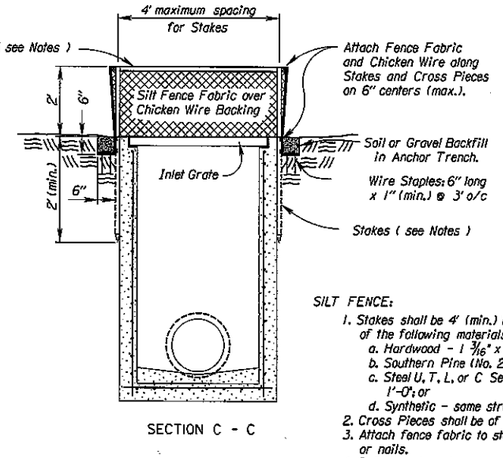
1. *Place bales tightly together, with loose straw or hay wedged between bales to close off openings.*
2. *Wood stakes shall be 2" x 2" (nom.) x 4' (min.) long.*
3. *Refer to plans sheets to estimate the number of bales required.*
4. *Use only twine to bind bales. The use of wire binding is prohibited because it does not readily biodegrade.*

TEMPORARY INLET SEDIMENT BARRIER
(STRAW OR HAY BALE METHOD)

NO SCALE



PLAN



SECTION C - C

SILT FENCE:

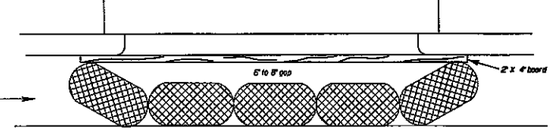
1. *Stakes shall be 4' (min.) long and of one of the following materials:*
   a. *Hardwood - 1 3/16" x 1 3/16";*
   b. *Southern Pine (No. 2) - 2 5/8" x 2 5/8";*
   c. *Steel U, T, L, or C Section - 1.33 lbs. per 1'-0"; or*
   d. *Synthetic - same strength as wood stakes.*
2. *Cross Pieces shall be of same material as Stakes.*
3. *Attach fence fabric to stakes with staples, wire or nails.*
4. *Refer to plan sheets to estimate the length of Silt Fence required.*

TEMPORARY INLET SEDIMENT BARRIER
(SILT FENCE METHOD)

NO SCALE

Bags = synthetic net (3mm mesh) or burlap bags (24" long by 12" wide)

Rock = approximately 1" to 2" diameter



CURB INLET PROTECTION

1. *Place gravel bags such that no gaps are evident.*
2. *Height of bags must not be above top of curb.*
3. *Alternative products may be used other than gravel bags such as the "Gutter Buddy". Products must be approved by the Engineer.*

INSTALLATION NOTES

STRAW OR HAY BALES:

1. Place bales tightly together, with loose straw or hay wedged between bales to close off openings.
2. Wood stakes shall be 2" x 2" (nom.) x 4' (min.) long.
3. Refer to plans sheets to estimate the length of bales required.
4. Use only twine to bind bales. The use of wire binding is prohibited because it does not readily biodegrade.

SILT FENCE:

1. Stakes shall be 4' (min.) long and of one of the following materials:
   a. Hardwood - 1 3/16" x 1 3/16";
   b. Southern Pine (No. 2) - 2 5/8" x 2 5/8";
   c. Steel U, T, L, or C Section - 1.33 lbs. per 1'-0"; or
   d. Synthetic - same strength as wood stakes.
2. Attach fence fabric to stakes with staples, wire or nails.
3. Refer to plan sheets to estimate the length of Silt Fence required.

BIODEGRADABLE LOG BARRIERS

1. Place biodegradable logs tightly together.
2. Wood stakes shall be 2" x 2" (nom.) x 4' (min.) long.
3. Wire staples shall be 6" long x 1" wide (min.) and placed on 3' (max.) centers.
4. Refer to plan sheets to estimate length of biodegradable log barriers required.

Biodegradable Logs, Straw Wattles & Sediment Logs

		PRODUCT		
		9" Sediment Log & 9" Straw Wattle (ft)	12" Sediment Log & 12" Straw Wattle (ft)	20" Sediment Log & 20" Straw Wattle (ft)
Slope Gradient	≤4H:1V	40	60	80
	3H:1V	30	45	60
	2H:1V	20	30	40
	1H:1V	10	15	20

9" and 12" material should only be used in areas which have been seeded and mulched. 20" material should be used in all other areas. Deviations should be approved by the Field Engineer.

GENERAL NOTES

1) The use of Straw or Hay Bales, Silt Fence or Biodegradable Logs is at the option of the Contractor.
2) The slope barriers shall be placed along contour lines, with a short section turned upgrade at each end of the barrier. The maximum length of the slope barrier shall not exceed 250 feet, and the barrier ends need to be staggered.
3) At culverts, the Straw or Hay Bales or Silt Fence shall be placed over the culvert, not through the streambed flowline.
4) Barriers damaged by Contractor's negligence, including improper maintenance or lack of maintenance, shall be repaired immediately by Contractor at no additional cost to KDOT.
5) Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.

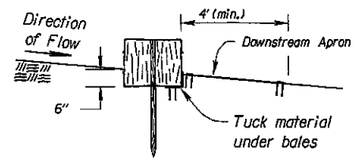
SECTION A-A



SECTION B-B

STRAW OR HAY BALE DITCH CHECK

NO SCALE

STRAW OR HAY BALE NOTES:

1. Place bales tightly together, with loose straw or hay wedged between bales to close off openings.
2. Wood stakes shall be 2" x 2" (nom.) x 4' (min.) long.
3. Use as many bales as necessary to completely block the ditch and to prevent water from flowing around the ends of the ditch check.
4. Use only twine to bind bales. The use of wire binding is prohibited because it does not readily biodegrade.
5. Use silt fence material as the downstream apron to prevent scour below the ditch check.
6. Wire staples shall be 6" long by 1" wide, minimum.

GENERAL NOTES:

1) The choice of ditch check methods is at the option of the Contractor.
2) Use only rock checks in situations where the ditch slope exceeds 6 percent.
3) Ditch checks damaged by Contractor's negligence, including improper maintenance or lack of maintenance, shall be repaired by Contractor at no extra cost to KDOT.
4) Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.

TEMPORARY DITCH CHECK SPACING

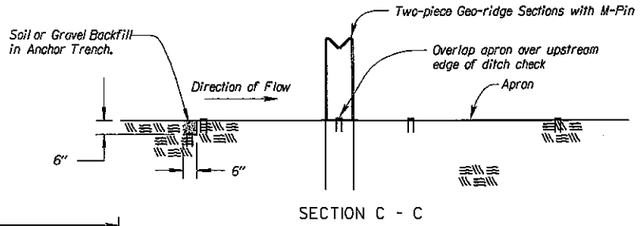
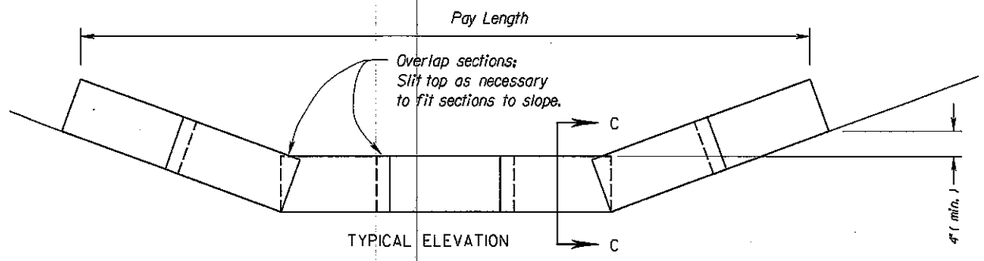
GEO-RIDGE PERMEABLE BERM NOTES

1. Overlap Geo-ridge Berm sections and apron material by 6".
2. Use M-Pins supplied by manufacturer to secure geo-ridge Berm sections.
3. Use as many Geo-ridge Berm sections as necessary to insure water does not flow around end of ditch check.
4. Use silt fence material as the apron to prevent scour above and below the ditch check.
5. Wire Staples shall be 6" long by 1" wide, minimum.



SECTION C - C



GEO-RIDGE PERMEABLE BERM DITCH CHECK

NO SCALE

ROCK DITCH CHECK NOTES

1. Rock shall be clean aggregate, D50 = 6".
2. Place rock in such manner that water will flow over, not around ditch check.
3. Do not use rock ditch checks in clear zone.
4. Excavation: The ditch area shall be reshaped to fill any eroded areas. Prior to placement of the rock, the ditch shall be excavated to the dimensions of the Rock Ditch Check and to a minimum depth of 6" (150mm). After placement of the rock, backfill and compact any over excavated soil to ditch grade. This work shall be subsidiary to the bid item Temporary Ditch Check (Rock) (Set Price).
5. Aggregate excavated on site may be used as an alternate to the 6" rock, if approved by the Engineer.

Traffic Control

Single Lane Closure

See Sheet 30 for Single Lane Closure details. Single lane may be closed between the hours of 9:00 a.m. to 3:00 p.m.

Multiple Lane Closure

Westbound traffic on Shawnee Mission Parkway will travel using the far right lane while eastbound traffic will be merged to the far left lane, then shifted to the center lane. Left turns not to be allowed on southbound Mastin at Shawnee Mission Parkway or on eastbound Shawnee Mission Parkway at Mastin. Lanes may be closed between the hours of 9:00 p.m. on Saturday night to 9:00 a.m. Sunday Morning. Lane closures must be coordinated with the Merriam Police Department.

KANSAS DEPARTMENT OF TRANSPORTATION

CONSTRUCTION SEQUENCING
AND TRAFFIC CONTROL PLAN
MULTIPLE LANE CLOSURE
SHEET 2 OF 2

STATE	PROJECT NO.	YEAR	SHEET NO.	TOTAL SHEETS
KANSAS	46 N-0425-01	2010	24	33

1. MUTCD COMPLIANCE:

ALL TEMPORARY TRAFFIC CONTROL DEVICES AND THEIR INSTALLATION AND MAINTENANCE SHALL COMPLY WITH THE LATEST EDITION OF THE MANUAL ON UNIFORM TRAFFIC CONTROL DEVICES (MUTCD) FOR STREETS AND HIGHWAYS WHICH HAS BEEN ADOPTED BY THE SECRETARY OF TRANSPORTATION. WHENEVER THE TEMPORARY TRAFFIC CONTROL STANDARDS CONFLICT WITH THE MUTCD, THE STANDARDS SHALL GOVERN.

2. DESIGN SPEED:

THOSE ITEMS DELEGATED TO TEMPORARY TRAFFIC CONTROL SHOULD BE DESIGNED AND INSTALLED USING THE POSTED/LEGAL SPEED OF THE ROADWAY PRIOR TO WORK STARTING.

3. CLEAR ZONE:

ALL CONSTRUCTION EQUIPMENT (INCLUDING VEHICLES), MATERIALS, AND DEBRIS SHALL BE STORED OUT OF THE CLEAR ZONE. WHERE THIS CANNOT BE ACHIEVED, THE CONTRACTOR SHALL PLACE APPROPRIATE SIGNS, OBJECT IDENTIFIERS, AND/OR BARRICADES AS DESIGNATED BY THE ENGINEER. TEMPORARY TRAFFIC CONTROL DEVICES NEEDED FOR THIS CONDITION SHALL BE CONSIDERED SUBSIDIARY TO OTHER BID ITEMS.

4. MINIMUM LANE WIDTHS:

LANE WIDTHS SHALL BE A MINIMUM OF 11' (MEASURED BETWEEN CENTERLINES OF PAVEMENT MARKINGS) OR AS SHOWN ON THE PLANS, OR AS DIRECTED BY THE ENGINEER. A LANE WIDTH LESS THAN 11' MAY REQUIRE RESTRICTED ROADWAY WIDTH SIGNING.

5. FLAGGER:

A MINIMUM OF ONE FLAGGER SHALL BE STATIONED WITHIN EACH MULTI-LANE ROADWAY ACTIVITY AREA WHERE WORK IS IN A CLOSED LANE ADJACENT TO TRAFFIC AND NOT SEPARATED BY A CONCRETE SAFETY BARRIER SYSTEM.

6. PAVEMENT MARKING:

WHEN THE WORK WILL OCCUPY A LOCATION MORE THAN THREE DAYS, ALL CONFLICTING PAVEMENT MARKINGS SHALL BE REMOVED OR MASKED AND ALL TRANSITION TAPERS, CROSSOVERS, AND EDGE LINES ALONG CHANNELIZING DEVICES SHALL BE MARKED WITH SOLID 4" WIDE PAVEMENT MARKING.

7. FIRST MODULE OF IBS:

THE FIRST MODULE OF EACH INERTIAL BARRIER SYSTEM (IBS) SHALL HAVE A MINIMUM OF 2 SQ. FT. OF FLUORESCENT ORANGE ASTM TYPE IV SHEETING FACING TRAFFIC. EITHER A VERTICAL RECTANGLE OR DIAMOND SHAPE MAY BE USED.

8. PEDESTRIAN / BICYCLE SAFETY:

WORK ZONE SIGNS SHALL NOT INHIBIT PEDESTRIAN AND BICYCLE TRAFFIC ON SIDEWALKS OR OTHER AREAS DESIGNATED FOR PEDESTRIAN OR BICYCLE USE.

CONSIDERATION SHOULD BE MADE TO SEPARATE PEDESTRIAN AND BICYCLE MOVEMENTS FROM BOTH WORK SITE ACTIVITY AND VEHICULAR TRAFFIC. UNLESS A REASONABLE SAFE ROUTE THAT DOES NOT INVOLVE CROSSING THE ROADWAY CAN BE PROVIDED, PEDESTRIANS AND BICYCLISTS SHOULD BE APPROPRIATELY DIRECTED WITH ADVANCE SIGNING THAT ENCOURAGES THEM TO CROSS TO THE OPPOSITE SIDE OF THE ROADWAY. IN URBAN AND SUBURBAN AREAS WITH HIGH VEHICULAR TRAFFIC VOLUMES, THESE SIGNS SHOULD BE PLACED AT INTERSECTIONS (RATHER THAN MIDBLOCK LOCATIONS) SO THAT PEDESTRIANS AND BICYCLISTS ARE NOT CONFRONTED WITH MIDBLOCK WORK SITES THAT WILL INDUCE THEM TO ATTEMPT SKIRTING THE WORK SITE OR MAKING A MIDBLOCK CROSSING.

WHEN EXISTING PEDESTRIAN FACILITIES ARE DISRUPTED, CLOSED, OR RELOCATED, THE TEMPORARY FACILITIES SHALL BE DETECTABLE AND INCLUDE ACCESSIBILITY FEATURES CONSISTENT WITH THE FEATURES PRESENT IN THE EXISTING PEDESTRIAN FACILITY.

9. CHANGED STOP CONDITIONS:

ATTACH TWO FLAGS AND A RED TYPE "B" HIGH INTENSITY WARNING LIGHT TO ANY STOP SIGN THAT CREATES A NEW STOP CONDITION OR MOVES THE STOP CONDITION TO A NEW LOCATION. LEAVE FLAGS AND LIGHTS IN PLACE FOR AT LEAST THE FIRST 30 DAYS. INSTALL W3-1 (SYMBOLIC STOP AHEAD) SIGN IN ADVANCE OF STOP SIGN IF STOP SIGN IS NOT VISIBLE FOR A MINIMUM OF DISTANCE 'A' (SEE CHART ON TE710) OR IF STOP CONDITION IS MOVED TO LESS THAN DISTANCE 'A' FROM AN EXISTING STOP AHEAD SIGN.

10. LUMP SUM BIDDING:

WHEN TRAFFIC CONTROL IS BID LUMP SUM, ADDITIONAL DEVICES WILL BE PAID FOR AS EXTRA WORK.

11. NIGHTTIME LIGHTING:

WHEN NIGHTTIME WORK IS REQUIRED, FLOODLIGHTS SHOULD BE USED TO ILLUMINATE FLAGGER STATIONS, EQUIPMENT CROSSINGS, AND OTHER AREAS WHERE EXISTING LIGHTING IS NOT ADEQUATE FOR THE WORK TO BE PERFORMED SAFELY.

IN NO CASE SHALL FLOODLIGHTS BE PERMITTED TO CREATE A DISABLING GLARE FOR THE DRIVER. THE ADEQUACY OF THE FLOODLIGHT PLACEMENT AND ELIMINATION OF POTENTIAL GLARE SHOULD BE CHECKED BY DRIVING THROUGH THE PROJECT.

12. NCHRP REPORT 350 CRASHWORTHY REQUIREMENTS:

TRAFFIC CONTROL DEVICES SHALL MEET THE EVALUATION CRITERIA IN NCHRP REPORT 350 AS SUPPLEMENTED BY FHWA MEMORANDUM "IDENTIFYING ACCEPTABLE HIGHWAY SAFETY FEATURES," DATED JULY 25, 1997. AVAILABLE ON THE INTERNET AT http://safety.fhwa.dot.gov/roadway_dept/road_hardware/nchrp_350.htm

ANY DEVICE NOT ADDRESSED BY THE TE STANDARDS MAY BE APPROVED ON A CASE BY CASE BASIS BY THE ENGINEER. THE DEVICE SHALL BE ACCOMPANIED BY AND INSTALLED ACCORDING TO NCHRP REPORT 350.

THE CONTRACTOR SHALL:

1) PROVIDE TO THE ENGINEER A COPY OF THE MANUFACTURER'S SELF-CERTIFICATION THAT ANY CATEGORY 1 (i.e. - PLASTIC CONICAL DELINEATORS, TUBULAR MARKERS, DRUMS WITHOUT ATTACHMENTS) AND CATEGORY 2 (i.e. - PORTABLE SIGN STANDS (WITH SIGNS), TYPE II AND III BARRICADES, AND VERTICAL PANELS) DEVICES USED ON THE PROJECT ARE NCHRP REPORT 350 COMPLIANT.

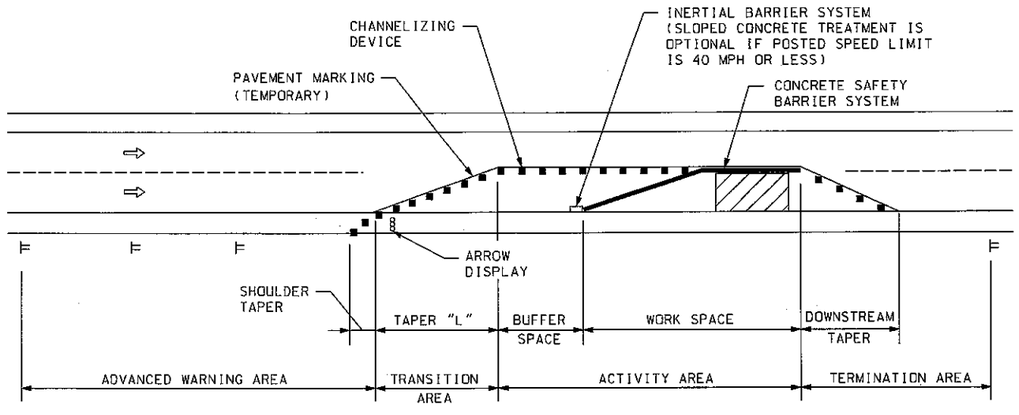
2) PROVIDE TO THE ENGINEER A COPY OF THE ENTIRE FHWA NCHRP REPORT 350 ACCEPTANCE LETTER (WZ-xxx) FOR ANY CATEGORY 2 DEVICE (i.e. - PORTABLE SIGN STANDS (WITH SIGNS), TYPE II AND III BARRICADES, AND VERTICAL PANELS) USED ON THE PROJECT. WORK ZONE FHWA NCHRP REPORT 350 ACCEPTANCE LETTERS (WZ-xxx) ARE AVAILABLE ON THE INTERNET AT:
http://safety.fhwa.dot.gov/roadway_dept/road_hardware/listing.cfm?code=workzone

3) CERTIFY THAT THE TRUCK MOUNTED ATTENUATORS (TMA'S) (WHICH ARE DEFINED AS CATEGORY 3 DEVICES BY THE FHWA MEMORANDUM) WERE PURCHASED PRIOR TO OCTOBER 1, 1998, AND INCLUDE A COPY OF THE ENTIRE FHWA ACCEPTANCE LETTER STATING THAT THE TMA'S ARE NCHRP REPORT 230 COMPLIANT; OR IF THE DEVICES WERE PURCHASED AFTER OCTOBER 1, 1998, INCLUDE A COPY OF THE ENTIRE FHWA'S ACCEPTANCE LETTER STATING THAT THE TMA'S ARE NCHRP REPORT 350 COMPLIANT.

ALL CATEGORY 1 & 2 DEVICES SHALL BE NCHRP REPORT 350 COMPLIANT. TMA'S, PURCHASED PRIOR TO OCTOBER 1, 1998, MAY BE USED UNTIL THE END OF THEIR SERVICEABLE LIVES.

13. TYPE "A" LOW INTENSITY WARNING LIGHTS:

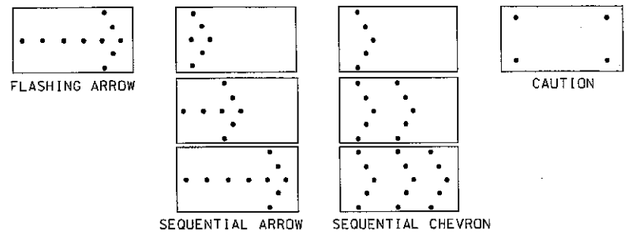
A TYPE "A" LOW INTENSITY WARNING LIGHT IS AN L.E.D. BI-DIRECTIONAL FLASHING WORK ZONE WARNING LIGHT.



TYPICAL WORK ZONE COMPONENTS

NOTE:
REFER TO STD. TE702 FOR TAPER "L" FORMULA.

ARROW DISPLAYS



ARROW DISPLAY ELEMENTS SHALL BE CAPABLE OF A MINIMUM 50 PERCENT DIMMING FROM THEIR FULL-RATED LAMP VOLTAGE. FULL LAMP VOLTAGE SHOULD BE USED DURING THE DAY AND DIMMED MODE SHALL BE USED AT NIGHT. FOR SHOULDER WORK, ROADSIDE WORK NEAR THE SHOULDER, BLOCKING THE SHOULDER, OR FOR TEMPORARY CLOSING ONE LANE ON A TWO-LANE, TWO-WAY ROADWAY, AN ARROW PANEL SHALL BE USED ONLY IN THE CAUTION MODE.

BUFFER SPACE

SPEED (MPH) *	20	25	30	35	40	45	50	55	60	65	70
LENGTH (ft)	115	155	200	250	305	360	425	495	570	645	730

NEITHER WORK ACTIVITY NOR STORAGE OF EQUIPMENT, VEHICLES, OR MATERIAL SHOULD OCCUR IN THE BUFFER SPACE. WHEN A PROTECTION VEHICLE IS PLACED IN ADVANCE OF THE WORK SPACE, ONLY THE SPACE UPSTREAM OF THE VEHICLE CONSTITUTES THE BUFFER SPACE.

* POSTED SPEED PRIOR TO WORK STARTING

IF TEMPORARY CONCRETE SAFETY BARRIER SYSTEM IS USED TO SEPARATE APPROACHING TRAFFIC FROM THE WORK SPACE, THE BARRIER SYSTEM SHALL BE CONSIDERED PART OF THE ACTIVITY AREA. A FULL LANE WIDTH SHOULD BE AVAILABLE THROUGHOUT THE LENGTH OF THE BUFFER SPACE. SEE TYPICAL WORK ZONE COMPONENTS.

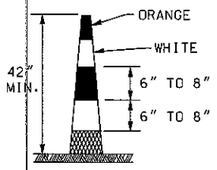
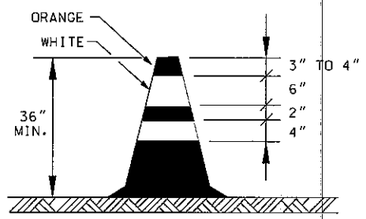
DRUM



CONICAL DELINEATOR

DRUMS AND CONICAL DELINEATORS SHALL HAVE AT LEAST TWO ORANGE AND TWO WHITE 6" TO 8" WIDE RETROREFLECTIVE STRIPES. ADDITIONAL STRIPES MAY BE NON-RETROREFLECTIVE. IF THERE ARE NON-RETROREFLECTIVE SPACES BETWEEN ADJACENT STRIPES, THEY SHALL BE NO MORE THAN 3" WIDE.

ALL RETROREFLECTIVE STRIPES ON DRUMS SHALL BE ASTM TYPE III SHEETING. THE WHITE STRIPES ON CONICAL DELINEATORS SHALL BE ASTM TYPE III SHEETING. ORANGE STRIPES ON ALL CONICAL DELINEATORS SHALL BE FLUORESCENT ORANGE ASTM TYPE IV SHEETING.



TRAFFIC CONE

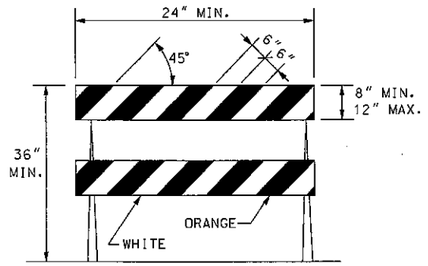
TRAFFIC CONES MAY BE USED AS CHANNELIZING DEVICES FOR DAYTIME OPERATIONS ONLY. THEY WILL NOT BE PAID FOR SEPARATELY, BUT WILL BE SUBSIDIARY TO OTHER TRAFFIC CONTROL BID ITEMS. THE ENGINEER MAY REQUIRE THAT TRAFFIC CONES BE SUPPLEMENTED BY OTHER TRAFFIC CONTROL DEVICES IN CERTAIN SITUATIONS.

ITEM \ LOCATION		CROSS-OVERS	SHOOFLY DIVERSIONS	TANGENTS	TAPERS	RAMPS	HEAD TO HEAD	OBJECT IDENTIFIER	
PORTABLE									
	DRUMS	YES	YES	YES	YES	YES	(1)	YES	
	CONICAL DELINEATORS	YES	YES	YES	YES	YES	(1)	YES	
	VERTICAL PANELS	(2)	(2)	(2)	(2)	(2)	(1,2)	YES	
	DIRECTION INDICATOR BARRICADE	NO	NO	NO	YES	NO	NO	NO	
	TYPE II BARRICADE	(2)	(2)	(2)	(2)	NO	NO	YES	
FIXED									
	TUBULAR MARKERS	(3)	(3)	(3)	NO	(3)	YES	NO	
	VERTICAL PANELS	(3)	(3)	(3)	(3)	(3)	(3)	YES	

(1) Not allowed on centerline delineation along freeways or expressways.

(2) The stripes shall slope downward to the traffic side for channelization.

(3) May be used upon the approval of the Engineer.

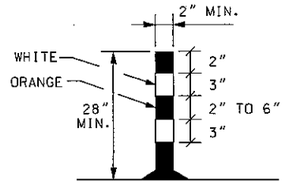


TYPE II BARRICADE

FOR RAILS LESS THAN 36" LONG, 4" WIDE STRIPES MAY BE USED.

THE ENTIRE AREA OF BARRICADE RAILS, BOTH FRONT AND BACK, SHALL BE ASTM TYPE III SHEETING.

THE STRIPES SHALL SLOPE DOWNWARD TO THE TRAFFIC SIDE FOR CHANNELIZATION.



TUBULAR MARKER

THE TWO WHITE RETROREFLECTIVE STRIPES SHALL BE ASTM TYPE III SHEETING.

TAPER FORMULAS:

L = WS FOR SPEEDS OF 45 MPH OR MORE

$L = WS^2/60$ FOR SPEEDS OF 40 MPH OR LESS

WHERE: L = MINIMUM LENGTH OF TAPER IN FEET
S = NUMERICAL VALUE OF POSTED SPEED PRIOR TO WORK STARTING IN MPH
W = WIDTH OF OFFSET IN FEET

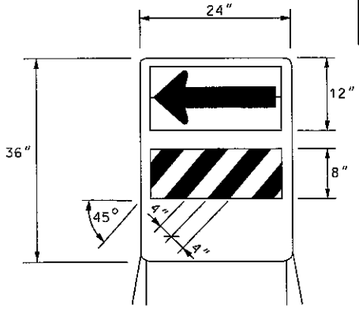
CHANNELIZER PLACEMENT:

(A) THE SPACING BETWEEN DEVICES IN TRANSITION AREA (TAPER) SHOULD NOT EXCEED A DISTANCE IN FEET EQUAL TO 1/2 THE POSTED SPEED LIMIT IN MPH PRIOR TO WORK STARTING.

(B) THE SPACING BETWEEN DEVICES IN THE ADVANCED WARNING AREA AND THE ACTIVITY AREA SHOULD NOT EXCEED A DISTANCE IN FEET EQUAL TO TWO TIMES THE POSTED SPEED LIMIT IN MPH PRIOR TO WORK STARTING.

(C) CHANNELIZING DEVICES SHALL BE PLACED FOR OPTIMUM VISABILITY, NORMALLY AT RIGHT ANGLES TO THE TRAFFIC FLOW.

(D) CHANNELIZING DEVICES PLACED ALONG SHOULDER EDGES OR IN DROPOFFS SHALL HAVE A MINIMUM OF 24" FROM THE TOP OF THE CHANNELIZING DEVICE TO THE TOP OF THE PAVEMENT.

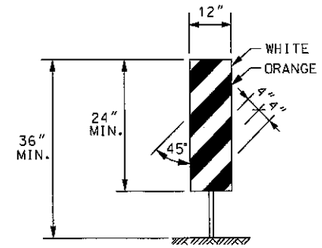


DIRECTION INDICATOR BARRICADE

THE ARROW PANEL SHALL BE BLACK ON FLUORESCENT ORANGE ASTM TYPE IV SHEETING. THE STRIPES SHALL BE ORANGE AND WHITE ASTM TYPE III SHEETING SLOPING DOWNWARD IN THE DIRECTION TRAFFIC IS TO PASS.

THE DIRECTION INDICATOR BARRICADE SHALL BE USED IN SERIES TO DIRECT THE MOTORIST INTO THE INTENDED LANE OF TRAVEL.

THE ARROW PANEL SHOULD NOT BE VISIBLE TO OPPOSING TRAFFIC.



VERTICAL PANEL

THE ENTIRE AREA OF VERTICAL PANELS, BOTH FRONT AND BACK, SHALL HAVE ASTM TYPE III SHEETING. THE STRIPES SHALL SLOPE DOWNWARD TO THE TRAFFIC SIDE FOR CHANNELIZATION.

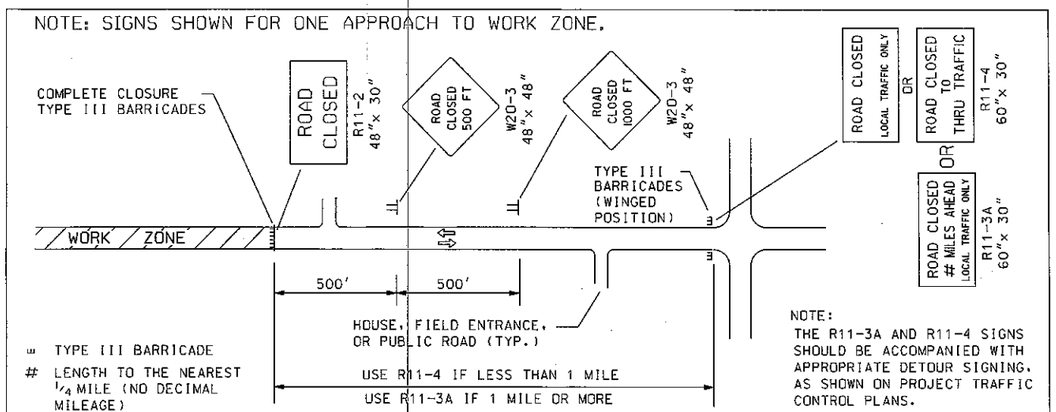

FIGURE 1: TYPICAL SIGNING FOR ROAD CLOSURE

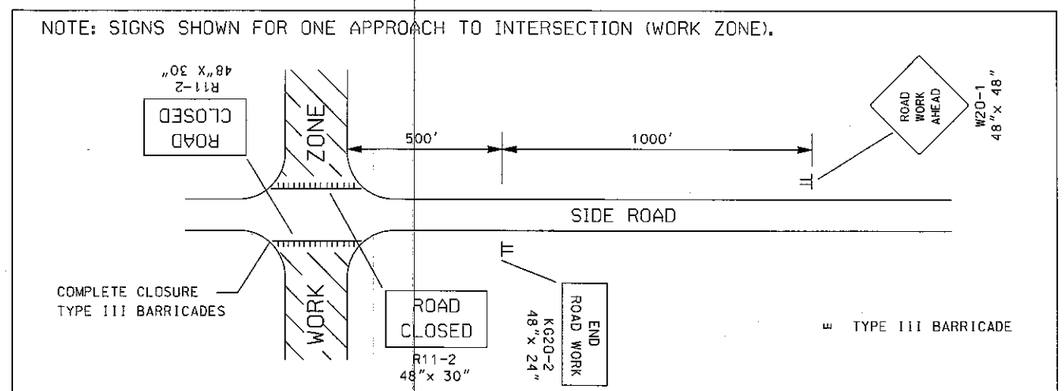

FIGURE 2: TYPICAL SIGNING FOR SIDE ROAD OPEN

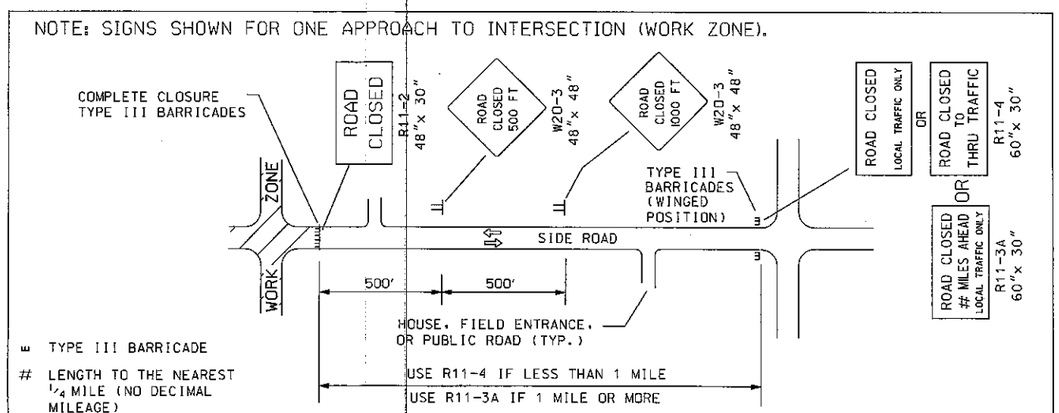

FIGURE 3: TYPICAL SIGNING FOR SIDE ROAD CLOSED

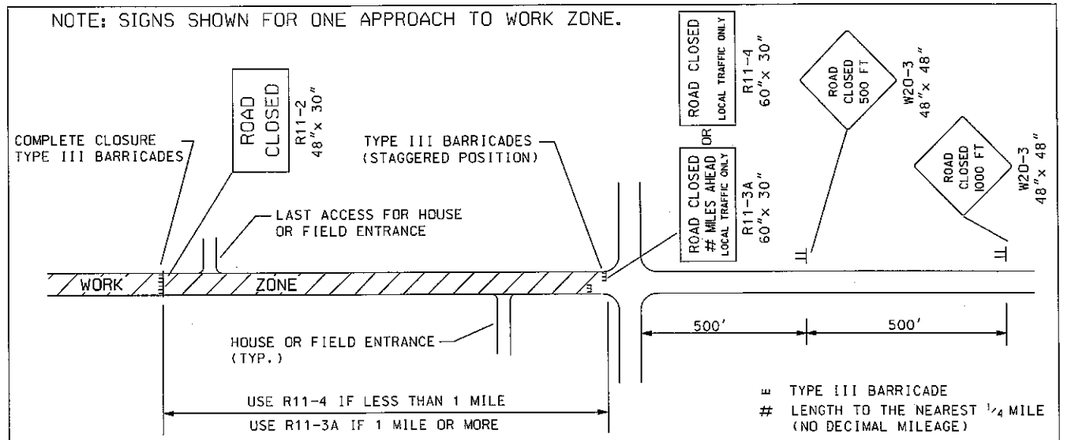

FIGURE 4: TYPICAL SIGNING FOR ROAD CLOSURE - LOCAL TRAFFIC ACCESS

NOTES:

1. SIGNS:

   THE R11-4 (ROAD CLOSED TO THRU TRAFFIC OR ROAD CLOSED LOCAL TRAFFIC ONLY) SIGN SHALL BE USED WHEN THE DISTANCE TO THE POINT OF COMPLETE CLOSURE OF THE ROADWAY IS LESS THAN 1 MILE.

   THE R11-3A (ROAD CLOSED # MILES AHEAD LOCAL TRAFFIC ONLY) SIGN SHALL BE USED WHEN THE DISTANCE TO THE POINT OF COMPLETE CLOSURE OF THE ROADWAY IS 1 MILE OR GREATER.

   THE WORDS "BRIDGE OUT" (OR BRIDGE CLOSED) MAY BE SUBSTITUTED FOR THE WORDS "ROAD CLOSED" ON THE R11-3A OR R11-4 SIGN WHERE APPLICABLE.

2. BARRICADE PLACEMENT:

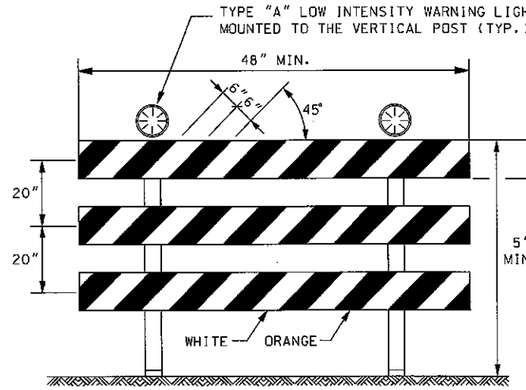
   A) COMPLETE ROAD CLOSURE

   WHEN A ROADWAY IS CLOSED, TYPE III BARRICADES SHALL BE PLACED END-TO-END TO COMPLETELY COVER THE ROADWAY AND SHOULDERS. WHEN ACCESS MUST BE ALLOWED FOR CONSTRUCTION OR OTHER OFFICIAL/GOVERNMENT VEHICLES, TYPE III BARRICADES SHALL BE LONGITUDINALLY STAGGERED FAR ENOUGH APART FROM ONE ANOTHER TO ALLOW SAFE PASSAGE OF VEHICLES AND MAINTAIN THE APPEARANCE OF A CLOSED ROADWAY. TYPE III BARRICADES SHALL BE REALIGNED AND PLACED END-TO-END TO DENY ANY ACCESS WHEN THE CONSTRUCTION ACTIVITY HAS CEASED FOR THE DAY.

   B) ROAD CLOSED - LOCAL TRAFFIC

   AS SHOWN IN FIGURE 4, WHEN LOCAL TRAFFIC MUST BE ALLOWED ACCESS INTO THE WORK ZONE, TYPE III BARRICADES SHALL BE LONGITUDINALLY STAGGERED TO MAINTAIN THE APPEARANCE OF A CLOSED ROADWAY. A SECOND LINE OF END-TO-END TYPE III BARRICADES SHALL BE PLACED JUST BEYOND THE LAST ACCESS POINT IN THE WORK ZONE, TO COMPLETELY CLOSE THE ROADWAY AS DESCRIBED IN NOTE 2-A.

   AS SHOWN IN FIGURE 1 AND FIGURE 3, AT THE POINT WHERE THRU TRAFFIC MUST DETOUR AND LOCAL TRAFFIC CAN PROCEED TO THE LOCATION WHERE THE ROADWAY IS COMPLETELY CLOSED, THE R11-3A (ROAD CLOSED # MILES AHEAD LOCAL TRAFFIC ONLY) OR R11-4 (ROAD CLOSED LOCAL TRAFFIC ONLY OR ROAD CLOSED TO THRU TRAFFIC) SIGN SHALL BE USED WITH TYPE III BARRICADES (WINGED POSITION), PLACED ON THE SHOULDERS OF ROADWAY.



TYPE III BARRICADE WITH LIGHTS

THE ENTIRE AREA OF BARRICADE RAILS, BOTH FRONT AND BACK, SHALL HAVE ASTM TYPE III SHEETING.

THE STRIPES SHALL SLOPE DOWNWARD TO THE SIDE TRAFFIC IS TO PROCEED OR TOWARD THE CENTER OF THE ROADWAY AT ROAD CLOSURES.

APPROVED SIGNS MOUNTED ON TYPE III BARRICADES SHOULD NOT COVER MORE THAN 50% OF THE TOP TWO RAILS OR 33% OF THE TOTAL AREA OF THE THREE RAILS.

WHEN BARRICADES ARE PLACED END-TO-END OR STAGGERED, A TYPE "A" LOW INTENSITY WARNING LIGHT SHALL BE MOUNTED TO THE VERTICAL POST NEAR EACH OUTSIDE CORNER OF THE END BARRICADES.

TYPE "A" LOW INTENSITY WARNING LIGHTS SHALL BE MAINTAINED SO AS TO BE VISIBLE ON A CLEAR NIGHT FROM A DISTANCE OF 3000'.

KANSAS	46 N-0425-01	2010	27	33

GENERAL NOTES

1. MAINTENANCE:

THE CONTRACTOR SHALL MAINTAIN ALL SIGNS AND DEVICES IN AN UPRIGHT POSITION. THE CONTRACTOR SHALL CLEAN OR REPLACE ANY DAMAGED OR ILLEGIBLE SIGN OR DEVICE AS DIRECTED BY THE ENGINEER.

2. EXISTING SIGNS:

IF EXISTING SIGNS THAT ARE TO REMAIN (WHETHER DENOTED ON THE PLANS OR NOT) INTERFERE WITH CONSTRUCTION WORK, THE CONTRACTOR SHALL REMOVE, STORE, AND RESET THE SIGNS. THIS SHALL BE SUBSIDIARY TO OTHER TRAFFIC CONTROL BID ITEMS. SIGNING DAMAGED BY THE CONTRACTOR SHALL BE REPLACED AT THE CONTRACTOR'S EXPENSE.

3. CONFLICTING SIGNS, SIGNS NOT IN USE, AND TRAFFIC SIGNALS:

SIGNS AND TRAFFIC SIGNALS THAT ARE IN CONFLICT WITH THE TRAFFIC CONTROL PLAN OR DO NOT APPLY TO THE TRAFFIC OPERATIONS SHALL BE IMMEDIATELY REMOVED, TURNED SO NOT VISIBLE TO TRAFFIC FROM ANY DIRECTION, OR COMPLETELY COVERED WITH ADEQUATE OPAQUE WATERPROOF MATERIAL. TAPE SHALL NOT BE APPLIED TO THE FACE OF THE SIGN.

4. PORTABLE AND POST MOUNTED SIGNS:

TEMPORARY TRAFFIC CONTROL SIGNS THAT ARE ANTICIPATED TO REMAIN IN PLACE FOR 3 DAYS OR LESS ARE CONSIDERED "PORTABLE." PORTABLE SIGNS SHALL BE MOUNTED ON AN APPROVED SUPPORT AT A MINIMUM HEIGHT OF 12" ABOVE THE TRAVELED WAY. TRAFFIC CONTROL SIGNS IN PLACE FOR OVER 3 DAYS ARE REQUIRED TO BE MOUNTED ON APPROVED POSTS. A MINIMUM OF 42" OF THE APPROVED POST MUST BE BELOW THE GROUND SURFACE WITH ADEQUATE BACKFILL AND COMPACTION. ALL POSTS AT MINIMUM SHALL EXTEND TO THE TOP EDGE OF THE SIGN AND NO GREATER THAN 6" ABOVE THE SIGN.

WHEN THE SIGN WIDTH IS EQUAL TO OR GREATER THAN 9', THREE OR MORE WOOD POSTS MAY BE USED WITH A MINIMUM OF 4' BETWEEN THE CENTERLINE OF EACH POST. ALL SIGNS LESS THAN 9' IN WIDTH SHALL USE A MAXIMUM OF TWO WOOD POSTS.

"ROLL-UP" SIGNS MAY BE USED FOR PORTABLE WARNING SIGNS. THEY MUST BE FLUORESCENT ORANGE ASTM TYPE IV SIGNS OF OPAQUE MATERIAL. MESH SIGNS ARE NOT ALLOWED.

5. SHEETING:

ALL ORANGE SIGNS SHALL HAVE FLUORESCENT ORANGE ASTM TYPE IV SHEETING. ALL OTHER SIGNS SHALL HAVE ASTM TYPE III SHEETING OF STANDARD COLORS.

6. SIGNS INVOLVING SPEEDS:

THE W3-5 (SPEED REDUCTION) SHOULD BE USED ONLY IF THE ENGINEER DETERMINES THAT A REDUCED SPEED IS REQUIRED ON THE PROJECT.

THE KM4-20 (WORK ZONE) PLAQUE SHALL BE PLACED ABOVE ALL SPEED LIMIT SIGNS, (R2-1), EXISTING AND TEMPORARY. MOUNT THE WORK ZONE PLAQUES TO THE POST. DO NOT OVERLAP THE R2-1 AND KM4-20 SIGNS.

FOR SPEEDS OF 30 MPH OR LESS, THE W1-1(TURN) OR W1-3(REVERSE TURN) SHOULD BE USED. FOR SPEEDS OF 35 MPH OR MORE, THE W1-2(CURVE) OR W1-4(REVERSE CURVE) SHOULD BE USED. THE W13-1(MPH) IS TO BE ELIMINATED IF THE ADVISORY SPEED IS WITHIN 5 MPH OF THE SPEED LIMIT.

7. SIGNS CONTROLLING WORK ZONE:

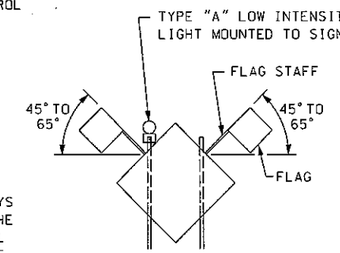
THE KG20-2(END ROAD WORK) SHOULD BE PLACED 500' FROM THE END OF THE ACTUAL WORK SPACE, NOT NECESSARILY AT THE EXTREME LIMITS OF THE PROJECT. THE KG20-2 SHOULD BE MOUNTED ON TWO POSTS. THE KG20-2 MAY BE MOUNTED ON ONE POST IF IN URBAN AREAS WHERE UTILITIES ARE A PROBLEM AND WIND LOADS ARE NOT AN ISSUE.

WHERE TWO WORK ZONES ARE LESS THAN 1 MILE APART IN RURAL AREAS OR 1/4 MILE APART IN URBAN AREAS, THE KG20-2(END ROAD WORK) FOR THE FIRST WORK ZONE AND THE W20-1(ROAD WORK) FOR THE SECOND WORK ZONE SHOULD BE ELIMINATED.

8. WARNING LIGHTS ON SIGNS:

TYPE "A" LOW INTENSITY WARNING LIGHTS SHOULD BE USED WITH ALL CONSTRUCTION ACTION WARNING SIGNS AND SHALL NOT BE USED ON SIGNS MOUNTED LESS THAN 5' HIGH ON TEMPORARY SUPPORTS. ON ALL OTHER CONSTRUCTION WARNING SIGNS, TYPE "A" LOW INTENSITY WARNING LIGHTS ARE TO BE USED AS DIRECTED BY THE ENGINEER.

TYPE "A" LOW INTENSITY WARNING LIGHTS SHALL BE MAINTAINED SO AS TO BE CAPABLE OF BEING VISIBLE ON A CLEAR NIGHT FROM A DISTANCE OF 3000 FT. IF A TYPE "A" LOW INTENSITY WARNING LIGHT HAS A SEPARATE BATTERY CASE, THE BATTERY CASE SHALL BE MOUNTED NO HIGHER THAN 12" ABOVE THE GROUND AND MOUNTED BEHIND THE SIGN POST. A TYPE "A" LOW INTENSITY WARNING LIGHT WHERE THE LENS AND BATTERY ARE ONE UNIT SHALL BE MOUNTED ON THE TEMPORARY SIGN POST NEAREST TO THE TRAVELED WAY. FLAGS SHALL NOT INTERFERE WITH THE VISABILITY OF THE TYPE "A" LOW INTENSITY WARNING LIGHT.



TWO (2) 18" x 18" FLUORESCENT RED-ORANGE FLAGS SHALL BE ATTACHED (IN THE POSITION SHOWN) ON THE W20-2(DETOUR), W1-1(TURN), W1-2(CURVE), W1-3(REVERSE TURN), W1-4(REVERSE CURVE), W3-3(SIGNAL AHEAD), W4-2(LANE REDUCTION), W20-4(ONE LANE ROAD), W20-5(LANE CLOSED), W20-7A(FLAGGER), AND W3-4 (BE PREPARED TO STOP) SIGNS AND ANY OTHER ACTION SIGNS AS SHOWN ON THE PLANS OR DIRECTED BY THE ENGINEER. THE FLAGS AND STAFFS ARE TO BE ATTACHED IN SUCH A MANNER THAT THE SIGN WILL NOT BE OBSCURED. THE FLAGS MAY BE EITHER A CLOTH OR VINYL MATERIAL. THE FLAGS SHALL BE SUBSIDIARY TO THE CONSTRUCTION SIGN BID ITEMS.

9. AFAD'S

FLAGGER SHALL BE A PERSON WHO PROVIDES TEMPORARY TRAFFIC CONTROL.

FLAGGER STATIONS SHALL BE LOCATED SUCH THAT APPROACHING ROAD USERS WILL HAVE SUFFICIENT DISTANCE TO STOP AT AN INTENDED STOPPING POINT.

THE FIVE CATEGORIES OF WORK DURATION AND THEIR TIME AT A LOCATION SHALL BE:

A. LONG-TERM STATIONARY IS WORK THAT OCCUPIES A LOCATION FOR MORE THAN 3 DAYS.
B. INTERMEDIATE-TERM STATIONARY IS WORK THAT OCCUPIES A LOCATION MORE THAN ONE DAYLIGHT PERIOD UP TO 3 DAYS, OR NIGHTTIME WORK LASTING LONGER THAN 1HOUR.
C. SHORT-TERM STATIONARY IS DAYTIME WORK THAT OCCUPIES A LOCATION FOR MORE THAN 1HOUR WITHIN A SINGLE DAYLIGHT PERIOD.
D. SHORT DURATION IS WORK THAT OCCUPIES A LOCATION UP TO 1HOUR.
E. MOBILE IS WORK THAT MOVES INTERMITTENTLY OR CONTINUOUSLY.

ONE LANE, TWO-WAY VEHICULAR TRAFFIC FLOW REQUIRES AN ALL-RED INTERVAL OF SUFFICIENT DURATION FOR ROAD USERS TO CLEAR THE PORTION OF THE TEMPORARY TRAFFIC CONTROL ZONE CONTROLLED BY THE TRAFFIC CONTROL SIGNALS. SAFEGUARDS SHALL BE INCORPORATED TO AVOID THE POSSIBILITY OF CONFLICTING SIGNAL INDICATIONS AT EACH END OF THE TEMPORARY TRAFFIC CONTROL ZONE.

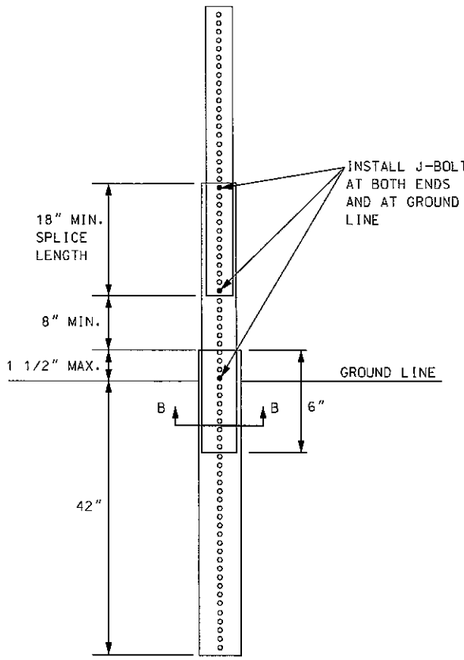
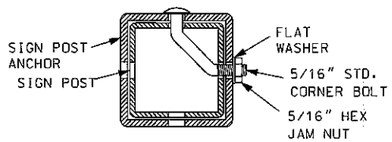
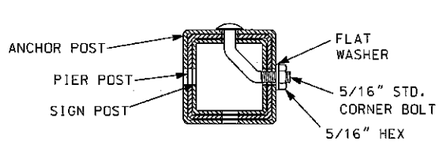
P.S.S.T. DETAIL



TELESCOPING P.S.S.T. DETAIL



SECTION A-A



SECTION B-B

DETAILS FOR 2", 2 1/4", OR 2 1/2" SIGN POST

NOTE:

SIGN POSTS, POST ANCHORS, AND POST ANCHOR SLEEVES:

THE SIGN POSTS, POST ANCHORS, AND POST ANCHOR SLEEVES SHALL CONFORM TO (1) HOT ROLLED CARBON STEEL ASTM A-570 GRADE 33 OR ASTM STRUCTURAL QUALITY C 1021 WITH A HOT-DIPPED GALVANIZING CONFORMING TO ASHTO M-120 WITH AN INLINE SYSTEM FOLLOWED BY A CHROMATE CONVERSION AND A CROSS-LINKED POLYURETHANE ACRYLIC EXTERIOR COATING OR (2) A GALVANIZED FINISH COLD ROLLED CARBON STEEL ASTM A-446 GRADE A WITH A GALVANIZING CONFORMING TO ASTM A 525, DESIGNATION G-90.

THE SIGN POST SHALL HAVE 7 /16" DIA. HOLES OR 7 /16" DIA. EMBOSSED RING (DIE-CUT KNOCKOUTS) AT 1" CENTERS ON ALL FOUR SIDES FOR THE TOTAL LENGTH OF THE POST. THE CORNER BOLTS, NUTS, AND WASHERS SHALL BE BID SUBSIDIARY.

ALL HOLES SHALL BE DRILLED OR PUNCHED AND ALL WELDS, CUTS, BURRS, AND SHARP EDGES ARE TO BE SMOOTHED OFF BEFORE APPLICATION OF FINISH.

BASIS OF ACCEPTANCE:

ACCEPTING OF THE STEEL POSTS, ANCHORS, SLEEVES, AND FASTENERS FURNISHED TO COMPLY WITH THE ABOVE REQUIREMENTS WILL BE BASED ON RECEIPT AND APPROVAL OF A TYPE D CERTIFICATION AS DESCRIBED IN SECTION 2600 OF THE STANDARD SPECIFICATIONS FOR STATE ROAD AND BRIDGE CONSTRUCTION (2007) AMD VISUAL INSPECTION FOR CONDITION AND DIMENSIONAL REQUIREMENTS.

RECOM. FOR APPROVAL-DATE 9-13-13

LOCAL PUBLIC OFFICIAL

KANSAS DEPARTMENT OF TRANSPORTATION

GENERAL NOTE

THE GEOLOGICAL INFORMATION SHOWN ON THESE PLANS IS FROM STUDIES MADE IN THE FIELD AND REPRESENTS THE BEST INFORMATION AVAILABLE TO THE KANSAS DEPARTMENT OF TRANSPORTATION.

AT BORROW AREA LOCATIONS ADJACENT TO THE RIGHT OF WAY, UTILITY POLES MAY BE SET AT THE PERMANENT LOCATIONS PRIOR TO CONSTRUCTION AS APPROVED BY THE ENGINEER PROVIDED A MINIMUM VERTICAL CLEARANCE, IN ACCORDANCE WITH THE NATIONAL ELECTRICAL SAFETY CODE, IS OBTAINED. THE CONTRACTOR WILL BE REQUIRED TO WORK AROUND THESE POLES TO COMPLETE THE WORK.

ALL BORROW TO BE OBTAINED FROM AREAS PROVIDED BY THE CONTRACTOR SHALL BE APPROVED BY THE ENGINEER, BOTH AS TO SUITABILITY OF MATERIAL AND SITE LOCATION. LOCATIONS WHICH, IN THE OPINION OF THE ENGINEER, CONTAIN UNSUITABLE MATERIAL OR WILL LEAVE AN UNSIGHTLY APPEARANCE ON THE PROJECT WILL NOT BE APPROVED.

CHANNELS SHALL BE CUT AT BOX CULVERTS (UNLESS OTHERWISE NOTED) TO FLOW LINE ELEVATIONS AND TO A WIDTH OF ONE FOOT OUTSIDE OF EACH OUTSIDE WALL AND WITH SLOPES 2 TO 1 PRIOR TO CONSTRUCTION OF THE CULVERT.

EMBANKMENT QUANTITIES FOR INITIAL CONSOLIDATION AND SETTLEMENT SHOWN IN THE EARTHWORK QUANTITIES ARE SUBSIDIARY TO OTHER EARTHWORK ITEMS. MATERIAL FOR THE EMBANKMENT IS INCLUDED IN THE EXCAVATION QUANTITIES.

EXCAVATION REQUIRED FOR PLACING SELECT SOIL IS INCLUDED IN THE COMMON EXCAVATION QUANTITIES.

WHERE EASEMENTS ARE SHOWN ON RAILROAD RIGHT OF WAY, THE CONTRACTOR SHALL BE REQUIRED TO WORK AROUND AND NOT DISTURB THE RAILROAD COMMUNICATION OR SIGNAL POLES OR LINES.

EXCAVATION SHOWN TO BE WASTED SHALL BE WASTED ON SITES PROVIDED BY THE CONTRACTOR. THESE SITES SHALL BE APPROVED BY THE ENGINEER AS TO SUITABILITY, APPEARANCE, AND SITE LOCATION. LOCATIONS THAT, IN THE OPINION OF THE ENGINEER, WILL LEAVE AN UNSIGHTLY APPEARANCE WILL NOT BE APPROVED.

ALL TREES, HEDGE ROWS, SHELTERBELTS, AND WOODY SHRUBS NOT SHOWN TO BE REMOVED AND LOCATED BETWEEN THE CONSTRUCTION LIMITS AND THE RIGHT-OF-WAY LINE OR EASEMENT LINE SHALL BE SPARED UNLESS DIRECTED BY THE ENGINEER TO BE REMOVED. ALL TREES WINTHIN THE APPROPRIATE CLEAR ZONE SHALL BE REMOVED.

ALL SAW CUTS SHALL BE FULL DEPTH AND SHALL NOT BE PAID FOR DIRECTLY, BUT SHALL BE CONSIDERED SUBSIDIARY TO OTHER ITEMS IN THE CONTRACT.

CONSTRUCTION ACTIVITIES WILL NOT IMPACT THE STREAM BED OF TURKEY CREEK. FORMWORK, EQUIPMENT, TEMPORARY SHORING, COFFERDAMS, ARE NOT ALLOWED WITHIN THE STREAM BED.

THE CITY OF MERRIAM WILL REMOVE THE DECORATIVE STREET LIGHTS LOCATED ON EACH CORNER OF THE EXISTING BRIDGE PRIOR TO CONSTRUCTION. NEW STREET LIGHT POLES AND LUMINARES WILL BE PROVIDED AND INSTALLED BY THE CITY OF MERRIAM AFTER COMPLETION OF THE PROJECT. THE CONTRACTOR WILL INSTALL ALL CONDUITS, WIRE, AND FOOTINGS. SEE BRIDGE AND AESTHETIC TREATMENT PLANS.

TEMPORARY EROSION CONTROL SHALL BE PLACED ACCORDING TO KDOT STANDARD SPECIFICATIONS. CURB INLET PROTECTION SHALL BE PLACED AT THE FIRST CURB INLET LOCATION UPSTREAM AND DOWNSTREAM OF THE PROJECT LIMITS. CURB INLET PROTECTION WILL BE PLACED ALONG THE PEDESTRIAN TRAIL UNDERNEATH THE BRIDGE, ALONG EXCAVATION AREAS ON ABUTMENT 2, AND RETAINING WALL LOCATIONS.

THE CONTRACTOR SHALL CONTACT DAN MILLER AT THE CITY OF OVERLAND PARK KANSAS AND PROVIDE A MINIMUM OF SEVEN (7) DAYS NOTICE SO THAT THE CITY CAN REMOVE THE STORM WATER MONITORING SYSTEM LOCATED AT THE SOUTHEAST CORNER OF THE BRIDGE.

THE CONTRACTOR SHALL RE-ESTABLISH THE JOHNSON COUNTY BENCHMARK #825 LOCATED ON THE SOUTHEAST CORNER OF THE EXISTING BRIDGE OVER TURKEY CREEK ACCORDING TO THE REQUIREMENTS AND SPECIFICATIONS OF JOHNSON COUNTY PUBLIC WORKS. ALL WORK AND MATERIALS REQUIRED TO RE-ESTABLISH THE BENCHMARK SHALL BE INCLUDED UNDER THE BID ITEM "CONTRACTOR CONSTRUCTION STAKING (LUMP SUM)". SEE THE KDOT STANDARD SPECIFICATIONS FOR DETAILS.

THE CONTRACTOR SHALL CONTACT KCP&L A MINIMUM OF 3 DAYS PRIOR TO ANY OVERHEAD WORK BEING PERFORMED (I.E. STEEL GIRDER PLACMENT) TO ALLOW KCP&L TO PROVIDE AN ON-SITE REPRESENTATIVE WHILE THE WORK IS BEING PERFORMED.

ALL CONCRETE CONSTRUCTION SHALL BE "KCMMB 4K".

THE CONTRACTOR SHALL CONTACT THE CITY OF MERRIAM TO FINALIZE THE SOD PLACEMENT LIMITS FOR THE PROJECT. LANDSCAPING PLANTINGS AT THE CORNERS OF THE BRIDGE WILL BE PROVIDED AND INSTALLED BY THE CITY OF MERRIAM.

GENERAL NOTE

Combined curb and gutter or gutter adjoining concrete pavement may, at the contractor's option, be constructed either monolithically or separately, using KCMMB 4K. The combined curb and gutter or gutter shall have the same section as shown on the plans. If constructed monolithically, the longitudinal joint and tie bars shall be omitted from the combined curb and gutter or gutter. Pavement joints shall be continued through curb or gutter and no other planes of weakness will be required. Joints in the combined curb and gutter or gutter are to be filled with the same material as used for the pavement joints.
Expansion joints in the combined curb and gutter are to be placed opposite expansion joints in the pavement.
Where combined curb and gutter or gutter does not abut concrete pavement or concrete base course, omit tie bars and place a 1" Preformed Expansion Joint Filler (Type B) cut to the dimensions of the combined curb and gutter or gutter, at a spacing not to exceed 250' and at the ends of curb returns. Planes of weakness shall be constructed at 10'-0" intervals.
A 4' length of transition from normal gutter section to the tapered gutter section shall be used at the ends of each run of gutter except where the gutter abuts a curb, such as at the end of a bridge. Inlets shall be located so as not to fall within this transition section.
Where pressure relief joint is placed across the pavement, and gutter or curb and gutter is continued on for more than 10', use 4"x4" membrane sealant installed with bonding adhesive through gutter section, shaped to fit gutter or curb and gutter. See Std. Drawing RD712.
For expansion joint treatment where combined curb and gutter or gutter abuts a bridge wing on a U-type abutment see bridge drawings.
Longitudinal joints shall be sawed and sealed with joint sealant, see Standard Specifications.

Y If constructed monolithically, the longitudinal joint is not required.

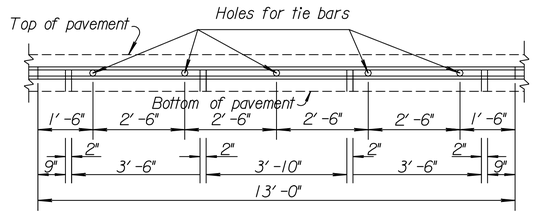
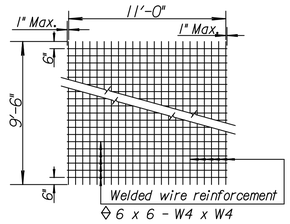
METAL STRIP FOR
LONGITUDINAL CONSTRUCTION JOINT (10'-0")



To be used only against forms. Shall not extend through contraction joints.

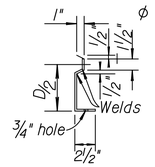
METAL STRIP FOR
LONGITUDINAL CONSTRUCTION JOINT (13'-0")



◊ 6 x 6 - W4 x W4

TYPICAL SHEET OF WELDED WIRE REINFORCEMENT
FOR SPECIAL BRIDGE APPROACH PAVEMENT

◊ Note: Epoxy coated #3 bars longitudinally @ 12" ctrs. & #3 bars transversely @ 18" ctrs. may be substituted for each layer of epoxy coated welded wire reinforcement.



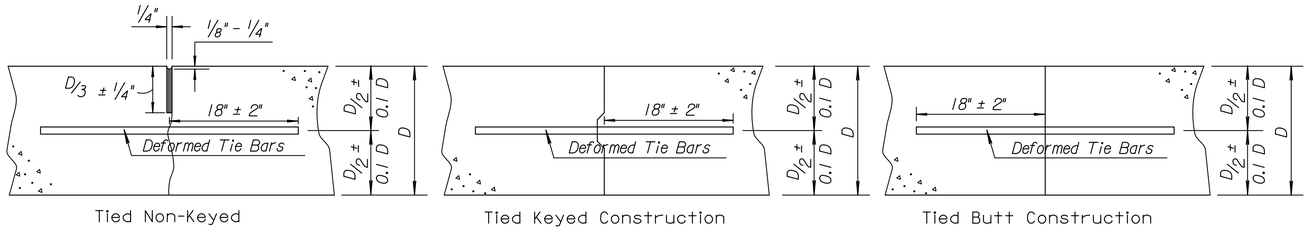
ϕ Snap-in leg or other approved designs may be used in lieu of welded leg.

SECTION OF RECESSED
FORM LEG

DETAIL OF LAP FOR WELDED WIRE REINFORCEMENT

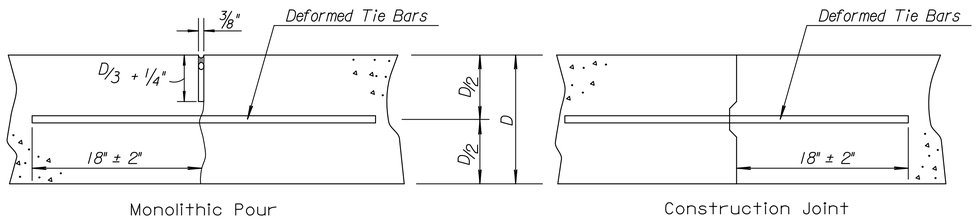
The lap shall extend beyond the first transverse or bag wire of each sheet.

The sheet shall be wired securely at the edges and at intervals not to exceed 2'-6" for the full width of the sheet. Approximate weight of welded wire reinforcement = 58 lbs. per 100 sq. ft. Other methods for fastening the sheets of welded wire reinforcement at the laps may be used with the approval of the Engineer.



LONGITUDINAL JOINTS

Note: For longitudinal construction joints the contractor has the option of using either the keyed or butt type.



TRANSVERSE JOINTS

Note: A construction joint is required when the concrete placement has been interrupted for a substantial length of time or at the end of a day's placement.

GENERAL NOTES

All work shall be done in conformity with the Standard Specifications applicable to the project.

The cost of all bars and joint material shown on this sheet is to be included in the bid price for Concrete Pavement.

At each planned transverse joint location, a 4 to 6 inch wide strip of the pavement surface shall be protected from the texturing operation to provide a transverse textureless surface centered over the joint sawcut.

All sawed joints on this project shall be filled with sealant in accordance with Standard Specifications.

The 6 inch edge curb shall be constructed integral with the approach slab shoulder.

All materials and work required for this construction shall be Subsidiary to the concrete approach slab.

Tie bars shall be evenly spaced along the length of the slab and no tie bars shall be within 12" of contraction joint.

PLAN VIEW

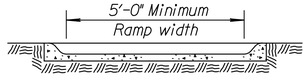
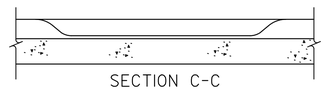
Reinforcement as in adjacent curb & gutter.

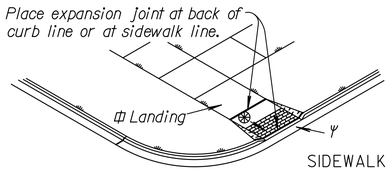
SECTION A-A



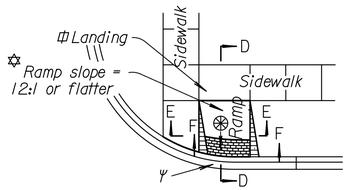
SECTION B-B



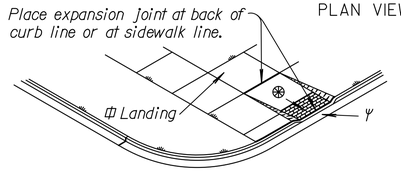
SECTION C-C



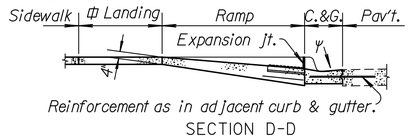
SIDEWALK RAMP TYPE 1



PLAN VIEW

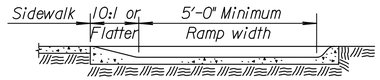


SIDEWALK RAMP TYPE 2

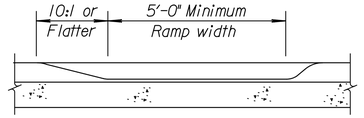


Reinforcement as in adjacent curb & gutter.

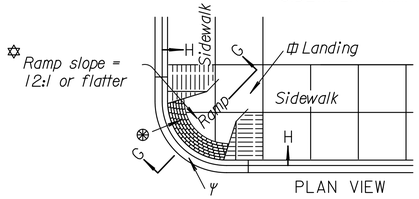
SECTION D-D



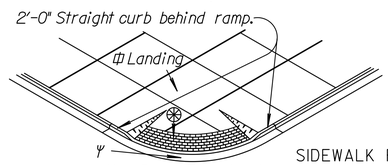
SECTION E-E



SECTION F-F

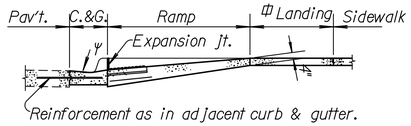


PLAN VIEW



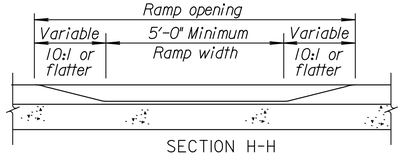
SIDEWALK RAMP TYPE 3

Use Ramp Type 3 where sidewalk occupies entire area between curb and property line.



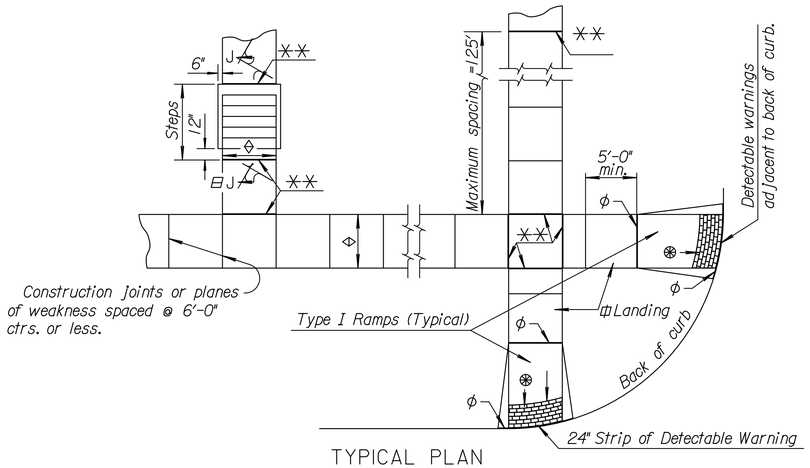
Reinforcement as in adjacent curb & gutter.

SECTION G-G

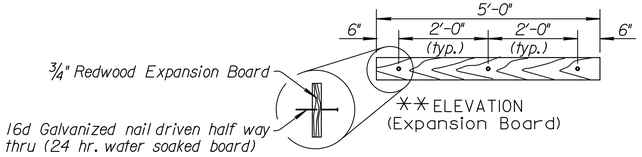


SECTION H-H

⊟ SECTION J-J see standard drawing RD725B for details of Steps and Handrail.



TYPICAL PLAN



For other than 5'-0" (width) use 6" from the end and balanced (3'-0" max.) nail spacing.

ϕ Expansion Joint (3/4" Redwood board) placed at either back of curb line or at sidewalk back of curb line or at sidewalk line.

XX Expansion Joint (3/4" redwood board) located as shown.

◊ Variable width (5'-0" min.). Entrance walk to be same width as approach walk. Use sidewalk width of 4'-0" where existing conditions prohibit use of 5'-0".

✡ New construction ramp slopes are 12:1 or flatter. Desirable ramp slopes for existing sites are 12:1 or flatter. Where space limitations prohibit construction of a 12:1 slope on existing sites, use the following slopes:
8:1 or flatter for a maximum rise of 3 inches
10:1 or flatter for a maximum rise of 6 inches

⏢ Use a landing slope of 50:1 or flatter. Landings are the same width as ramp and a minimum 5'-0" in length.

ψ Use a counter slope of 20:1 or flatter at the base of sidewalk ramps. Refer to standard drawing RD725A for additional curb and gutter details.

⊛ Detectable warning installation is typical and required on Sidewalk Ramps Type 1, Type 2, Type 3, median ramp crossings and other locations as shown in the plans. See standard drawing RD725A for additional details.

GENERAL NOTES

The details depicted here may not be appropriate for all locations. Designs shall meet this criteria on all new construction projects unless impracticable by site restrictions. For an existing sidewalk facility where the sidewalk will be replaced, sidewalk will be replaced according to this drawing to the maximum extent feasible.

Provide ramps at all corners street intersections where there is an existing or proposed sidewalk and curb. Provide ramps at mid-block walk locations for hospitals, medical centers and athletic stadiums.

Details shown on this sheet apply to all constrcution or reconstruction of streets, curbs or sidewalks. See standard specifications for additional information.

Restrict use of sidewalk ramp Type 2 to locations where it is not feasible to use Types 1 or 3.

Curb cut ramps are to be located as shown on the plans or as directed by the Engineer.

Do not place drainage structures in line with ramps except where existing drainage structures are being utilized in the new construction. Ramp locations should take precedence over the location of drainage structures.

Ramp sidewalks where the driveway curb is extended across the walk.

Construct ramp with uniform grade free of sags and short grade changes.

Place 3/4" redwood expansion joints flush with the surface at a maximum spacing of 125'. Place 3/4" redwood expansion joints at sidewalk junctions, see plan details. Where sidewalk abuts a curb place 3/4" redwood board expansion joint flush with the surface.

Place 1/2" premolded (Non-extruding, Type B) joint filler where sidewalk is parallel and adjacent to a rigid surface.

Slope sidewalk toward the street at a 50:1 or flatter. Slope or depress sidewalk where necessary to fit alleys and entrances see plans or at Engineer's direction.

Where clear width of sidewalk between top of ramp and building or other obstruction is less than 48 inches, slope the flared sides 12:1 or flatter.

Sidewalk shown to be constructed in back of an entrance shall be placed 6" thick with welded wire mesh reinforcement. Gauge and spacing of wires are the same as entrance pavement (See Reinforcement Diagram). Bid item will be "Sidewalk Construction (6") either with or without air entrainment.

~~Contractor may opt to use Concrete Grade 3.0 (AE) throughout for construction of steps, but all work and materials are paid for under the bid item "Grade 3.0 Conc. (Misc.)".~~

Surface texture ramp slope with a wooden float or brushed finish.

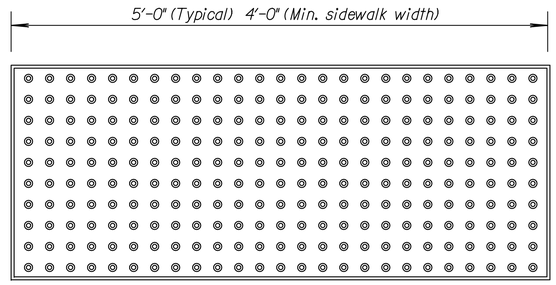
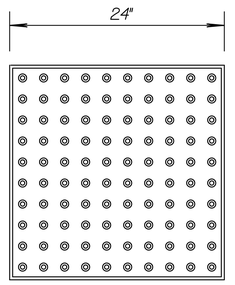
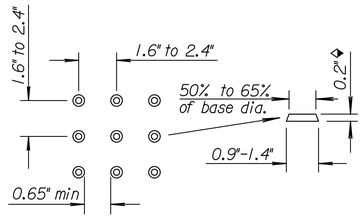
TYPICAL PLAN



COMPOSITE PANEL with TRUNCATED DOMES



PRESTRESSED RAMP PANEL with TRUNCATED DOME SURFACE



TRUNCATED DOME DIMENSIONS for SQUARE PATTERN (Parallel Alignment)

GENERAL NOTES

Details shown on Standard Drawing RD725 & RD725A may not be appropriate for all locations. Design new project construction to criteria shown on these drawings unless impracticable by site restrictions. For existing sidewalk replacement, follow these drawings to the maximum extent feasible.

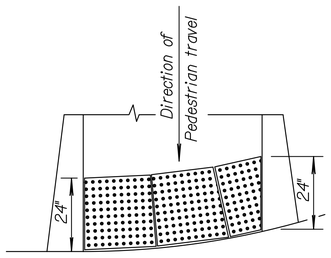
Use ~~Paving Brick, Prestressed or~~ Composite Panel (Truncated Dome Surface) units that meet the requirements of the Standard Specifications and comply with the American Disabilities Act. The panels shall be brick red in color.

Cover the ramp width and 24" length with truncated dome surface, see examples Standard Drawing RD725 & RD725A. Saw cut (only) bricks or panels with not less than 25% of a full brick or panel installed. Place Truncated Dome Bricks or Panels to align parallel in the direction of pedestrian travel.

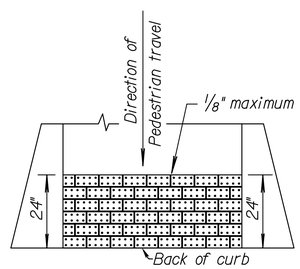
Prestressed or Composite Panels are installed in fresh concrete, Paving Brick require mortar bed and mortar sand, see Standard Specifications for requirements.

The entire ramp or median crossing will be bid as "Sidewalk Ramp" and payment is measured by the square yard. Materials and labor to install sidewalk ramp are subsidiary to the bid item "Sidewalk Ramp."

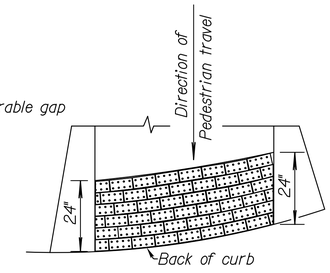
Composite Panel (Truncated Dome Surface) units shall be "Access Tile-Cast In Place Replaceable" or approved equal and shall be installed per manufacturer's recommendation.



RADIUS CURB DETAILS
Cut Prestressed Ramp Panels to fit.



STRAIGHT CURB DETAILS

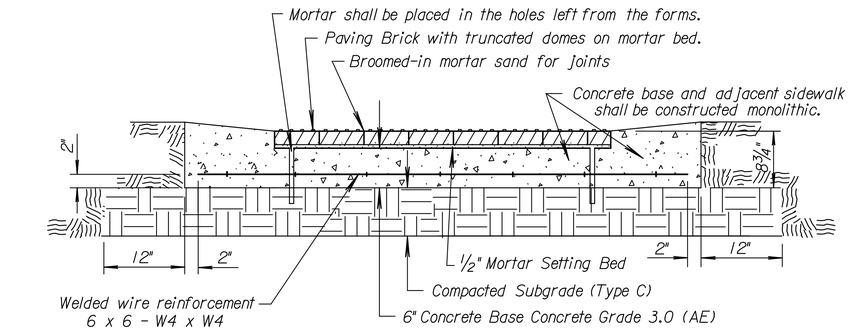


RADIUS CURB DETAILS

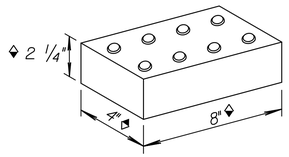
Installation shown for paving brick is running bond, use of other patterns is allowed with Engineer approval. Rotation 90° of Running Bond pattern is allowed to reduce space between bricks on radius installation, keep this space to a minimum. Place truncated domes on bricks in parallel alignment to pedestrian travel as shown.

Radius curb or greater than 5' width ramp will require more than one panel as approved by the Engineer. Limit number of panels installed at each site. Layouts shown are for example and may vary in the field.

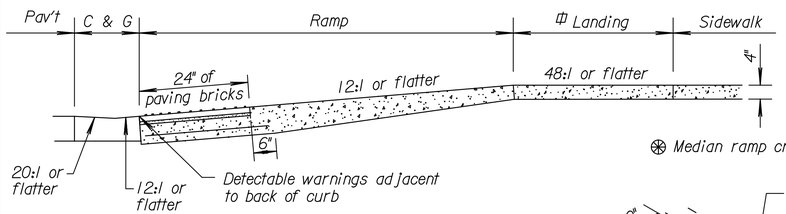
Acceptable with no mixing of types within an installation.



TYPICAL SECTION OF PAVER BRICK
SECTION A-A

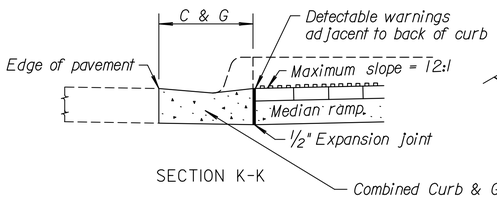


PAVER BRICK WITH TRUNCATED DOME SURFACE
These dimensions are nominal.

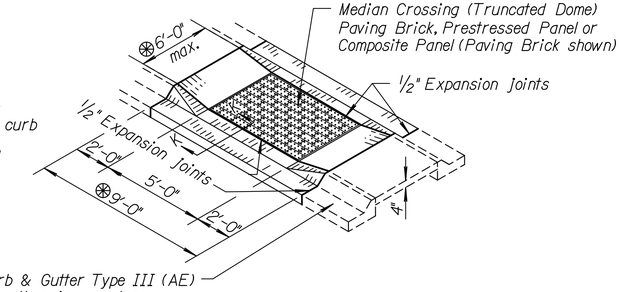


SECTION B-B

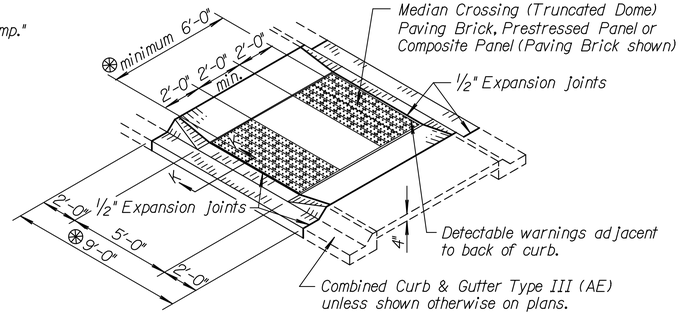
Median ramp crossing limits will be paid for as "Sidewalk Ramp."



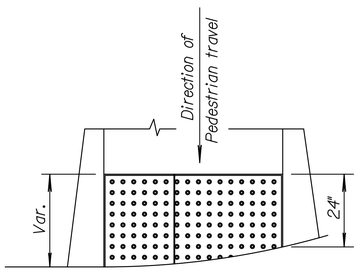
SECTION K-K



NARROW MEDIAN RAMP CROSSING
Note: A Median Ramp Crossing shall be constructed at Crosswalk locations.



WIDE MEDIAN RAMP CROSSING
Note: A Median Ramp Crossing shall be constructed at Crosswalk locations. Wider median islands will result in a 2' minimum gap between the truncated dome areas.



RADIUS CURB DETAILS (COMPOSITE)
Cut Radius from 3'-0" Long Composite Panel.

SECTION A-A

RW58

Note:
Excavation, backfill and any required testing of insitu material is subsidiary to the bid item "Concrete (Grade 4.0) (AE)".

Wall design is based on an allowable bearing pressure of 1.5 ksf. Contractor shall verify that the in-situ soil has an allowable bearing pressure greater than 1.5 ksf.

N.F. = Near Face
F.F. = Far Face

SUMMARY OF QUANTITIES *	
Concrete (Grade 4.0) (AE) Cu. Yds.	Reinforcing Steel (Grade 60) Lbs.
9.7	1,210

* These quantities are included in the Road Quantities.

DESIGN DATA

DESIGN SPECIFICATIONS:
AASHTO Specifications, 5th Edition and 2010
Interim Specifications. Load and Resistance Factor Design.

DESIGN LOADING:
HL-93
Design Dead Load includes an allowance of 15 psf for future wearing surface.

UNIT STRESSES:

Concrete (Grade 4.0) (AE) (SA)	f'c = 4 ksi
Reinforcing Steel (Grade 60)	fy = 60 ksi
Structural Steel (A709 Gr. 36)	fy = 36 ksi
Structural Steel (A709 Gr. 50W)	fy = 50 ksi
Structural Steel (M270 Gr. 50WT3)	fy = 50 ksi

TEMPERATURE: The design temperature for all dimensions is 60°F

QUANTITIES: Items not listed separately in the Summary of Quantities are subsidiary to other items in the proposal.

DIMENSIONS: All dimensions shown on the design plans are horizontal dimensions unless otherwise noted. Make necessary allowances for roadway grade and cross slope.

REINFORCING STEEL: All reinforcing steel dimensions are to the centerline of bars unless otherwise noted. All reinforcing steel shall conform to the requirements of ASTM A615, Grade 60.

Where non-coated bars come in contact with epoxy coated bars, they need not be coated.

CONCRETE: All concrete is bid as Concrete (Grade 4.0) (AE) (SA). All concrete is to be KCMMB 4K and is included in the bid item "Concrete (Grade 4.0) (AE) (SA)". Bevel all exposed edges of all concrete with a ¾" triangular molding, except where noted on the plans.

CONCRETE PLACING SEQUENCE: The sequence of placing concrete in the slab and curbs shall be as shown, or the Contractor may submit an alternate placing sequence for review. Submit the alternate placing sequence to the Engineer at the Preconstruction Conference. Include the proposed rate of concrete placement in C.Y./h, the plant capacity, placement direction, construction joint location, a description of the equipment used in placing the concrete, proposed admixtures, and the quantity of concrete in each placing segment. Any additional cost for the Contractor's alternate plan of placing concrete, including admixtures, shall be at the Contractor's expense and shall be considered subsidiary to the bid item, "Concrete (Grade 4.0) (AE) (SA)". Approval of the Contractor's alternate sequence is required prior to placement of concrete in the deck.

Place and hand vibrate all concrete for the abutments above the construction joint to the bottom of deck elevation just prior to the normal paving train operations. Do this work in a manner to avoid cold joints in either the slab or in the abutment.

DECK PROTECTIVE SYSTEM: Epoxy coat all reinforcing steel in the deck slab and rails.

CONSTRUCTION LOADS: Limited traffic is permitted on the new one-course deck during the curing period. Keep any exposed deck wet during the curing period. See KDOT Specifications Section 710 Tables 710-1 & 710-2 for additional information.

MULTI-LAYER POLYMER CONCRETE OVERLAY: No concrete curing membrane will be used on structures with a polymer overlay. Roughen the bridge deck surface using a burlap drag attached to the finish machine. When the date and temperature requirements of the specifications are met, grind profile, place a polymer overlay, and apply permanent pavement markings on the bridge deck. When the date and temperature requirements are not met, complete any required grinding and apply temporary pavement markings. Apply the polymer overlay according to the next available date(s) and temperature allowed per the current specifications. See KDOT specification for complete information.

ANCHOR BOLTS: Anchor bolts will adhere to KDOT Standard Specification Section 1600 (Grade 105 at Piers and Grade 55 at Abutments) with the following exception: the threads may be rolled or cut.

BEARING (STEEL REINFORCED ELASTOMERIC): Elastomeric Bearing Device shall be factory bonded to the steel sole plate and the steel base plate by a vulcanization process. The steel sole plate, steel base plate and swedge anchor bolt are subsidiary to the bid item, "Bearing (Steel Reinforced Elastomeric)" and shall be furnished by the bearing device fabricator.

BEARING (STEEL REINFORCED ELASTOMERIC) (Method A): Bearing devices at piers shall be fabricated with an elastomer satisfying:
Shore A Durometer Hardness of 60
Low Temperature Grade 3 requirements
Type A certification for elastomeric bearing device acceptance is required.
Include design method and all material properties on shop drawings.

ABUTMENT AGGREGATE DRAIN: See the General Notes on the "Abutment Aggregate Drain" sheet.

BACKFILL COMPACTION: Compact backfill at the abutments.

CONDUIT SYSTEM INSTALLATION: The Contractor shall install the conduit, conduit hangers, and PVC conduit sleeves at the abutments for the AT&T utility as shown on the plans. Material required, including conduit, conduit hangers, threaded rods, nuts, bolts and washers shall be in accordance with KDOT specifications and be provided to the Contractor by AT&T. The Contractor will coordinate with AT&T and schedule the conduit installation. Conduit shall be installed by the Contractor in accordance with KDOT specifications. The bid item "Electric Conduit (4.0") (Non-Metallic) (Installation Only) (Non-Participating)" will be full compensation for the additional time and labor required by the Contractor to install the conduit system.

SHEET NO. OF		SCALE		APP'D			
DESIGNED	DT	DETAILED	MCS	QUANTITIES	DT	CADD	
DESIGN CK.	DWH	DETAIL CK.	DWH	QUAN. CK.	DWH	CADD CK.	

STATE	PROJECT NO.	YEAR	SHEET NO.	TOTAL SHEETS
KANSAS	046 N-0576-01	2013	14	99

FALSEWORK PLANS: A licensed Professional Engineer shall design the falsework details. Details shall bear the seal of a licensed Professional Engineer. See the Bridge Design Manual, Section 5.1 "Review and Approval of Falsework Plans", for a listing of items to be included on the falsework plan. Submit electronic plans conforming to 105.10(b) of the Standard Specification with details in compliance with KDOT Specifications to the Field Engineer for review.

FALSEWORK INSPECTION: This project has falsework plan requirements which are considered "Category 1" by KDOT specifications. The falsework designer of record will conduct an inspection of the as-built falsework. The bid item, "Falsework Inspection" is full compensation for all materials, labor and equipment. See KDOT specifications.

FALSEWORK PLANS AND SHOP DRAWINGS: Use the U.S. Customary system of units on falsework plans and shop drawing details.

STRUCTURAL STEEL: The rolled beams, bearing stiffeners and splice plates shall meet AASHTO M270 Gr. 50WT3 requirements except as noted. All other structural steel shall meet ASTM A709 Gr. 50W, unless noted otherwise. Shop and Field Splices shall be made only where shown on the Contract Plans as a "splice" or as an "optional splice." Elimination of any "splice" may be requested.

MISCELLANEOUS STEEL: Steel for the Girder Chairs may be A36. Payment for this item shall be subsidiary to ASTM A709 Grade 50W Steel.

SHOP DETAILS: Reference blocking diagrams on the shop details to a level line running the entire length of the girder.

FABRICATION OF FIELD SPLICES: Prepare joints for the field splices in accordance with KDOT Specifications. Use Type "B" shop laydown.

WELDING: Material, fabrication and construction shall conform to KDOT Specifications. On the shop drawings, show a code or symbol at the tail of the weld symbol, which refers to an approved pre-qualified weld procedure.

WELDED STUD SHEAR CONNECTORS: Weld Shear Stud Connectors with automatically timed stud welding equipment connected to a suitable power source. All stud welding shall conform to KDOT Specifications.

BOLTS: All bolts, nuts and hardened flat washers shall conform to the heavy hex structural requirements of ASTM A325, Type 3, and KDOT Specifications unless otherwise noted. Direct Tension Indicators (DTIs) are to comply with the requirements of the latest edition of ASTM F959. No allowance will be made for high strength bolts used for permanent or temporary connections. This work is subsidiary to the bid item, "Structural Steel".

BOLTED CONNECTIONS: Girder Connections: Use $\frac{7}{8}$" diameter heavy hex structural bolts for the main member connections. Use $\frac{15}{16}$" diameter bolt holes. Do not ream during field erection. Accurately align all connections by driving $\frac{15}{16}$" diameter drift pins in all corners and in 1/4 of the remaining holes in each plate. See KDOT Specifications.

Secondary Member Connections: Use $\frac{3}{4}$" diameter heavy hex structural bolts for the secondary member connections. Use $\frac{13}{16}$" diameter bolt holes. Oversized and/or slotted holes, as specified in the KDOT Specifications, may be used in only one of the two members connected and must be shown in the approved shop drawings. Oversized and/or slotted holes may require additional standard hardened washers or plate washers. Report to the Engineer prior to any required field reaming that will remove more than $\frac{1}{4}$" of material from one ply of the connected parts.

Use Direct Tension Indicators (DTIs) on all high strength bolts. Place the DTI under the bolt head and turn the nut to tighten. This method is preferred whenever possible. Face the protrusions on the DTI to the underside of the bolt head. Place a hardened flat washer under the nut. See KDOT Specifications.

FILLETS:
Construct the finished deck to plan grade by varying the depth of the fillet over the beam to provide for beam profile, concrete dead load deflection and, if necessary, vertical curvature. After the beams are completely erected and the falsework bents are removed, profile each beam. Correct any variation between the actual profile and the concrete dead load deflection shown in the plans by varying the depth of the concrete fillets over the beams so that the finished floor is constructed to the theoretical grade. The Contractor shall submit a fillet diagram that shows fillet depths at tenth points of each beam. The fillet diagram shall be submitted to the Engineer 14 days prior to pouring the bridge deck. The minimum depth of the slab over the beam shall be $8\frac{1}{2}$ inches.

The theoretical amount of concrete required for the fillets is 11.6 C.Y. This amount of concrete is included in the Summary of Quantities. Any additional concrete required to construct the fillets will be subsidiary.

ERECTION: Bring each line of girders to the correct line, grade (or relative grade) and camber, and secure in place prior to connection of the girder field splices. Provide falsework bents as necessary to maintain the correct line and elevation. Leave the falsework bents in place until all girder splice connections are completed. Submit information which clearly shows the proposed layout and use of falsework bents. The Engineer shall approve such information prior to erection of structural steel.

ERECTION PLANS:
This is a Category B Structure. Submit detailed Erection Plans to the State Bridge Office (or Bureau of Local Projects) at least 4 weeks before beginning the erection process. Portions of the submitted details shall bear the seal of a licensed Professional Engineer. Identify, on the Erection Plans, the Erection Supervisor required by KDOT Specifications. No structural erection work will begin without approved erection plans.

PAINTING: Blast clean all surfaces of all weathering steel, including all contact surfaces of bolted connections, to meet SSPC-SP6 Specifications (latest Revision). Blast clean to meet SSPC-SP10 Specifications and prime coat the embedded portion of the girders, including the abutment diaphragms; the top flanges, including the shear studs; and the top flange splice plates. Paint the exterior surfaces of the exterior girders in accordance with KDOT Specifications.

PAINTING: The shop coats applied to Structural Steel shall conform to an inorganic zinc primer.

"Touch-Up": Prepare and paint all bolts, nuts, studs, and other small areas of damaged paint (1 yd^2 or less), requiring touch-up, with an approved organic zinc primer.

Top Flanges: (Studs applied in the shop) Apply a 3 mil primer coat of an approved inorganic zinc primer to the tops of the top flanges and to the studs.

(Studs applied in the field) Shop Work - Blast clean the tops of the top flanges to SSPC-SP10 Specifications (latest Revision).

Field Work - Blast clean the tops of the top flanges to SSPC-SP6 Specifications (latest Revision) before the studs are applied. After the studs are applied, blast clean the tops of the top flanges and the studs to SSPC-SP6 Specifications and paint with an approved organic zinc primer to a minimum dry film thickness of 3 mils.

BRIDGE EXCAVATION: All excavation shall be Class III. See the Bridge Excavation sheet for the limits of pay excavation.

BRIDGE BACKWALL PROTECTION SYSTEM: Apply a Bridge Backwall Protection System to the approach side of the abutments and the wings in accordance with KDOT Specifications and the manufacturer's recommendations. Cover the abutments and wings to the limits shown on the details, not including the top of the pavement rest. Prior to backfilling, repair any damage done to the system at no extra cost to the State. See the General Notes on the "Abutment Aggregate Drain" sheet.

BRIDGE DRAINS: Galvanize and apply a two-component, 98% polymeric epoxy, amido-amine primer tiecoat of approximately 1-$2\frac{1}{2}$ mils in thickness to the drains, prior to application of a water-borne acrylic finish coat. Follow the manufacturer's recommendations for application and cure time.

REMOVAL OF EXISTING STRUCTURE: Removal of existing superstructure is included in the bid item, "Removal of Existing Structures", Lump Sum. All materials removed from the existing structure shall become the property of the Contractor. Remove this material from the site.

DRILLING AND GROUTING: This item shall consist of grouting reinforcing steel, anchor bolts, tie bars, or dowel bars into the existing concrete, where required by the Engineer, with an epoxy grout. Follow KDOT Specifications 842 and any associated Special Provisions. Follow the manufacturer's directions for mixing, application and curing. The tools, materials, labor and incidentals necessary to complete the work shall be paid for per each by the bid item "Drilling and Grouting".

DEMOLITION PLANS: This is a Category B Demolition. Submit detailed Demolition Plans to the Field Engineer at least 2 weeks before the demolition meeting. Identify, on the plans, the Demolition Supervisor meeting the requirements of the KDOT Specifications. No Demolition work will begin without approved Demolition Plans. A Licensed Professional Engineer is not required.

TEMPORARY SHORING: The bid item "Temporary Shoring" includes all labor and material necessary to furnish shoring at the locations shown on the plans for the temporary bracing of the embankment during excavation. Maintain the temporary shoring until the Engineer authorizes its removal. The temporary shoring plans are to be designed and sealed by a registered Professional Engineer. Submit design calculations and shoring plans to the Field Engineer for review 3 weeks before work is scheduled to begin. Work shall not begin until the Engineer grants approval.

SLOPE PROTECTION: Remove and replace existing concrete slope protection to the limits required for new construction. Removal and replacement of existing concrete slope protection shall be subsidiary to the bid item "Rip Rap (Reinforced Concrete) (4")".

TRAFFIC CONTROL: The bridge will be closed to vehicular traffic during construction. Pedestrians will use the bridge sidewalks during construction. See traffic control sheets for details.

STREAM BED: Work done on the project shall not impact the stream bed.

TYPICAL PIER DEMOLITION

Notes:

Remove existing pier beam and abutment beam reinforcement within limits of concrete removal to avoid conflict with new construction.

Removal shall conform to KDOT Standard Specifications, Section 202.

The contractor shall take care not to damage existing concrete that is to remain. Use chipping hammers no larger than 15 pound class to remove concrete within 6" of concrete that is to remain. Use chipping hammers no larger than 35 pound elsewhere. Damage done to concrete that is to remain will be repaired at the contractor's expense.

Removal of existing superstructure and partial removal of existing substructure is included in the bid item, "Removal of Existing Structures", Lump Sum. All materials removed from the existing structure shall become the property of the Contractor. Remove this material from the site.

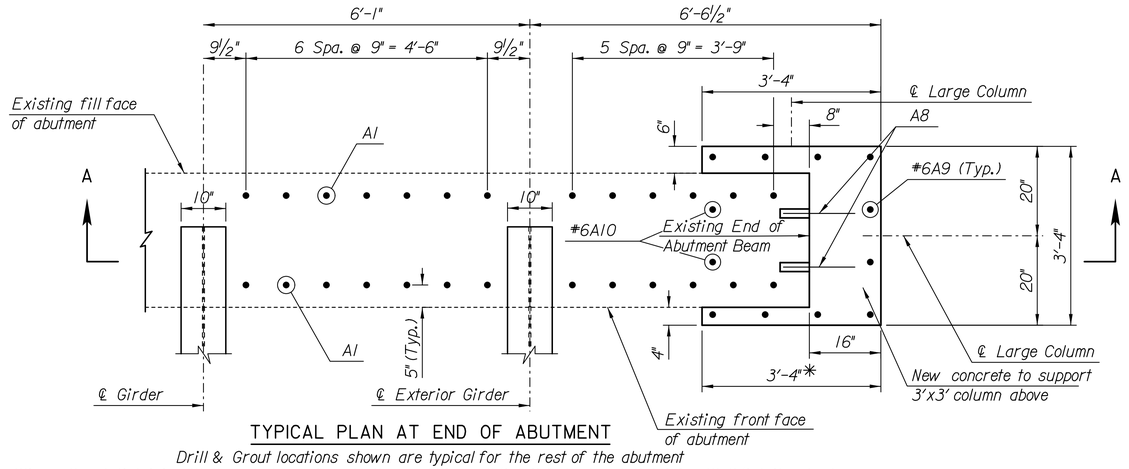
TYPICAL ABUTMENT SECTION

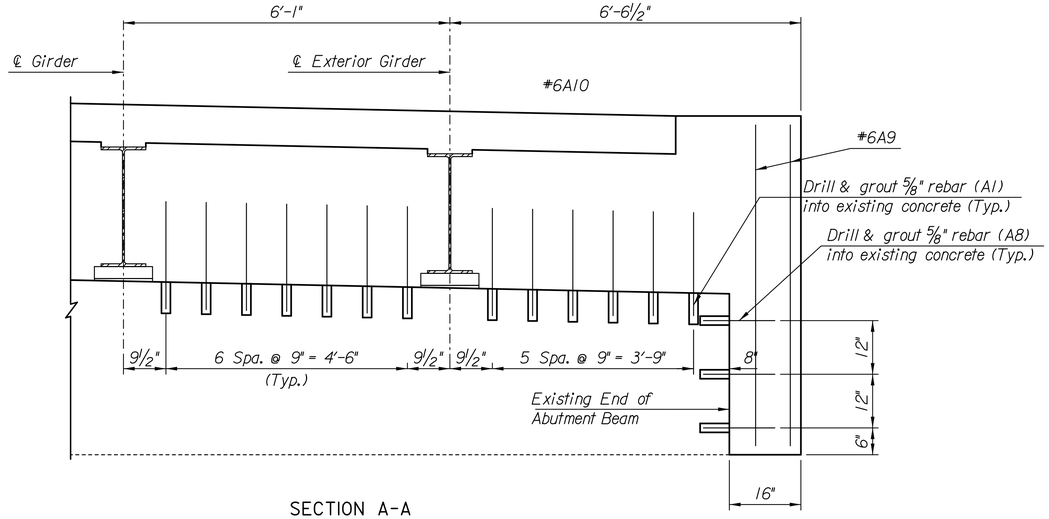
Drill & grout bars into the existing abutment. This work will be paid for per each in the bid item "Drilling & Grouting".

Depth of Drill & Grout for A1 and A8 bars shall be in accordance with the grout manufacturers recommendations. Lengths of the A1 and A8 bars in the bill of reinforcing assume a 6" embedment depth. Adjust the length of the A1 and A8 bars accordingly. Use a pachometer prior to drilling to locate and avoid existing reinforcing steel.



TYPICAL PLAN AT END OF ABUTMENT

Drill & Grout locations shown are typical for the rest of the abutment
Wingwall and Retaining Walls not shown for clarity, see "Wingwall Details" sheet and Retaining Wall Details sheets.



SECTION A-A

Drill & Grout locations shown are typical for the rest of the abutment
Wingwall and Retaining Walls not shown for clarity, see "Wingwall Details" sheet and Retaining Wall Details sheets.

Note:
Cast 4"Ø PVC conduit sleeves into the new diaphragm concrete. Coordinate layout of sleeves with AT&T. Shift abutment reinforcing as necessary to avoid conduit sleeves. Cost of providing and installing conduit sleeves shall be subsidiary to the bid item "Electric Conduit (4.0") (Non-Metallic) (Installation Only) (Non-Participating)".

See "Railing & Aesthetic Column Details" sheet for column reinforcing embedded in abutment.

GENERAL NOTES

GEOSYNTHETICS: Use material that complies with KDOT Specification Section 1710 Class 2 subsurface drainage fabric. Place the Class 2 subsurface drainage fabric on graded and compacted material shaped as shown. Allow for enough material so that the top can be overlapped and the end folded to completely enclose the aggregate drain. Place the perforated drain pipe and couple to non-perforated pipe as shown. Allow the non-perforated pipe to pass through a hole carefully cut in fabric. Place aggregate within fabric to just leave the top of the pipe visible. Verify the slope of the pipe, that it is not damaged or displaced and that the couplers are firmly coupled. Continue to back fill to the elevation and shape shown. Lap the top of the fabric a minimum of 3'-0", fold and wrap the ends to enclose the drainage materials. Secure the folds and wraps by sewing or approved methods.

AGGREGATE: Use aggregates that complies with KDOT Specifications for SB-1, SB-2 or SB-3.

BASE COURSE REINFORCEMENT: Use "Base Course Reinforcement" that complies with KDOT Specification Section 1710 or approved material. Place this material in uniform layers without gaps or sags per the manufacturer's recommendations.

GEOFOAM: Use "Geofoam" that complies with KDOT Specification 07-2005 latest revision or approved material. Bond this material to the back wall protection using materials recommended by the manufacturer.

SOIL CAP: The soil will have a Unified Soil Classification of CL or ML according to ASTM D2487. Compact to Type A, MR-90.

PIPE: Place perforated pipe within the limits and use non-perforated pipe outside the limits of the Abutment Aggregate Drain.

ABUTMENT AGGREGATE DRAIN: The Bridge Contractor shall excavate to the limits shown on the Bridge Excavation Sheet. Backfill, compact & grade the cohesive soil to the limits shown. Place the bridge backwall protection, geofoam, geotextile, perforated pipe, alternating layers of aggregate and base course reinforcement as shown. Place the outlet pipe, the CMP, and the backfill. Guide post and coarse aggregate are subsidiary to this bid item. Guide post and coarse aggregate are not required if the CMP empties onto Slope Protection. Enclose the entire Abutment Aggregate Drain with the geotextile

BRIDGE BACKWALL PROTECTION SYSTEM: Apply a non coal-tar Bridge Backwall Protective System to the approach side of the abutments and the wings in accordance with KDOT Specifications and the manufacturer's recommendations. Cover the abutments and wings to the limits shown on the details. Repair any damage done at no charge to the state.

Compact the abutment backfill. See the KDOT Specifications.

Perforated pipe and non-perforated outlet pipe shall be corrugated polyethylene tubing conforming to the KDOT Specifications.

Fit the outlet pipe end section with 1/4" galvanized mesh screen to prevent the entrance of rodents. Seal the joint between the outlet pipe and the end section with a joint sealer. Place Coarse aggregate at the outlet end as shown.

COHESIVE SOILS: Grade the bottom surface of the excavated area to drain as shown. Backfill this area with a cohesive type of soil. The soil will have a Unified Soil Classification of CL, CH, ML or MH according to ASTM D2487. Classification System with a minimum plasticity index of 13. Compact the material to Type A, MR-90 specifications. If the plasticity index cannot be met add and mix Bentonite, to the soil prior to placement and compaction so that the PI≥ 13.

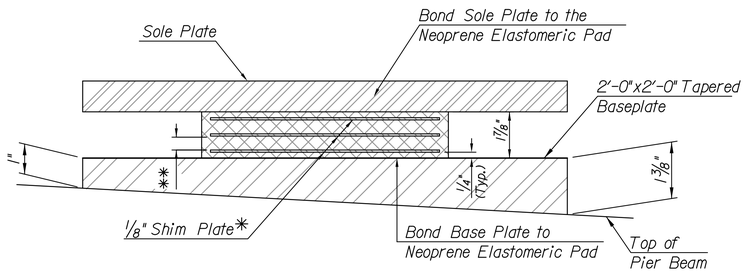
SECTION B-B

GIRDER CHAIR AT ABUTMENTS

(At the Contractor's option, A709 Gr. 36 Steel may be used for girder chairs.)

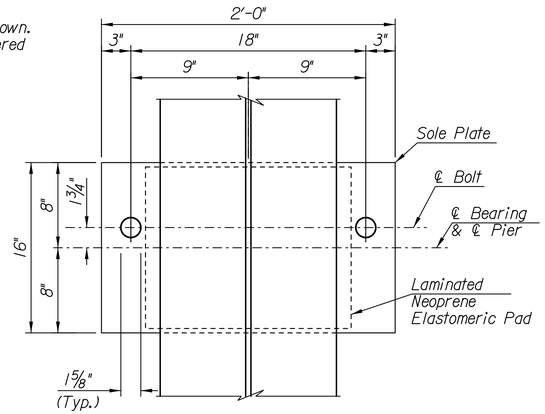


* *The required shim plates shall be placed between layers of Elastomer and molded together to form an integral unit.*

** *Layers of ½" Elastomer Alternating with ⅛" Steel Shim Plate.*

LAMINATED NEOPRENE ELASTOMERIC BEARING DEVICE @ PIERS

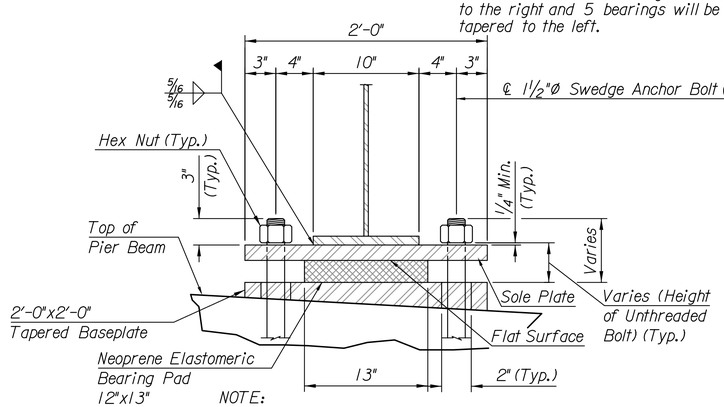
Note:
Baseplate tapered to the right is shown. At each pier, 7 bearings will be tapered to the right and 5 bearings will be tapered to the left.



PART PLAN VIEW SHOWING SOLE PLATE

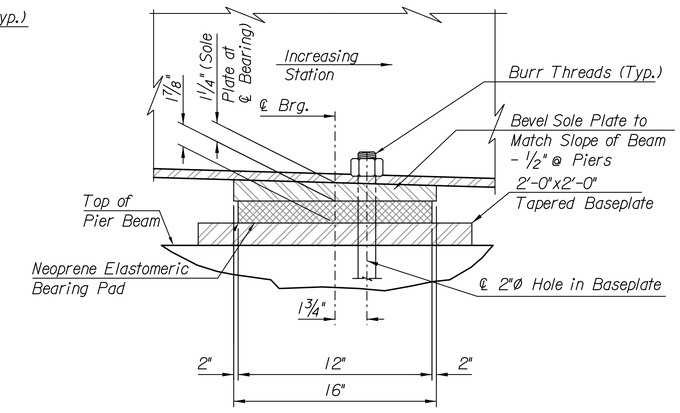
GIRDER CHAIRS AT ABUTMENTS

Note:
Baseplate tapered to the right is shown. At each abutment, 7 bearings will be tapered to the right and 5 bearings will be tapered to the left.



NOTE:
Limit Maximum Temperature at face of Sole Plate next to the neoprene pad to 300°F during welding of the beam.

END VIEW



SIDE VIEW

GENERAL NOTES:

Elastomeric Bearing Device shall conform to KDOT Standard Specifications and current Special Provisions.

The sole plate shall be furnished with the bearing and field welded to the girders. The base plate shall be furnished with the steel bearing.

Structural steel for sole plate and base plate shall be ASTM A709 Grade 50W and shall be coated with a minimum of two coats of inorganic zinc primer (125 micrometers minimum). After erection, apply the water-borne acrylic finish coat to the exposed surfaces of the sole plate and base plate.

The accepted quantity of elastomeric bearing assemblies, complete-in-place, will be paid for per each for "Bearing (Steel Reinforced Elastomeric)".

Anchor bolts shall meet the requirements of KDOT Specifications for Swedged Anchor Bolts, Type II (105 ksi @ Piers & 55 ksi @ Abutments). Anchor Bolts shall be furnished with heavy hexagonal nuts and washers per KDOT Specifications.

All structural steel for the anchor bolts and heavy hexagon nuts shall be hot dipped galvanized in accordance with ASTM A153.

Payment for the sole plate, base plate, anchor bolts, heavy hexagon nuts and washers, drilling and grouting shall be included in the cost of the bearing device and be subsidiary to "Bearing (Steel Reinforced Elastomeric)".

Anchor bolts shall be installed by drilling and grouting. Depth of drill and grout shall be according to the grout manufacturer's recommendations. Use a pachometer to locate and avoid existing reinforcing steel prior to drilling.

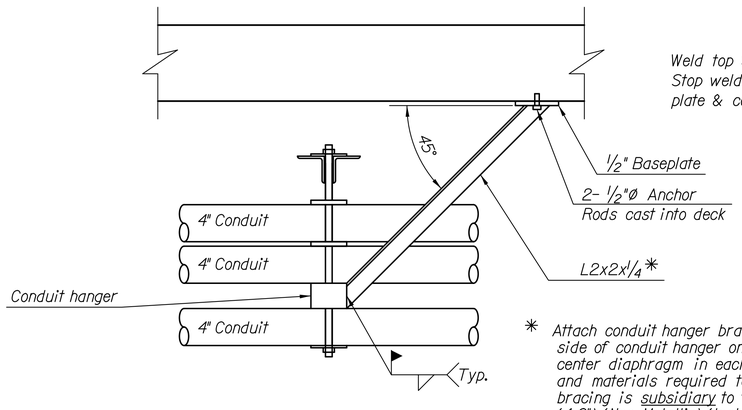
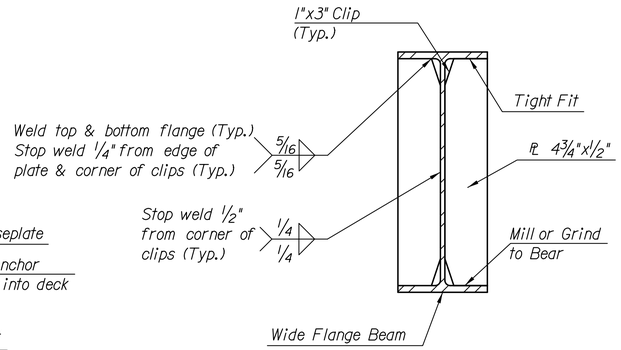
DIAPHRAGM AT CONDUIT LOCATIONS DETAIL

AT&T conduit and conduit hangers to be provided by AT&T and installed by Bridge Contractor.

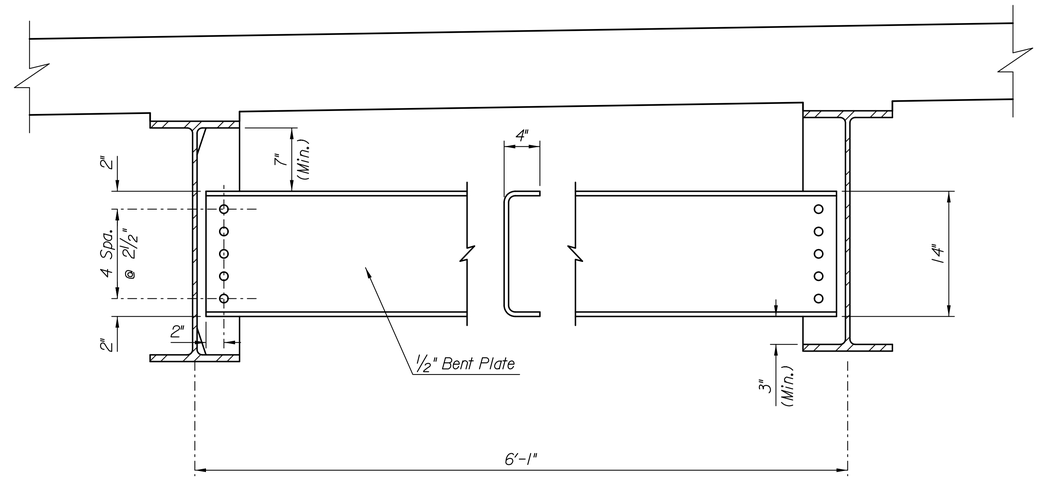


SECTION OF CONDUIT HANGER

* *Attach conduit hanger bracing on each side of conduit hanger only at center diaphragm in each span. Cost of labor and materials required to install conduit bracing is subsidiary to "Electric Conduit (4.0") (Non-Metallic) (Installation Only) (Non Participating)".*



TYPICAL BEARING STIFFENER AND DIAPHRAGM CONNECTION PLATE



TYPICAL DIAPHRAGM DETAIL

Notes:
All main load-carrying members shall meet AASHTO M270 (Gr. 50WT3) requirements.
Main load-carrying members include all rolled beams, bearing stiffeners and splice plates.
All other structural steel shall meet ASTM A709 (Gr. 50W) requirements.

All bearing stiffeners shall be placed normal to girder. All intermediate diaphragm connection plates shall be placed parallel to intermediate diaphragms.

All bearing stiffeners and girder ends, except at field splices, shall be vertical after final erection. All other stiffeners and all field splices shall be normal to the top flange.

See "Drain Details" sheet for details and locations of Drain Tube Mounting Connection Plate.

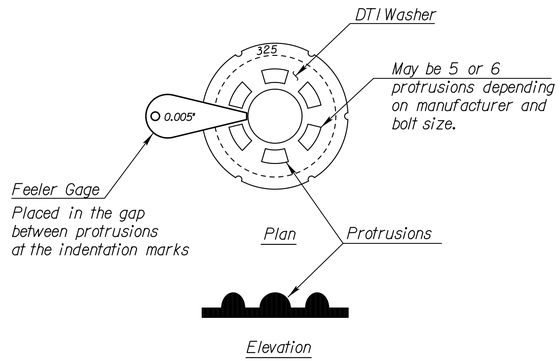
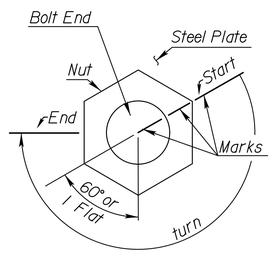
TYPICAL BOLT AND
DIRECT TENSION INDICATOR (DTI)

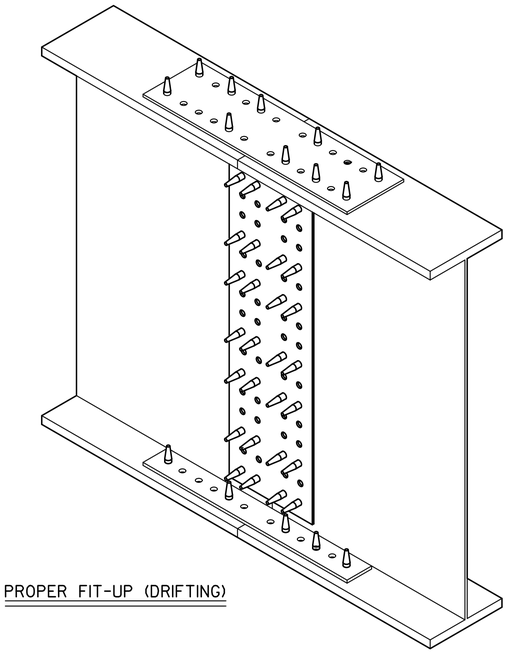


TYPICAL DIRECT TENSION INDICATOR (DTI)



REQUIRED MARKING DETAIL

(shows calibrated turn = 3½ flats from snug tight condition). Example only, calibrated turn may be more or less than shown.



PROPER FIT-UP (DRIFTING)

Production Bolt Tightening

1. Install bolts and tighten to "snug tight" in a pattern, starting at the center of the splice and working toward the edge. On large girders this may have to be done twice, as the center bolts will become loose as plates are "Ironed out". This step is important because typically, any variation in results during production bolting is the result of a change in the materials, lubricant or equipment used to take the bolts to a "snug tight" condition during the calibration process.

2. Mark all of the bolts, nuts and the plate as shown in the marking detail. Mark the socket with a start and stop point. The stop point corresponds to the target rotation determined earlier.

3. Align the start mark on the socket with the line on the plate. While the bolt is being backed up, turn the nut until the stop mark on the socket lines up with the start mark on the plate.

4. Repeat with all bolts of the same length in the splice.

Acceptance and Rejection of Bolts

1. The Engineer will check all bolts with a feeler gage.

2. All nuts must be turned at least the target rotation beyond "snug tight".

3. All DTI's must have at least 3 refusals of the 0.005" gage.

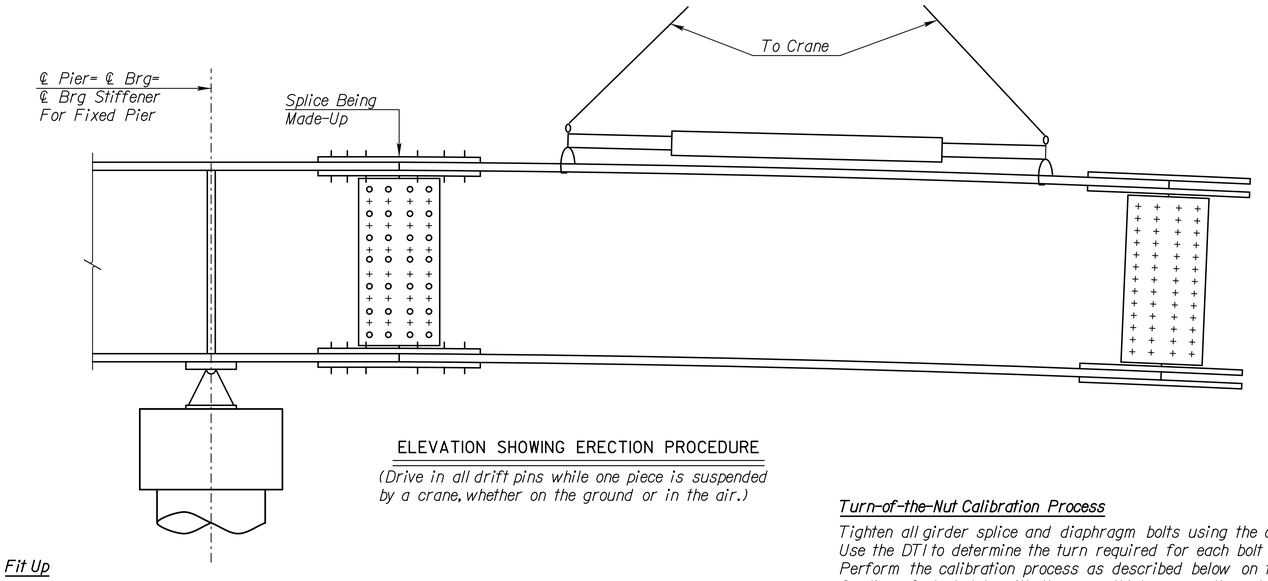
4. If all gaps refuse the 0.005" gage, and the nut, plate and bolt are not marked, reject the bolt.

5. If all gaps refuse the 0.005" gage, and the turned element has not been rotated more than 45° beyond the calibrated turn, accept the bolt.

6. If all gaps refuse the 0.005" gage, and the turned element has been rotated more than 45° beyond the calibrated turn, reject the bolt.

For additional information see the structural steel section of the Bridge Construction Manual.

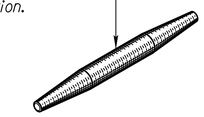
Suggested Impact wrench models:
CP 611
IR 2940
Cleco WS2110
ATP 1011/1040
Norbar PT1500



ELEVATION SHOWING ERECTION PROCEDURE

(Drive in all drift pins while one piece is suspended by a crane, whether on the ground or in the air.)

Drift Pin Diameter = Hole Diameter
Hole Ø = 15/16" for girder splice
Hole Ø = 13/16" for X-frame or diaphragm connection.



DRIFT PIN

Fit Up

During the fit up, install drift pins in all corner bolt holes, plus 25 percent of the bolt holes (as a min.), evenly distributed throughout the splice. Fill at least 25 percent of the bolt holes with high strength bolts. Fully tighten these bolts by the calibrated turn-of-the-nut method before removing any drift pins or moving the members. These bolts may be either erection bolts or production bolts. Erection bolts are used during fit up, to compress the plies of the splice to achieve a snug condition. Erection bolts are the property of the Contractor and do not remain in the bridge permanently. Erection bolts must be A325, and can be reused. Erection bolts are required when the abutting plates are of different thickness and no fill plate is provided. This situation usually results in a slight bending of the splice plates. If erection bolts are not used, the DTI's may fully compress before the plates are in firm contact. This would be cause for rejecting the splice. Clearly mark the erection bolts so that they are not left in the splice.

Erection

Two independent crews will survey the bearing seat elevations. The Engineer will verify that the results of those surveys show that the bearing seat elevations are within ± ¼ inch of the plan elevations before erection begins. Use the blocking diagram, as shown on the shop drawings, when erecting the beams/girders on the ground. Do not lift the assembled pieces into position until at least 25 percent of the holes are filled with fully tightened bolts. Locate the centerline of the bearing stiffener with the centerline of bearing device. Secure the beams/girders to the top of the pier cap prior to placement of the bearing device anchor bolts.

Turn-of-the-Nut Calibration Process

Tighten all girder splice and diaphragm bolts using the calibrated turn-of-the-nut method. Use the DTI to determine the turn required for each bolt diameter & length. Perform the calibration process as described below on the actual beam splice or using 3 plies of steel plate with the same thickness as the actual splice.

1. Bring at least 25 percent of the bolts in the splice to a "snug-tight-condition". "Snug tight condition" is defined as (with all plies in firm contact) "the full effort of a man on a spud wrench". Usually a smaller impact gun (½" drive) is used to snug the splice and a larger impact gun (1" drive) is used for final tightening. This is preferred over the use of a spud wrench. Production bolting and calibration must use the same tools and lubricating procedures. If an impact wrench is used to "iron the plates" and snug the bolts for calibration, then an impact wrench must be used during the snugging process during production bolting.

2. See "Required Marking Detail" (choose a bolt at the center of the splice and recheck snug on adjacent bolts)
- *a. Mark the outside of the socket at one of the corners.*
- *b. Mark the bolt, plate, and nut at a corner with a start line.*
- *c. Align the mark on the socket with the start mark on the bolt end.*
- *d. While holding a backup wrench on the head of the bolt, turn the nut ½ turn (3 flats).*
- *e. Record the number of refusals.*
- *f. If all of the gaps refuse, go to another bolt and turn the nut 2 flats (1/3 turn).*
- *g. If there are fewer than 3 refusals turn the nut an additional ¼ of a flat (15 degrees).*
- *h. Repeat step g, turning the nut 1/3 of a flat or less each time, until all of the gaps refuse the feeler gage. Record the amount required to cause all of the gaps to refuse the feeler gage. This is the target rotation.*

3. Repeat this process for each bolt diameter and length.

BASEPLATE DETAILS FOR FENCE END POST ON BRIDGE

Note:
See architectural sheets for details of fence, handrail and columns. All materials & labor required to construct the aesthetic details on the columns, including cast stone caps, formliner, stain, tiles, cast stone bases & cast stone bands shall be subsidiary to "Concrete (Grade 4.0) (AE) (SA)".

BRIDGE HANDRAIL, PEDESTRIAN FENCE & CONCRETE COLUMN GENERAL NOTES:

All Tube Sections shall be ASTM A500 Gr. B.

All Steel Sections shall be Hot-Dip Galvanized per ASTM A123. All anchor bolts shall be Galvanized per ASTM A153. All Steel Sections shall be Powder Coated to match Federal Standard 595B, Color 27038.

Approval of Shop Drawings and Materials is required before fabrication or installation begins.

Provide Galvanized Shims to erect the Fence Posts vertically. The cost of Shims shall be subsidiary.

All Labor and Materials required to Construct and Install the Fence on the bridge & on the retaining walls is considered completely covered by the bid item "Fence (Pedestrian)".

All Labor and Materials required to Construct and Install the Handrail on the bridge is considered completely covered by the bid item "Bridge Handrail (Metal) (1'-10")".

The assemblies shall be shop welded and ground smooth prior to painting. No field welding will be permitted.

The Contractor shall field verify the as-built dimensions, grade and profile of the bridge prior to the fabrication of the Pedestrian Fence and Handrail. The rails of the Pedestrian Fence and Handrail shall be parallel to the roadway profile. All posts shall be plumb.

All misc. steel and plates shall be ASTM A36.

All welding shall conform to the latest edition of AWS D1.1 and shall use E70XX electrodes.

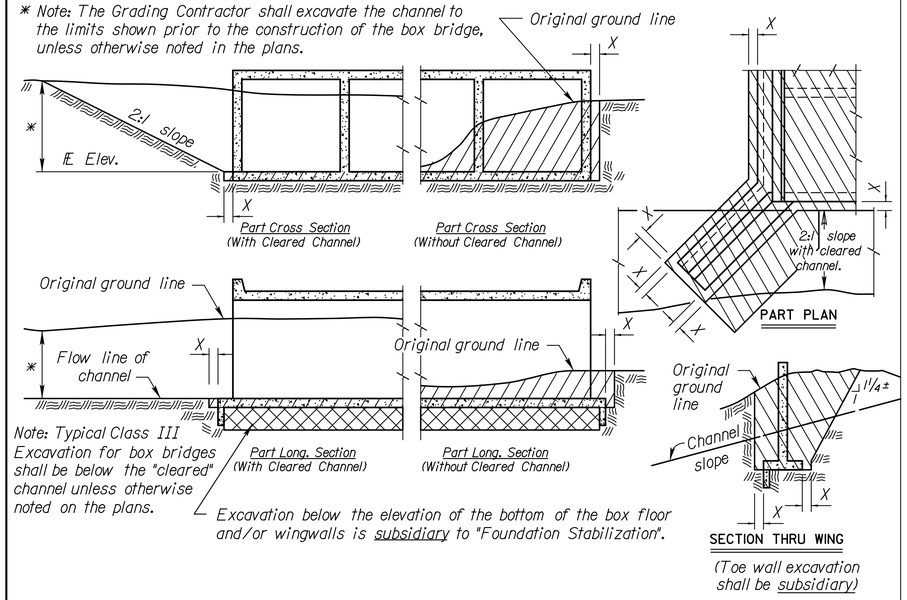
KANSAS	046 N-0576-01	2013	38	99

* Note: The Grading Contractor shall excavate the channel to the limits shown prior to the construction of the box bridge, unless otherwise noted in the plans.

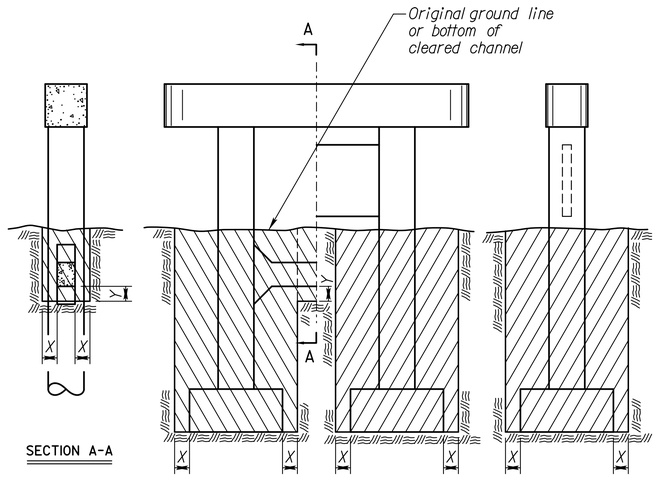


Note: Typical Class III Excavation for box bridges shall be below the "cleared" channel unless otherwise noted on the plans.

Excavation below the elevation of the bottom of the box floor and/or wingwalls is subsidiary to "Foundation Stabilization".

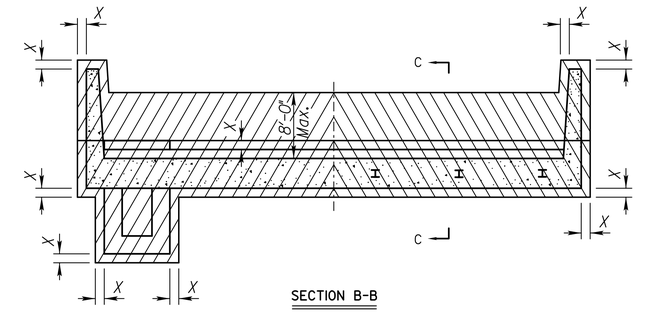
EXCAVATION DETAILS FOR REINFORCED CONCRETE BOX CULVERT

Note: Excavation for culverts less than bridge length and the additional excavation for "Embedded Structures" shall not be paid for as Class III Excavation, but shall be subsidiary to Grade 4.0 Concrete.



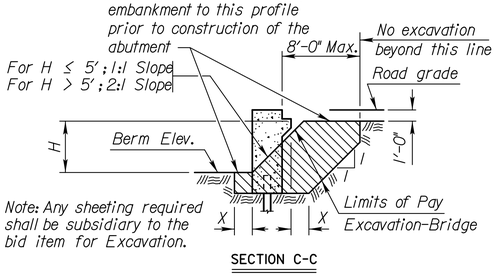
EXCAVATION DETAILS FOR TYPICAL PIERS

See detail when rock or shale (rock) is encountered. ⊛



Note: Bridge Contractor shall finish the embankment and berms after the construction of the abutment and dispose of any excess material as approved by the Engineer.

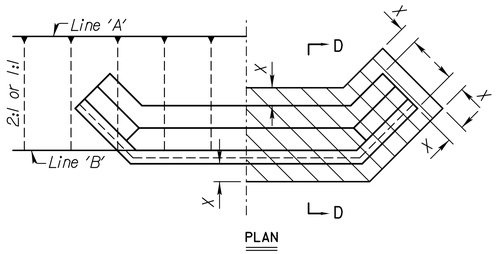
Grading Contractor to complete embankment to this profile prior to construction of the abutment

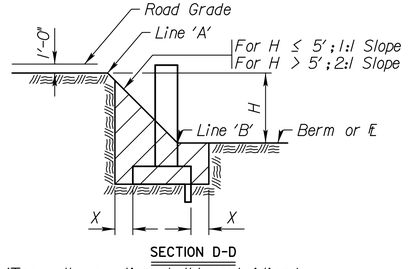


Note: Any sheeting required shall be subsidiary to the bid item for Excavation.

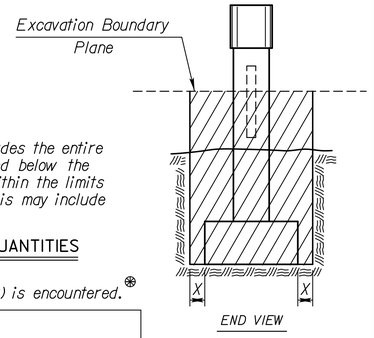
EXCAVATION DETAILS FOR TYPICAL ABUTMENTS

See detail when rock or shale (rock) is encountered. ⊛





EXCAVATION DETAILS FOR ABUTMENTS WITH FLARED WINGWALLS



Note: Class II Excavation includes the entire volume of whatever nature found below the "Excavation Boundary Plane", within the limits specified for measurement. This may include water or air.

CLASS II EXCAVATION QUANTITIES

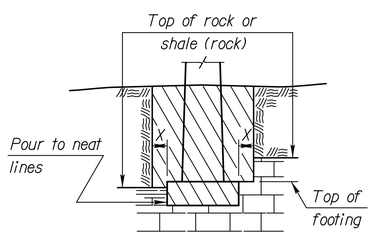
See detail when rock or shale (rock) is encountered. ⊛

Note: All bridge excavation shall be computed on the basis of the cross-hatch areas and boundary lines indicated on this sheet and the Excavation Boundary Plane on the Construction Layout.

Sides of trenches in hard or compacted soil including embankments shall be shored, sheeted, braced or otherwise supported when the trench is more than 5 feet in depth and 8 feet or more in length. In lieu of the shoring, the sides of the trench above the 5 foot level may be sloped to preclude collapse. The slope for average soils shall be 1:1. If the angle of repose of the soil is less, flatter slopes shall be required.

Dimension "X" shall be 2'-0" unless indicated otherwise on the general plans.

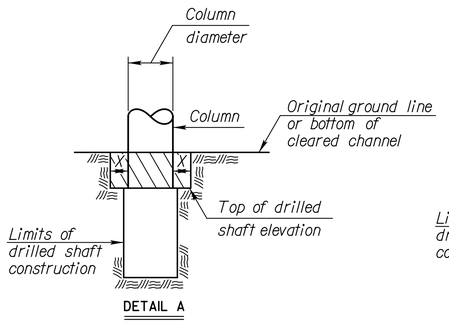
Dimension "Y" shall be 1'-6" unless indicated otherwise on the general plans.

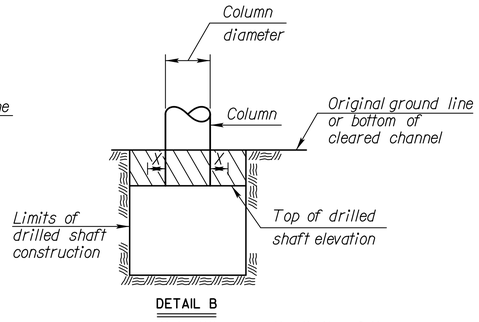


⊛ EXCAVATION DETAIL FOR FOOTINGS IN ROCK OR SHALE (ROCK)

(Piers and Abutments)

Note: Excavation below top of rock, hard shale or below top of footing, whichever is lower, shall be to neat lines of the concrete construction.





DRILLED SHAFT DETAILS

Note: Whenever the limits of the drilled shaft construction are greater than the Column Diameter + 2X, the limits of Class I, II or III Excavation shall be the limits of the drilled shaft construction. (See Detail B)

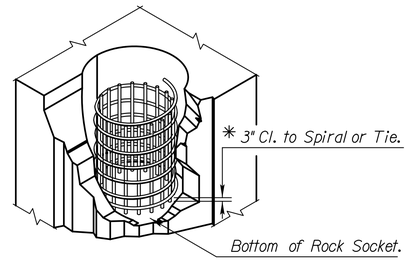
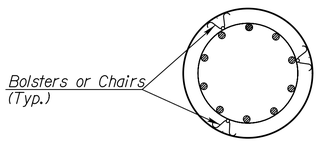
DRILLED SHAFT



DETAIL A

* Note: Longitudinal reinforcing steel is placed on the bottom of the rock socket. Maintain 3" clearance from the bottom of rock socket to the first spiral or tie bar.



SECTION A-A

TYPICAL SECTION

Reference is made to the latest edition of the CRSI "Manual of Standard Practice" for recommended industry practices concerning reinforcing steel.

Use only the following types of bar supports:

1) Wire Bar Supports:

a) Epoxy coated reinforcing: Class 1 Protection
b) Non-epoxy coated reinforcing: Class 1, 2, or 3 Protection

2) Plastic Bar Supports

3) Supplementary bars

When securing epoxy coated reinforcement, use tie wires or metal clips that are epoxy or plastic coated.

Do not weld reinforcing steel to bar supports or to other reinforcing steel. Shop weld spacer frames for haunched slabs.

Tie bars at all intersections around the perimeter of each mat and at not less than 2'-0" centers or at every intersection, whichever is greater.

Where more than one length of bar support is required, lap the end legs so they are locked or tied together.

Use proper height supports to maintain the distance between the reinforcing and the formed surface or the top surface of deck slabs within 1/4" of that indicated on the plans.

Spacings shown are maximums. Use sufficient supports, as determined by the Engineer, to retain the reinforcing steel in position.

Construct any platforms, required for the support of workers and/or equipment during concrete placement, directly on the forms and not on the reinforcing steel.

Designs and arrangements of Supports or Spacers other than as shown on this sheet, may be used with the permission of the Engineer.

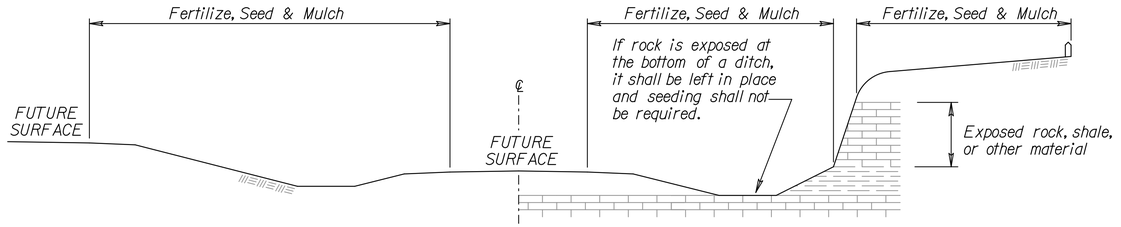
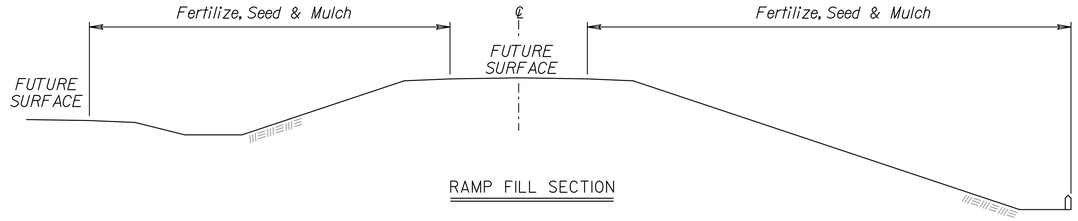
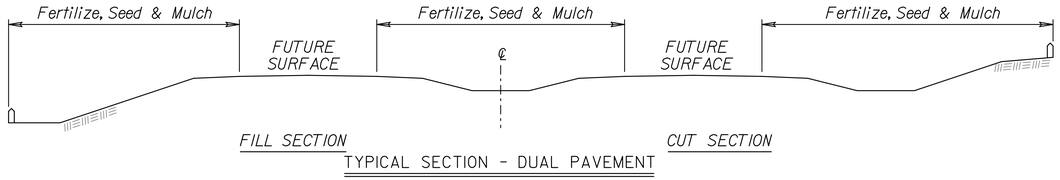
KANSAS	046 N-0576-01	2013	41	99



RAMP CUT SECTION



RAMP FILL SECTION



TYPICAL SECTION - DUAL PAVEMENT

FERTILIZER: A ratio and application rate that equals or exceeds the required minimum rate per acre of N, P_2O_5, K_2O listed in Summary of Quantities will be acceptable.

- *x - N = Nitrogen Rate of Application*
- *xx - P_2O_5 = Phosphorous Rate of Application*
- *xxx - K_2O = Potassium Rate of Application*

The Contractor will be required to finish areas of excavation, borrow and embankment in accordance with the specifications. Areas that require installation or construction of temporary water pollution control items will be finished in reasonable close conformity to the alignment, grade and cross section shown on the plans or as established by the Engineer.

CLT = Construction Limit Tract. This area is defined by the entire disturbed area of the project that requires seeding and erosion control measures to be placed. Any impervious areas (i.e. pavement, gravel, riprap, etc.) shall not be included in this measurement.

Slope = Defined by the area of the project that requires Class 1 erosion control material to be placed. This area shall be seeded using the Soil Erosion Mix prior to placement of the material. Broadcasting seed is preferred, however, drilling is acceptable.

Channel = Defined by the area of the project that requires Class 2 erosion control material to be placed. This area shall be seeded using the Soil Erosion Mix prior to placement of the material. Broadcasting seed is preferred, however, drilling is acceptable.

GENERAL NOTES

The entire disturbed area, excepting the paved or surfaced areas, steep rocky slopes and areas of undisturbed native sod or other desirable vegetation shall be fertilized (limed when required), seeded, and mulched. Soil preparation shall conform to the Standard Specifications.

Temporary seeding shall be done during any time of the year that the soil can be cultivated. After the temporary seeding has been completed on the entire project, a permanent seeding shall be done by another project during the normal seeding season.

MULCHING: Mulch shall be spread uniformly over all disturbed areas and punched in the soil, unless otherwise noted on the plans. The rate of application per acre, thickness in place, for the mulching materials is as follows:

1¾ - 2¼ Tons per Acre = 1½" loose depth spread uniformly over acre.

Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.
Other vegetative mulches acceptable only with the Engineer's concurrance.

The above rate is a guide. It will be at the discretion of the Engineer to determine what rate is sufficient for adequate protection of newly seeded areas.
The amount of mulch and mulch tacking slurry in the bid quantities is estimated. The total mulch and mulch tacking slurry required shall be determined in the field. The bid item for mulching and mulch tacking slurry shall be paid for by one of the following ways: A) Plan quantity as shown on Summary of Quantities, Seeding Sheet or Water Pollution Control Sheet, B) Slope measurement as measured in field, or C) Drill measurement less 5% as measured at the time of seeding.

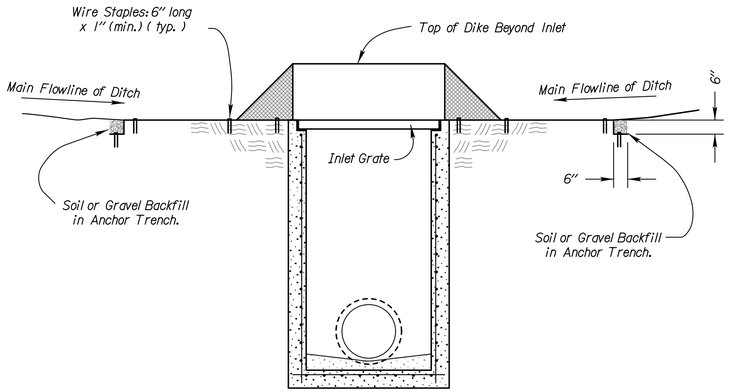
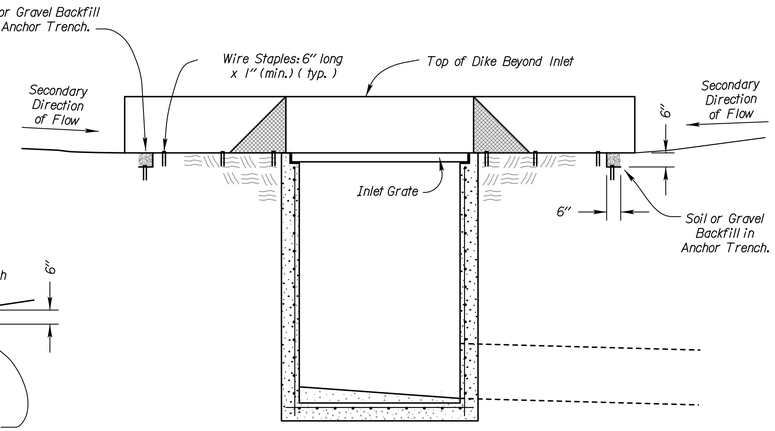
PLAN

TEMPORARY INLET SEDIMENT BARRIER
(TRIANGULAR SILT DIKE METHOD)

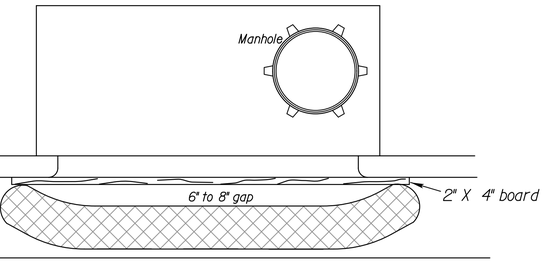
NO SCALE



SECTION A - A



SECTION B - B

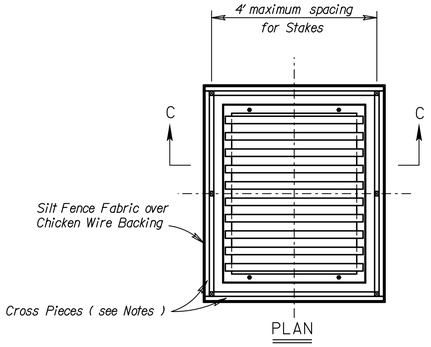


Bags = synthetic net (3mm mesh) or burlap bags

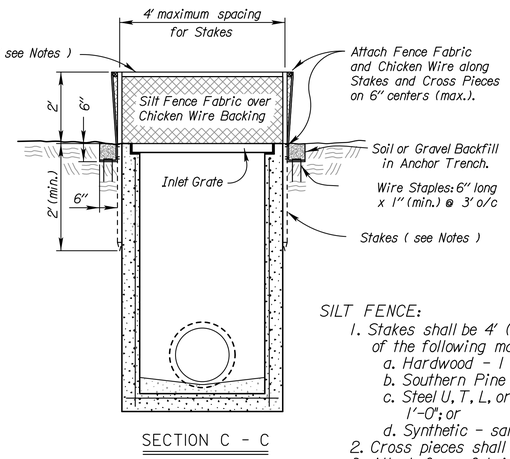
Rock = approximately 1" to 2" diameter

CURB INLET PROTECTION

1. If multiple gravel bags are required, place them in such a way that no gaps are evident.
2. Height of bags (8" minimum diameter) must not be above top of curb.
3. Alternative products may be used other than gravel bags such as the "Gutter Buddy". Products must be approved by the Engineer.
4. Curb inlet protection will be measured and paid for as Filter Sock.



PLAN



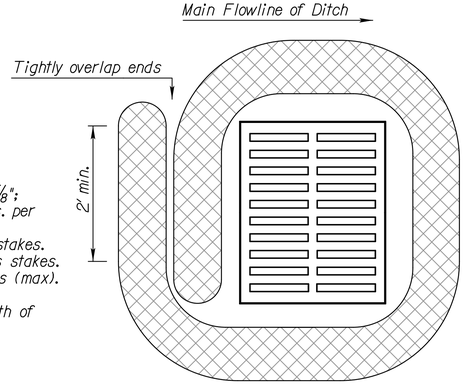
SECTION C - C

TEMPORARY INLET SEDIMENT BARRIER
(SILT FENCE METHOD)

NO SCALE

SILT FENCE:

1. Stakes shall be 4' (min.) long and of one of the following materials:
   a. Hardwood - 1 3/16" x 1 3/16";
   b. Southern Pine (No. 2) - 2 5/8" x 2 5/8";
   c. Steel U, T, L, or C Section - 1.25 lbs. per 1'-0"; or
   d. Synthetic - same strength as wood stakes.
2. Cross pieces shall be of same material as stakes.
3. Attach fence fabric securely on 6" centers (max).
4. Use of high flow material is acceptable.
5. Refer to plan sheets to estimate the length of silt fence required.



Drop inlet use
1'-6" TO 1'-8" diameter log

BIODEGRADABLE LOG/FILTER SOCK
DROP INLET PROTECTION

Note: 25% of log shall be keyed into ground during installation.

Stake every 4'

Material Requirements
Use 100% shredded mulch or other non-compost biodegradable material as fill for logs.
No compost or fines.
No hay or straw.
Do not use material which prohibits water infiltration.
Log Mesh: Use mesh with 1/4" openings or larger. Mesh must allow water infiltration but also hold fill materal in place.

GENERAL NOTES

1) The slope barriers shall be placed along contour lines, with a short section turned upgrade at each end of the barrier. The maximum length of the slope barrier shall not exceed 250 feet, and the barrier ends need to be staggered.
2) At culverts, the Silt Fence shall be placed over the culvert, not through the streambed flowline.
3) Barriers damaged by Contractor's negligence, including improper maintenance or lack of maintenance, shall be repaired immediately by Contractor at no additional cost to KDOT.
4) Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.

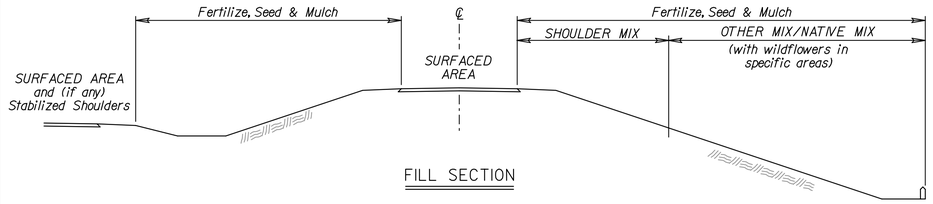
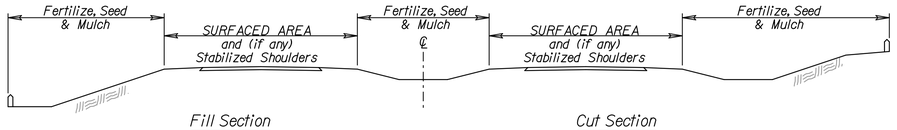
CUT SECTION



FILL SECTION



TYPICAL SECTION - DUAL PAVEMENT

SEEDING PERIODS

COOL SEASON February 15 to April 20 and August 15 to Sept. 30	WARM SEASON November 15 to June 1
SPECIES	SPECIES
Bluegrasses	Big Bluestem
Bromegrasses	Blue Grama
Canada Wildrye	Buffalograss
Fescues	Eastern Gamagrass
Prairie Junegrass	Indiangrass
Reed Canarygrass	Little Bluestem
Ryegrasses	Sand Bluestem
Sterile Wheatgrass	Sand Dropseed
Tall Dropseed	Sand Lovegrass
Western Wheatgrass	Side Oats Grama
	Switchgrass
	Wildflower Mixes

When "Cool Season" species are mixed with "Warm Season" species, in areas of 1 acre or more, the mixture shall be seeded during the "Warm Season". In areas of less than 1 acre, the mixture of "Cool Season" and "Warm Season" species may be seeded during the "Warm or Cool Seasons".

SODDING PERIODS
March 1 to April 15 and September 1 to November 15

GENERAL NOTES

The entire disturbed area, excepting the paved or surfaced areas, steep rocky slopes and areas of undisturbed native sod or other desirable vegetation shall be fertilized (limed when required), seeded, and mulched. Soil preparation shall conform to the Standard Specifications except as noted below.

All borrow areas shown on the plans are to be fertilized, seeded, and mulched. However, operation in borrow areas where crops are growing may be omitted when requested by the owner.

It shall not be required to till the area to bare ground prior to permanent seeding. If temporary cover has provided stable slopes with no erosion, seed the permanent grasses into the existing cover. If there has been erosion that requires repair prior to seeding, then it may be necessary to regrade the area, resulting in bare ground.

FERTILIZER: A ratio and application rate that equals or exceeds the required minimum rate per acre of N, P_2O_5, K_2O listed in Summary of Seeding Quantities will be acceptable.

MULCHING: Mulch shall be spread uniformly over all disturbed areas and punched in the soil, unless otherwise noted on the plans. The rate of application per acre, thickness in place, for the mulching material is as follows:

1¾ - 2¼ Tons per Acre = 1½" loose depth spread uniformly over acre.

Agricultural products, such as native prairie hay, used for mulching and erosion control practices, excluding wood based mulch, shall meet the North American Weed Free Forage Standards.

Other vegetative mulches are acceptable only with the Engineer's concurrence.

The above rate is a guide. It will be at the discretion of the Engineer to determine what rate is sufficient for adequate protection of newly seeded areas.

The amount of mulch in the quantities is estimated. The total mulch required shall be determined in the field. The bid item for mulching shall be paid for according to Standard Specification Section 904.

THE GENERAL NOTES:

THE GENERAL NOTES, REMOVAL NOTES AND NOTES ON THE PLAN SHEETS HAVE BEEN GENERALLY WRITTEN IN THE IMPERATIVE MOOD. THE SUBJECT ' THE CONTRACTOR' IS IMPLIED. ALSO IMPLIED IN THIS LANGUAGE ARE 'SHALL', 'SHALL BE', OR SIMILAR WORDS OR PHRASES. THE WORD 'WILL' GENERALLY PERTAINS TO DECISIONS OR ACTIONS OF THE KANSAS DEPARTMENT OF TRANSPORTATION (KDOT).

ALL WIRING AND WIRING METHODS SHALL COMPLY WITH THE MOST CURRENT NATIONAL ELECTRIC CODE STANDARDS, ANY CHANGES TO THESE STANDARDS SHALL BE APPROVED BY THE AUTHORITY HAVING JURISDICTION.

LOCATE ALL EXISTING UTILITES PRIOR TO BEGINNING WORK.

GROUND ALL METAL PARTS OF SWITCHES, CASES, POLES AND CONDUIT USED ABOVE GROUND WITH A NO. 6 BARE WIRE.

PROVIDE INSPECTION OF EACH TOWER BY A FACTORY REPRESENTATIVE OF THE RAISE AND LOWER DEVICE PRIOR TO FINAL ACCEPTANCE OF THE PROJECT BY THE KANSAS DEPARTMENT OF TRANSPORTATION.

MAKE SPLICES IN THE INDUCT SECONDARY CABLE INSIDE OF TOWER BASES, POLE BASES AND JUNCTION BOXES. CONTACT THE BUREAU OF TRANSPORTATION SAFETY & TECHNOLOGY FOR APPROVAL OF OTHER SPLICE LOCATIONS.

A REPRESENTATIVE FROM THE KANSAS DEPARTMENT OF TRANSPORTATION'S REGIONAL MATERIALS LAB WILL VISUALLY INSPECT ALL TOWERS AND COMPLETE A TEST REPORT PRIOR TO ASSEMBLY.

PROVIDE WELD PROCEDURE NUMBERS FOR THE DIFFERENT TYPES OF WELDS ON THE SHOP DRAWINGS FOR LIGHTING TOWERS. INCLUDE THE KDOT LAB NUMBER UNDER WHICH THESE WELD PROCEDURES HAVE BEEN APPROVED.

OZ EXPANSION JOINTS SHALL BE INSTALLED IN THE CONDUIT RUNS AT ALL BRIDGE EXPANSION JOINTS.

FURNISH AND INSTALL LIGHTING EQUIPMENT, INCLUDING TOWERS, CONCRETE BASES FOR TOWERS, ANCHOR BOLTS, LUMINAIRES, LAMPS, WIRING, CONDUIT, CONDUIT FITTINGS, SUPPORTS, INTERCONNECTIONS, GROUND RODS, AND ALL INCIDENTIALS NECCESSARY FOR THE COMPLETE INSTALLATION WITHIN THE LIMITS SHOWN ON THE PLANS. FURNISH AND INSTALL ALL EQUIPMENT NECESSARY FOR SATISFACTORY OPERATION, WHETHER SPECIFICALLY MENTIONED OR NOT.

PLOW OR TRENCH AND BACKFILL UNDERGROUND CONDUCTOR INDUCT APPROXIMATELY 2 FT. BELOW GROUNDLINE. BACKFILL IN ALL AREAS SHALL BE FREE OF RUBBLE AND ROCK.

FINAL LOCATION FOR ENCLOSURE INSTALLATION(S) IS/ARE TO BE DETERMINED BY THE ENGINEER IN CHARGE. POSITION THE ENCLOSURE(S) SO THAT THE PHOTOCELL(S) IS/ARE POINTED DUE NORTH.

THE FOLLOWING COMPANIES HAVE A RAISE AND LOWERING DEVICE THAT HAS BEEN ACCEPTED BY THE KANSAS DEPARTMENT OF TRANSPORTATION: AMERICAN HIGH MAST, EAGLE HIGH MAST LIGHTING CO., CAROLINA HIGH MAST, HOLOPHANE, METROLUX AND STRATUS. ADDITIONAL COMPANIES DESIRING APPROVAL BY THE KDOT MUST INSTALL ONE RAISE AND LOWERING DEVICE ON A POLE PROVIDED BY THE KDOT IN TOPEKA, OR ON ANOTHER POLE AS APPROVED. THE INSTALLATION WILL BE REVIEWED AND TESTED BY KDOT PRIOR TO APPROVAL ON THIS PROJECT. ALL ASSOCIATED COSTS WILL BE THE RESPONSIBILITY OF THE MANUFACTURERS/CONTRACTORS.

THE FOLLOWING COMPANIES HAVE SCREW-IN LIGHT POLE FOUNDATIONS THAT HAVE BEEN ACCEPTED BY THE KANSAS DEPARTMENT OF TRANSPORTATION : A.B. CHANCE COMPANY AND J.H. BOTTS, INC. ADDITIONAL COMPANIES DESIRING APPROVAL BY KDOT MUST SUBMIT DESIGN COMPUTATIONS AND CATALOG CUTS TO THE KANSAS DEPARTMENT OF TRANSPORTATION, BUREAU OF TRANSPORTATION SAFETY & TECHNOLOGY, EISENHOWER BUILDING, 700 SW HARRISON, 6TH FLOOR, TOPEKA, KS 66603-3754.

DUE TO SOIL CONDITIONS IN ALL OR PART OF THE FOLLOWING COUNTIES, SCREW-IN LIGHT POLE FOUNDATIONS MAY ONLY BE USED FOR ROADWAY LIGHTING UPON APPROVAL BY THE KANSAS DEPARTMENT OF TRANSPORTATION, BUREAU OF TRANSPORTATION SAFETY & TECHNOLOGY: BOURBON, CRAWFORD, CHEROKEE, LABETTE, MEADE, CLARK, COMANCHE, KIOWA, BARBER, HARPER, AND KINGMAN. SCREW-IN FOUNDATIONS SHALL NOT BE INSTALLED IN DISTRICT ONE.

ALL ATTACHMENTS TO BRIDGES SHALL HAVE A HIGHWAY RIGHT OF WAY PERMIT (DOT304) AND UTILITY ATTACHMENT PERMIT (DOT 310) APPROVED BEFORE WORK BEGINS, IN ACCORDANCE WITH CURRENT KANSAS DEPARTMENT OF TRANSPORTATION UTILITY ACCOMMODATION POLICY.

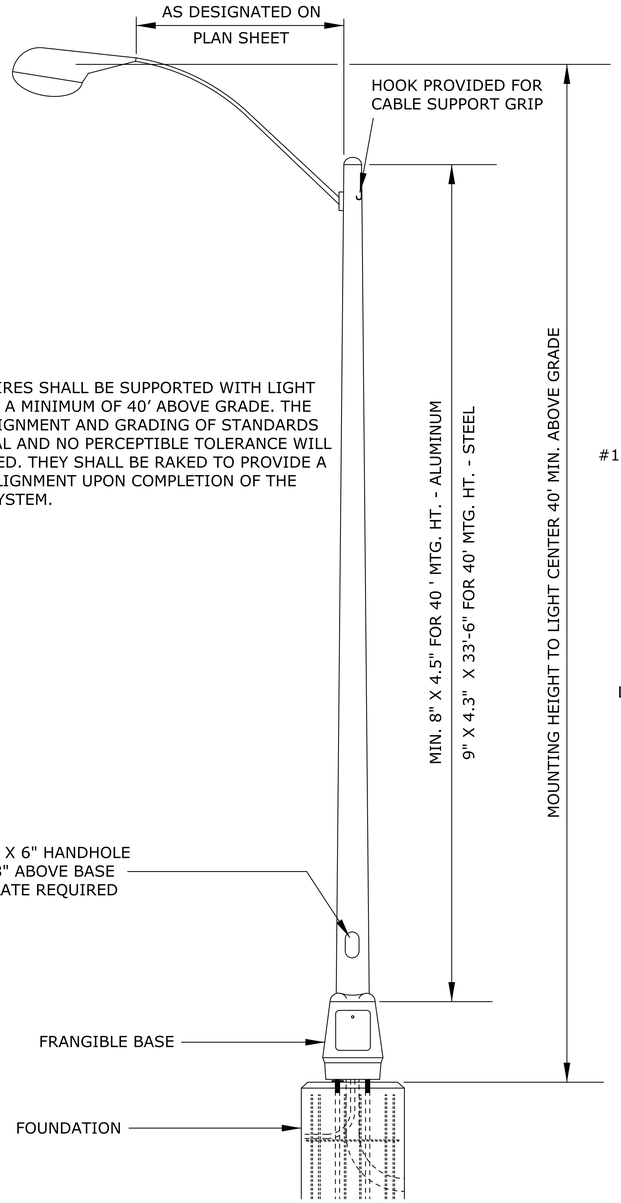
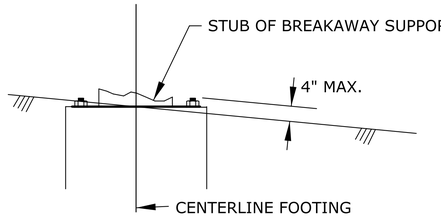
KANSAS	046 N-0576-01	2013	53	99

GROUNDING NOTE:
LIGHT STANDARDS SHALL BE GROUNDED BY MEANS OF A NO.6 AWG SOLID BARE COPPER GROUND WIRE BOLTED TO THE INSIDE OF THE LIGHT STANDARD SHAFT WITH A 1½" GROUNDING NUT. GROUND WIRE SHALL BE CONNECTED TO THE COPPERCLAD GROUND ROD BY MEANS OF A GROUND ROD CLAMP WITH AN EXOTHERMIC CONNECTION.



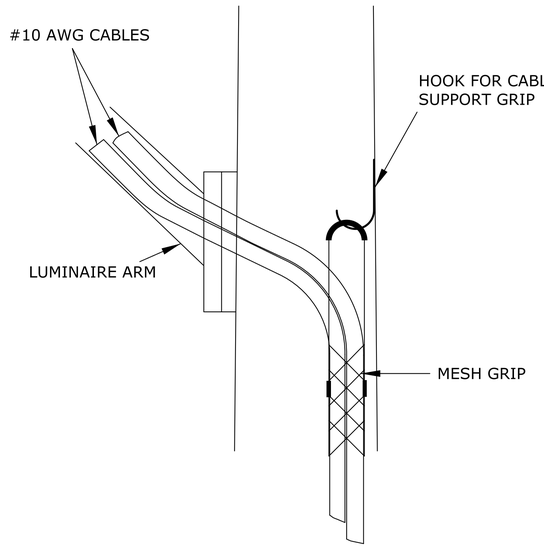
NOTE:
ALL LUMINAIRES SHALL BE SUPPORTED WITH LIGHT CENTERS AT A MINIMUM OF 40' ABOVE GRADE. THE CAREFUL ALIGNMENT AND GRADING OF STANDARDS IS ESSENTIAL AND NO PERCEPTIBLE TOLERANCE WILL BE PERMITTED. THEY SHALL BE RAKED TO PROVIDE A VERTICAL ALIGNMENT UPON COMPLETION OF THE LIGHTING SYSTEM.

THE 4" MAX. IS A REQUIREMENT OF THE BREAKAWAY CRITERIA IN THE LATEST EDITION OF AASHTO STANDARD SPECIFICATIONS FOR STRUCTURAL SUPPORTS FOR HIGHWAY SIGNS, LUMINAIRES AND TRAFFIC SIGNALS (NO. 12.5.3).



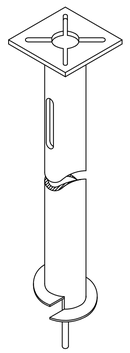
BREAKAWAY SUPPORT STUB CLEARANCE DIAGRAM

NOTE:
THE FOUNDATION SHALL BE INSTALLED TO MEET THE BREAKAWAY SUPPORT STUB CLEARANCE OF 4" MAXIMUM, TO INCLUDE ANCHOR BOLTS.



CABLE SUPPORT GRIP

NOTE:
THE CABLE SUPPORT GRIP SHALL BE INSTALLED ON THE HOOK SUPPLIED WITHIN THE LIGHT POLE AS SHOWN ABOVE.



SCREW-IN BASE

NOTE:
DUE TO SOIL CONDITIONS IN ALL OR PART OF THE FOLLOWING COUNTIES, SCREW-IN LIGHT POLE FOUNDATIONS MAY ONLY BE USED FOR ROADWAY LIGHTING UPON APPROVAL BY THE KANSAS DEPARTMENT OF TRANSPORTATION BUREAU OF TRANSPORTATION SAFETY & TECHNOLOGY: BOURBON, CRAWFORD, CHEROKEE, LABETTE, MEADE, CLARK, COMANCHE, KIOWA, BARBER, HARPER, AND KINGMAN. SCREW-IN FOUNDATIONS SHALL NOT BE INSTALLED IN DISTRICT ONE.

File : te201.dgn

STATE	PROJECT NO.	YEAR	SHEET NO.	TOTAL SHEETS
KANSAS	046 N-0576-01	2013	54	99

NOTE:
WHENEVER THE PLAN SPECIFICATIONS CONFLICT WITH THE STANDARD KANSAS DEPARTMENT OF TRANSPORTATION SPECIFICATIONS, LATEST EDITION, THE PLAN SPECIFICATIONS SHALL GOVERN.

CONSTRUCTION:
LIGHT STANDARDS SHALL BE DESIGNED TO COMPLY WITH THE 2009 EDITION OF THE AASHTO PUBLICATION, STANDARD SPECIFICATIONS FOR STRUCTURAL SUPPORTS FOR THE HIGHWAY SIGNS, LUMINAIRES, TRAFFIC SIGNALS, AND CURRENT INTERIMS. USE FATIGUE CATEGORY II. SEE STANDARD SPECIFICATIONS, LATEST EDITION, SECTION 814.

LIGHT STANDARDS:
(A) STEEL STANDARDS: THE LIGHT STANDARDS SHALL COMPLY WITH THE REQUIREMENTS OF ASTM 607 WITH THE EXCEPTIONS AND/OR ADDITIONS AS LISTED IN THE STANDARD KANSAS DEPARTMENT OF TRANSPORTATION SPECIFICATIONS, LATEST EDITION, SECTION 1608.2. THE LIGHT STANDARDS WITH 40' MOUNTING SHALL BE ONE (1) SECTION. THE DIAMETER OF THE STANDARDS SHALL BE SHOWN ON THE DETAIL SHEETS.

(a) BASE: THE BASE SHALL BE EITHER A ONE (1) PIECE STEEL BASE COMPLYING WITH THE REQUIREMENTS OF ASTM A-27, GRADE 65-35, A STEEL FORGED BASE COMPLYING WITH THE REQUIREMENTS OF ASTM A-668, CLASS C OR A PLATE BASE COMPLYING WITH THE REQUIREMENTS OF ASTM A 36-77A. THE BASE SHALL BE SECURED TO THE BOTTOM SECTION BY TWO (2) CONTINUOUS ELECTRIC ARC WELDS.

(b) MAST ARMS: THE MAST ARMS SHALL BE FABRICATED FROM 2" STANDARD PIPE MEETING THE REQUIREMENTS OF ASTM A-53 OR ASTM A-35.

(c) FINISH: THE BASE, MAST ARMS, AND LIGHT STANDARDS SHALL BE GALVANIZED ACCORDING TO ASTM A-123.

(B) ALUMINUM STANDARDS: STANDARDS SHALL CONFORM TO THE PLAN DRAWINGS AND SPECIFICATIONS. THE SHAFT SHALL BE SPUN FROM ONE PIECE OF SEAMLESS TUBING (ASTM B-429) ALUMINUM ASSOCIATION ALLOY 6063-T6, WITH MINIMUM NOMINAL WALL THICKNESS OF 0.312 INCH FOR 40' MOUNTING HEIGHT. AFTER FABRICATION IT SHALL HAVE MECHANICAL STRENGTH OF NOT LESS THAN T6 TEMPER. THE SHAFT SHALL HAVE NO LONGITUDINAL NOR CIRCUMFERENTIAL WELDS EXCEPT AT THE LOWER END JOINING THE SHAFT TO THE BASE.

(a) BASE: A ONE-PIECE CAST ALUMINUM (ASTM B-108 ALLOY S.G. 70A-T6) ANCHOR BASE OF ADEQUATE STRENGTH, SHAPE AND SIZE BE SECURED TO THE LOWER END OF THE SHAFT BY TWO (2) CONTINUOUS WELDS. THE BASE SHALL TELESCOPE THE SHAFT AND THE ONE WELD SHALL BE ON THE INSIDE OF THE BASE AT THE END OF THE SHAFT WHILE THE OTHER WELD SHALL BE ON THE OUTSIDE AT THE TOP OF THE BASE. (THE TWO (2) WELDS SHALL DEVELOP THE DESIGN STRENGTH OF THE POLE ASSEMBLY.)

(b) MAST ARMS: SINGLE MEMBER TYPE: THE BRACKET ARM ASSEMBLY SHALL CONSIST OF A TAPERED ALUMINUM ARM, ELLIPTICAL IN SHAPE AT THE POLE END AND TAPERING TO A MINIMUM OF 2 1/4" O.D. AT THE LUMINAIRE END, MADE OF (ASTM B-429) ALUMINUM ASSOCIATION ALLOY 6063-T6 TUBING.

TRUSS TYPE MEMBER: THE UPPER AND LOWER MEMBERS SHALL BE 2" IPS ALUMINUM PIPE, (ASTM B-429) ALUMINUM ASSOCIATION ALLOY 6063-T6.

(c) FINISH: ALL HARDWARE (BOLTS, NUTS, AND WASHERS - BUT NOT INCLUDING ANCHOR BOLTS) NOT OTHERWISE SPECIFICALLY DESIGNATED IN THE SPECIFICATIONS, SHALL BE ALUMINUM OR STAINLESS STEEL. ALL MATERIALS SHALL BE FURNISHED IN NATURAL ALUMINUM COLOR, POLE SHAFTS SHALL BE FURNISHED WITH A POLISHED SURFACE.

ELECTRICAL MATERIAL:

(A) PHOTO CELL: PHOTO-ELECTRIC CONTROL SHALL BE SOLID STATE TYPE, 1000 W/1800 VA, SINGLE POLE, SINGLE THROW, TWIST LOCK MOUNTING, 105 TO 300 VOLT OPERATION. THE OPERATING LEVELS SHALL BE 1.6 FT. C. ON AND 0.4 FT. C. OFF, WITH AN ALLOWABLE 0.5 FT. C. VARIANCE ON OR OFF. THE PHOTO-ELECTRIC CONTROL SHALL HAVE A MINIMUM OF 30 SECOND TIME DELAY AND FAIL IN THE ON MODE.

(B) DUCT: THE DUCT FOR SECONDARY CABLE UNDERGROUND SHALL BE POLYETHYLENE DUCT WITH MINIMUM TENSILE STRENGTH OF 3100 PSI DUCT TO PROVIDE FOR 40% MAXIMUM FILL. THE DUCT SIZED SHALL MEET ASTM D3485 (LATEST REVISION).

(C) CONDUCTOR: CONDUCTOR SHALL BE STRANDED ANNEALED COPPER MEETING THE REQUIREMENTS OF ASTM B-8 AND ASTM B-33.

(a) SECONDARY CABLE (INDUCT): SECONDARY CABLE SHALL BE COPPER SINGLE CONDUCTOR CABLE FOR OPERATION AT 600 VOLTS MAXIMUM. MATERIAL SHALL MEET THE APPLICABLE REQUIREMENTS OF ICEA STANDARD S-105-692 AND LISTED BY UL AS TYPE USE-2 FOR DIRECT BURIAL.

(D) LUMINAIRES: ALL LUMINAIRES SHALL BE SUPPLIED WITH HIGH POWER FACTOR BALLAST.

150 WATT LUMINAIRES: 150 WATT LUMINAIRES SHALL HAVE A HOUSING OF ALUMINUM ALLOY CASTING WITH AN INTEGRAL SLIPFITTER FOR A 2 INCH BRACKET MOUNTING WITH A NATURAL UNPAINTED ALZAK ALUMINUM REFLECTOR. THE BALLASTS SHALL BE A VOLTAGE AUTO-REGULATOR TYPE FOR HIGH PRESSURE SODIUM AT A VOLTAGE OF 480 VOLTS. THE REFRACTORS SHALL BE ACRYLIC WITH TYPE III LIGHT DISTRIBUTION.

(E) SODIUM LUMINAIRE IGNITORS: ALL HPS LUMINAIRES SHALL BE EQUIPPED WITH THE FOLLOWING:

HIGH PRESSURE SODIUM IGNITORS: ELECTRONIC IGNITOR FOR THE IGNITION OF HIGH PRESSURE SODIUM (HPS) VAPOR LAMPS. THE IGNITOR SHALL BE DESIGNED TO DIRECT THE HIGH VOLTAGE SPIKE DIRECTLY TO THE LAMP WITHOUT BEING DIRECTED TO THE LAMP THROUGH THE BALLAST WINDINGS. THE IGNITOR SHALL BE CAPABLE OF BEING USED WITH ALL BRANDS AND TYPES OF 60 HERTZ HPS BRANDS. THE IGNITOR SHALL BE DESIGNED SO THAT CYCLING OR EXTINGUISHED LAMP SHALL NOT ADVERSELY AFFECT THE IGNITOR OR BALLAST. THE IGNITOR SHALL BE BE TOTALLY EPOXY ENCAPSULATED IN A METAL CAN AND SHALL BE OPEN CIRCUIT TESTED FOR A PERIOD OF 48 HOURS WITH POWER APPLIED AT ELEVATED TEMPERATURES TO 100°C WITH CONSTANT MONITORING OF CASE TEMPERATURES. THE IGNITOR SHALL HAVE A TWO (2) MINUTE TIME DELAY. IF THE LAMP DOES NOT START, THE IGNITOR WILL BE SHUT OFF UNTIL THE POWER TO THE LUMINAIRES IS RESET BY THE PHOTO CONTROL. THE IGNITOR SHALL BE WARRANTED AGAINST DEFECTIVE MATERIALS AND WORKMANSHIP FOR A PERIOD OF NOT LESS THAN FIVE (5) YEARS FROM THE SHIPPING DATE.

(F) LAMPS: (a) 150 WATT LAMPS: 150 WATT LAMPS SHALL BE 16,000 LUMEN, HIGH PRESSURE SODIUM.

(G) ENCLOSURE: THE ENCLOSURE CABINET SHALL BE CONSTRUCTED OF 5052 ALLOY ALUMINUM 0.125" THICK. THE CABINET SHALL BE OF CLEAN CUT DESIGN HAVING NO SHARP EDGES, CORNERS OR PROJECTIONS. THE CIRCUITING SHALL BE SERVICEABLE BY MEANS OF A FULL LENGTH HINGED DOOR WITH PADLOCK PROVISIONS. THE ENCLOSURE SHALL HAVE 600 VOLT RATED MOLDED CASE MAIN AND SECONDARY BREAKERS, TWIST-LOCK PHOTO-CELL SOCKET, AND ELECTRICALLY HELD CONTACTORS. THE EQUIPMENT WITHIN THE ENCLOSURE SHALL BE WIRED PRIOR TO DELIVERY. THE ENCLOSURE SHALL HAVE A METER VIEW WINDOW AND A GLASS TO ALLOW LIGHT TO THE PHOTO-CELL.

(a) MAIN AND SECONDARY BREAKERS: THE MAIN AND SECONDARY BREAKERS SHALL HAVE A MOUNTING DIMENSIONS OF 1 3/8" WIDE X 4 1/2" HIGH MOUNTING HOLES SHALL BE POSITIONED TO ACCOMMODATE A BREAKER 2 3/4" WIDE SIDE BY SIDE. SEE ENCLOSURE DETAIL SHEET.

GENERAL MATERIALS AND NOTES:

(A) MISCELLANEOUS HARDWARE: MISCELLANEOUS HARDWARE THAT REQUIRES GALVANIZING OR ELECTROPLATING SHALL CONFORM TO THE STANDARD KANSAS DEPARTMENT OF TRANSPORTATION SPECIFICATIONS, LATEST EDITION, SECTION 1703.2 (c).

(B) METALLIC CONDUIT: METALLIC CONDUIT SHALL BE RIGID STEEL CONDUIT MEETING THE REQUIREMENTS OF AMERICAN STANDARD SPECIFICATION C-80.1. TRENCHING FOR CONDUIT WILL NOT BE PERMITTED THROUGH EXISTING PAVEMENT. JACKING WILL NOT BE PERMITTED IN DISTRICT ONE UNLESS APPROVED BY THE ENGINEER IN CHARGE OF CONSTRUCTION.

(C) METALLIC CONDUIT FITTINGS: METALLIC CONDUIT FITTINGS SHALL BE ZINC COATED AND SHALL MEET THE REQUIREMENTS OF AMERICAN STANDARD SPECIFICATION C-80.1.

(D) NON-METALLIC CONDUIT: D.1 RIGID POLYVINYL CHLORIDE MEETING THE REQUIREMENTS OF FEDERAL SPECIFICATIONS NO. LP 1036A, TYPE II, ELECTRICAL CLASS 2, GRADE C. EACH LENGTH SHALL BEAR THE UNDERWRITERS, INC. LABEL. NON-METALLIC CONDUIT FITTINGS SHALL BE FABRICATED FROM POLYVINYL CHLORIDE HAVING THE SAME CHEMICAL AND PHYSICAL PROPERITIES AS THE CONDUIT WITH WHICH IT IS TO BE USED. EACH SHALL BEAR THE UNDERWRITERS, INC. LABEL. THE JOINTS SHALL BE MADE IN ACCORDANCE WITH THE MANUFACTURERS RECOMMENDATIONS.

D.2. HIGH DENSITY POLYETHYLENE (HDPE) MEETING THE REQUIREMENTS OF ASTM F 2160 AND ASTM F 2176. A LETTER OF CERTIFICATION (LOC) WILL BE REQUIRED FROM THE CONDUIT PRODUCER AND/OR RESIN PRODUCER. THE CONDUIT WILL NEED TO BE MARKED WITH ASTM F 2160 DESIGNATION ON THE PRINT LINE.

(E) GROUND: GROUND WIRE SHALL BE A #6 AWG SOLID BARE COPPER WIRE AND ARRANGEMENT SHALL BE AS NOTED ON PLANS.

(F) ANCHOR BOLTS: ANCHOR BOLTS SHALL CONFORM TO THE STANDARD KANSAS DEPARTMENT OF TRANSPORTATION SPECIFICATIONS, LATEST EDITION, SECTION 1600 (GRADE 55), WITH THE FOLLOWING EXCEPTION. DO NOT USE CUT THREADS, USE ROLLED THREADS.

(G) BREAK-AWAY CABLE CONNECTORS: THE CONNECTORS SHALL PROVIDE A FUSED WATERPROOF WIRING CONNECTION THAT WHEN SUBJECTED TO STRAIN CONSISTANT WITH A KNOCKDOWN WILL SEPARATE WITHOUT DAMAGE TO WIRING. WHEN SEPARATION OCCURS, THE CONNECTORS SHALL HAVE NO CONTACTS EXPOSED TO PRESENT A SHOCK HAZARD. THE CABLE CONNECTORS SHALL MEET AASHTO STANDARD SPECIFICATIONS FOR STRUCTURAL SUPPORTS FOR HIGHWAY SIGNS, LUMINAIRES AND TRAFFIC SIGNALS (LATEST EDITION), ARTICLE 12.5.3 (C). CONNECTOR INSTALLATION SHALL BE AS DIRECTED BY THE MANUFACTURER.

(H) FRANGIBLE BASE: FRANGIBLE BASE SHALL BE CAST ALUMINUM TO MEET THE STANDARDS OF THE LATEST AASHTO STANDARD SPECIFICATIONS FOR STRUCTURAL SUPPORTS FOR HIGHWAY SIGNS, AND TRAFFIC SIGNALS. THE FRANGIBLE BASE SHALL ACCOMMODATE UP TO A 15" BOTTOM BOLT CIRCLE. THE FRANGIBLE BASE SHALL HAVE HIGH DENSITY PLASTIC DOORS. THE COLOR SHALL BE PIGMENTED THROUGHOUT TO GIVE THE APPEARANCE OF ALUMINUM. THE DOORS SHALL WITHSTAND TEMPERATURE EXTREMES OF -70° TO 150° F. AND ARE COMPOUNDED WITH U.V. INHIBITORS.

(I) JUNCTION BOXES (IN-GROUND): THE JUNCTION BOX SHALL BE OF SUFFICIENT SIZE TO FACILITATE THE CONDUIT AND WIRING AS INDICATED IN THE PLANS. JUNCTION BOXES SHALL HAVE THE MINIMUM NOMINAL DIMENSIONS OF 12 INCHES DEEP WITH A MINIMUM PHYSICAL OPENING OF 130 SQUARE INCHES. IN-GROUND JUNCTION BOXES MAY BE CONSTRUCTED OF ONE OF THE FOLLOWING METHODS:

PRE-CAST CONCRETE WITH A CAST IRON COVER; POLYMER CONCRETE WITH A POLYMER CONCRETE COVER; FIBERGLASS REINFORCED POLYMER BODY WITH A POLYMER CONCRETE RING AND COVER; HIGH DENSITY POLYETHYLENE BODY WITH POLYMER CONCRETE RING AND COVER. THE RING SHALL BE SECURELY ATTACHED TO THE BODY.

ENCLOSURES, BOXES AND COVERS ARE REQUIRED TO CONFORM TO ALL TEST PROVISIONS OF ANSI/SCTE 77 2002 "SPECIFICATION FOR UNDERGROUND INTEGRITY" FOR TIER 15 APPLICATIONS.

THE COVER SHALL BEAR THE LOGO "LIGHTING" CLEARLY AND PERMANENTLY MOLDED OR ETCHED INTO THE COVER.

JUNCTION BOXES (ABOVE-GROUND): ABOVE GROUND JUNCTION BOXES SHALL HAVE THE NOMINAL DIMENSIONS OF 12 INCHES BY 12 INCHES BY 6 INCHES. THE JUNCTION BOX SHALL BE MADE OF 14 GAUGE SHEET METAL(STEEL) WITH WELDED SEAMS, KNOCKOUTS AND WEATHER PROOF SCREW COVER. BOXES SHALL BE HOT DIPPED GALVANIZED IN ACCORDANCE WITH ASTM A-123 AFTER FABRICATION.

(J) WEDGE TYPE STUD BOLT ANCHORS: THE CONTRACTOR SHALL INSTALL TWO 3/8" X 3" WEDGE TYPE ANCHORS FOR CONDUIT CLAMPS. THE ANCHORS SHALL BE WEDGE TYPE MADE FROM CARBON STEEL MEETING AISI 12L14 STEEL. THE MINIMUM EMBEDDED DEPTH SHALL BE 1 3/4".

(K) CONDUIT CLAMPS WITH CLAMP BACKS: THE CONTRACTOR SHALL INSTALL 2" CONDUIT CLAMPS WITH A COMPATIBLE CLAMP BACK. CLAMPS SHALL BE HEAVY DUTY STEEL TO SECURE THE 2" RIGID CONDUIT TO STRUCTURE. CONDUIT CLAMPS ARE TO BE SPACED AT 6' INTERVALS.

(L) CABLE GRIP SUPPORTS: THE CONTRACTOR SHALL INSTALL ONE (1) CABLE SUPPORT GRIP IN EACH ROADWAY LIGHTING POLE. THE CABLE SUPPORT GRIP SHALL BE MADE OF HIGH GRADE, NON-MAGNETIC TIN COATED BRONZE STRAND. THE CABLE SUPPORT GRIP SHALL BE CAPABLE OF SECURING TWO (2) #10 AWG TYPE USE-2 CABLES IN A VERTICAL POSITION HOLDING THE WEIGHT OF THE CABLES AND CABLE CONNECTORS OFF THE LUMINAIRE ASSEMBLY. SEE ROADWAY LIGHTING DETAILS SHEET.

(M) ALL WELDS SHALL BE SMOOTH CLEAN DENSE DEPOSIT THAT WILL EXCLUDE MOISTURE AND CONFORM TO A.W.S. SPECIFICATION D1.1 (LATEST REVISION). FIELD WELDS WILL NOT BE ALLOWED.

(N) GROUND RODS SHALL BE COPPER CLAD STEEL, 3/4" DIAMETER BY 10' LONG.

THE FOLLOWING COMPANIES HAVE A RAISE AND LOWERING DEVICE THAT HAS BEEN ACCEPTED BY THE KANSAS DEPARTMENT OF TRANSPORTATION : AMERICAN HIGH MAST, EAGLE HIGH MAST LIGHTING CO., CAROLINA HIGH MAST, METROLUX AND HALOPHANE. ADDITIONAL COMPANIES DESIRING APPROVAL BY THE KDOT MUST INSTALL ONE RAISE AND LOWERING DEVISE ON A POLE PROVIDED BY THE KDOT IN TOPEKA, OR ON ANOTHER POLE AS APPROVED. THE INSTALLATION WILL BE REVIEWED AND TESTED BY KDOT PRIOR TO APPROVAL ON THIS PROJECT. ALL ASSOCIATED COSTS WILL BE THE RESPONSIBILITY OF THE MANUFACTURERS/CONTRACTORS.

✳ EACH TOWER SHALL BE INSPECTED BY A FACTORY REPRESENTATIVE OF THE RAISE AND LOWER DEVICE MANUFACTURER PRIOR TO FINAL ACCEPTANCE OF THE PROJECT BY THE KANSAS DEPARTMENT OF TRANSPORTATION.

NOTE: LINEAR QUANTITIES ARE APPROXIMATE AND INCLUDED FOR INFORMATION ONLY. THE CONTRACTOR SHALL CONDUCT ALL WORK, AND FURNISH AND INSTALL ALL EQUIPMENT NECESSARY, TO INSURE COMPLETE AND SATISFACTORY OPERATION OF THE ELECTRIC LIGHTING SYSTEM WHETHER SPECIFICALLY MENTIONED OR NOT.

- TYPE 3 OBJECT MARKER

GENERAL NOTES

IN ORDER TO EXPEDITE THE COMPLETION OF THE PROJECT FOR TRAFFIC SERVICE, THE SIGNING AND DELINEATOR WORK SHALL BE SEQUENCED WITH ANY OTHER CONTRACT WORK SUCH THAT THE PHASES OF CONSTRUCTION MAY PROCEED AND BE COMPLETED AT THE SAME TIME.

NEW SIGNS ERECTED ON THE PROJECT WHICH ARE IN CONFLICT WITH EXISTING SIGNING ARE TO BE COMPLETELY COVERED UNTIL THE EXISTING SIGNS ARE REMOVED OR THE NEW SIGNING IS APPLICABLE. THE EXISTING SIGNS THAT ARE BEING REPLACED, REMOVED, OR DO NOT FOLLOW THE CURRENT MUTCD SIGNING STANDARDS ARE TO BE REMOVED WHEN THE PROJECT IS COMPLETED OR AS DETERMINED BY THE ENGINEER.

THE CONTRACTOR SHALL EXERCISE CAUTION AT ALL TIMES WHEN INSTALLING SIGN SUPPORTS IN AND AROUND AREAS WHERE UTILITIES EXIST, EITHER UNDERGROUND OR OVERHEAD, AND WILL BE HELD RESPONSIBLE FOR ANY DAMAGE INCURRED TO THE SYSTEM. THE INSTALLATION OF SIGN SUPPORTS SHALL INCLUDE THE EXCAVATION, DRILLING, OR DRIVING THE SUPPORT FOOTING AND THE ERECTION OF THE SIGN SUPPORT. THE CONTRACTOR SHALL EXERCISE CAUTION WHEN WORKING AROUND ANY EXISTING SIGNS THAT ARE TO REMAIN AND WILL BE HELD RESPONSIBLE FOR ANY DAMAGE TO THE SIGNS, SUPPORTS, OR FOOTINGS. THE CONTRACTOR SHALL EXERCISE CARE WHEN WORKING AROUND SHRUBBERY WHILE REMOVING OR INSTALLING SIGNS OR SIGN SUPPORTS.

AN EXISTING SIGN POST INSTALLATION SHALL BE PLUMB AND THE COMPACTION OF THE BACKFILL SOIL SHALL COMPLY WITH THE SPECIFICATIONS AFTER THE REMOVAL AND RESETTING OF A SIGN, THE REMOVAL AND REPLACEMENT OF A SIGN, OR THE INSTALLATION OF A NEW SIGN.

THE CONTRACTOR SHALL PROVIDE MOUNTING BOLTS THAT ARE OF A LENGTH THAT DOES NOT EXTEND MORE THAN A NOMINAL 1 INCH BEYOND THE SIGN POST. THE CONTRACTOR SHALL NOT MAKE ANY FIELD MODIFICATIONS TO THE MOUNTING BOLT PRIOR TO OR AFTER THE SIGN IS INSTALLED.

SPECIFIC SERVICE, LOGO, SIGNS THAT ARE TO BE REMOVED SHALL HAVE THE BUSINESS LOGO PLAQUES REMOVED AND TRANSPORTED TO LOCATION DETERMINED BY KDOT, AT WHICH TIME THE PLAQUES BECOME THE PROPERTY OF KDOT. THE CONTRACTOR WILL BE ASSESSED A REPLACEMENT COST FOR ANY DAMAGE TO A BUSINESS LOGO PLAQUE PRIOR TO THE PLAQUE BECOMING THE PROPERTY OF KDOT.

THE MATERIALS AND FABRICATION FOR SIGNING AND DELINEATION WORK SHALL CONFORM TO THE STANDARD SPECIFICATIONS FOR STATE ROAD AND BRIDGE CONSTRUCTION (2007 EDITION) AND SPECIAL PROVISIONS.

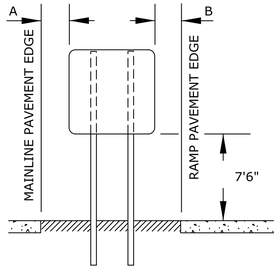
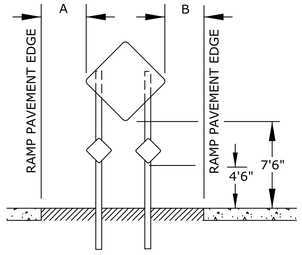
(DIMENSIONS ARE MINIMUMS)



GORE INSTALLED SIGN
(MAINLINE/RAMP)



GORE INSTALLED SIGN
WITH TWO T1/OM'S
(RAMP/RAMP)

NOTES:
THE OUTER EDGE OF THE SIGN, ON EXPRESSWAYS AND FREEWAYS, SHALL BE A MINIMUM OF 10 FEET FROM THE RIGHT OF WAY LINE.
IN BUSINESS, COMMERCIAL, OR RESIDENTIAL DISTRICTS WHERE LATERAL OFFSETS ARE LIMITED, A MINIMUM LATERAL CLEARANCE OF 2 FEET WITH A 7'6" MINIMUM MOUNTING HEIGHT MAY BE USED.
WHEN SIGNS ARE MOUNTED BEHIND GUARD FENCE, THE NEAR EDGE OF THE SIGN SHALL NOT EXTEND BEYOND THE BACK SIDE OF THE GUARD FENCE AND THE NEAREST SIGN POST SHALL BE A MINIMUM OF 5 FEET FROM THE FACE OF THE GUARD FENCE. THERE SHALL NOT BE ANY SHOULDER MOUNTED SIGNS LOCATED BETWEEN 100 FEET IN ADVANCE OF AND 50 FEET BEYOND THE NOSE OF THE GUARD FENCE.
WHEN SIGNS ARE MOUNTED IN A MEDIAN, THE LATERAL PLACEMENT SHOULD BE THE SAME AS A SHOULDER MOUNT. IF THE MEDIAN IS TOO NARROW FOR THIS PLACEMENT THE SIGN MAY BE PLACED A MINIMUM OF 2 FEET FROM THE BACK OF THE CURB, BUT IN NO CASE SHALL THE SIGN EDGE EXTEND BEYOND THE BACK EDGE OF THE CURB. SIGNS LOCATED AT THE MEDIAN NOSE SHOULD BE SET THE SAME DISTANCE FROM THE BACK OF THE CURB AS THE RADIUS OF THE MEDIA NOSE, BUT SHOULD NOT EXCEED THE DISTANCE OF THE SHOULDER MOUNT OR BE CLOSER THAN 2 FEET FROM THE BACK OF THE CURB.

THE GORE SIGN SHALL BE INSTALLED IN THE FOOTING BLOCKOUT IN THE PAVED GORE AREA. IF NO BLOCKOUT IS PROVIDED, THEN LOCATE THE GORE SIGN AT THE PLAN STATION. THE EDGES OF THE GORE SIGN SHALL NOT EXTEND BEYOND THE SHOULDER EDGE. THE MINIMUM DISTANCE FROM THE POST CENTERLINE TO THE BACK EDGE OF THE PAVED GORE AREA IS 3 FEET.

ADJUSTMENTS:
SIGNS MAY BE MOVED LATERALLY OR LONGITUDINALLY IF IT WILL IMPROVE THE VISIBILITY OF THE SIGN OR OTHER SIGNS AND IF IT WILL PROTECT THE SIGN MORE.
THE MAXIMUM ALLOWABLE LONGITUDINAL ADJUSTMENTS OF SIGNS ARE:
ADVANCE GUIDE - 1320 FEET
SUPPLEMENTAL GUIDE - 1320 FEET
MOTORIST SERVICE - 1320 FEET
EXIT DIRECTION - 100 FEET
MILEAGE - 2640 FEET
MERGE OR ANY SIGNS IN AN INTERCHANGE - 50 FEET
MILEPOST - 50 FEET
IF ANY SIGN WITH A DISTANCE IS LONGITUDINALLY ADJUSTED, THE DISTANCE TO THE DESTINATION SHALL BE CHECKED AND MODIFIED AS NEEDED.
THE MINIMUM SPACING BETWEEN GUIDE SIGNS ON AN EXPRESSWAY OR FREEWAY IS 800 FEET.
THE MINIMUM SPACING BETWEEN SIGNS ON A RAMP OR CONVENTIONAL ROADWAY IS 100 FEET.

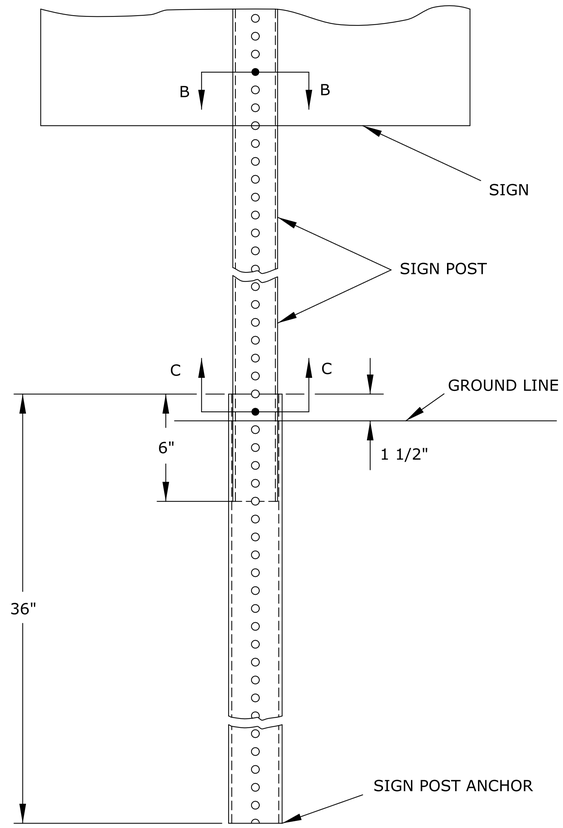
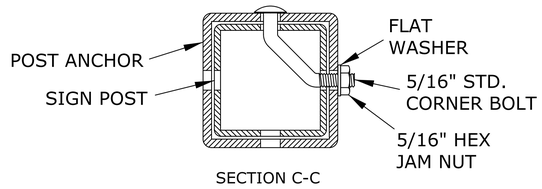
DETAILS FOR 1 3/4", 2", OR 2 1/4" SIGN POST





DETAILS FOR 2 1/2" SIGN POST

MATERIAL REQUIREMENTS

SIGN POSTS, POST ANCHORS, AND POST ANCHOR SLEEVES:
THE SIGN POSTS, POST ANCHORS, AND POST ANCHOR SLEEVES SHALL CONFORM TO (1) HOT ROLLED CARBON STEEL ASTM A-570 GRADE 33 OR ASTM STRUCTURAL QUALITY C 1021 WITH A HOT-DIPPED GALVANIZING CONFORMING TO AASHTO M-120 WITH AN INLINE SYSTEM FOLLOWED BY A CHROMATE CONVERSION AND A CROSS-LINKED POLYURETHANE ACRYLIC EXTERIOR COATING OR (2) A GALVANIZED FINISH COLD ROLLED CARBON STEEL ASTM A-446 GRADE A WITH A GALVANIZING CONFORMING TO ASTM A-525, DESIGNATION G-90.

THE SIGN POST SHALL HAVE 7/16" DIA. HOLES OR 7/16" DIA. EMBOSSED RING (DIE-CUT KNOCKOUTS) AT 1" CENTERS ON ALL FOUR SIDES FOR TOTAL LENGTH OF POST.

THE POST ANCHOR AND POST ANCHOR SLEEVE MAY BE FURNISHED WITHOUT THE BOLT HOLES ON ALL FOUR SIDES WITH THE EXCEPTION OF THE HOLES IMMEDIATELY ABOVE THE GROUND LINE.

ALL HOLES SHALL BE DRILLED OR PUNCHED AND ALL WELDS, CUTS, BURRS, AND SHARP EDGES ARE TO BE SMOOTHED OFF BEFORE APPLICATION OF FINISH.

FASTENING ACCESSORIES:
THE BOLTS, NUTS, AND WASHERS SHALL COMPLY WITH SUBSECTION 1614 OF THE STANDARD SPECIFICATIONS FOR STATE ROAD AND BRIDGE CONSTRUCTION (1990 EDITION).

THE BOLTS, NUTS, AND WASHERS SHALL BE BID SUBSIDIARY TO THE BID ITEM 'SQUARE STEEL POST'.

BASIS OF ACCEPTANCE:
ACCEPTANCE OF THE STEEL POSTS, ANCHORS, SLEEVES, AND FASTENERS FURNISHED TO COMPLY WITH THE ABOVE REQUIREMENTS WILL BE BASED ON RECEIPT AND APPROVAL OF A TYPE D CERTIFICATION AS DESCRIBED IN SECTION 2600 OF THE STANDARD SPECIFICATIONS FOR STATE ROAD AND BRIDGE CONSTRUCTION (1990 EDITION) AND VISUAL INSPECTION FOR CONDITION AND DIMENSIONAL REQUIREMENTS.

INSTALLATION SEQUENCE

1. DRIVE POST ANCHOR INTO SUBGRADE.
2. DRIVE POST ANCHOR SLEEVE (IF REQUIRED) INTO SUBGRADE OVER THE POST ANCHOR.
3. INSTALL SIGN POST INTO THE POST ANCHOR.

NOTE:
IN ALL INSTALLATIONS, THE FIRST HOLE ABOVE THE GROUND LINE ON THE SIGN POST, POST ANCHOR, AND POST ANCHOR SLEEVE (IF REQUIRED) MUST BE IN LINE FOR INSERTION OF THE CORNER BOLT.

MATERIALS TABLE FOR SIGN POST AND FOOTING		
SIGN POST 12 GA. OR 14 GA.	FOOTING	
	POST ANCHOR	POST ANCHOR SLEEVE
1 3/4 " X 1 3/4 "	2" X 2" X 12 GA.	2 1/4" X 2 1/4" X 12 GA.
2" X 2"	2 1/4" X 2 1/4" X 12 GA.	2 1/2" X 2 1/2" X 12 GA.
2 1/4" X 2 1/4"	2 1/2" X 2 1/2" X 12 GA.	3" X 3" X 7 GA.
2 1/2" X 2 1/2"	3" X 3" X 7 GA.	NOT REQUIRED

NOTE: 14 GA. POSTS MUST MEET A CERTIFIED MINIMUM YIELD STRENGTH OF 60,000 P.S.I.

DETAILED SPECIFICATIONS FOR FLAT SHEET SIGNS

ALL NEW FLAT SHEET SIGN BLANKS SHALL BE OF THE ALUMINUM ALLOY AND THICKNESS SHOWN ON THE FLAT SHEET BLANK DETAIL SHEETS.

FLAT SHEET BLANKS SHALL BE USED FOR SIGNS THAT ARE LESS THAN OR EQUAL TO 7'-0" IN LENGTH AND/OR LESS THAN OR EQUAL TO 4'-0" IN HEIGHT. FLAT SHEET BLANKS SHALL ALSO BE USED FOR SIGNS THAT ARE 4'-0" IN LENGTH AND LESS THAN OR EQUAL TO 8'-0" IN HEIGHT.

THE DESIGN DETAILS FOR SIGNS (COLOR, LETTER HEIGHT, AND LETTER SERIES) SHALL BE AS SHOWN IN THE 'STANDARD HIGHWAY SIGNS' MANUAL (2004 EDITION), UNLESS OTHER DETAILS ARE SHOWN IN THE PLANS.

ALL SIGN FACES WITH BLUE, GREEN, RED, YELLOW, FLUORESCENT YELLOW GREEN, BROWN, OR WHITE BACKGROUND SHALL BE COVERED WITH TYPE IV HIGH INTENSITY RETROREFLECTIVE SHEETING.

THE TYPE OF ADHESIVE USED FOR RETROREFLECTIVE SHEETING OR LETTERING FILM SHALL BE HEAT ACTIVATED OR PRESSURE SENSITIVE.

THE SIGN FACES SHALL BE DIRECT SCREEN PROCESS, REVERSE SCREEN PROCESS, OR DIRECT APPLIED LEGEND.

DETAILED SPECIFICATIONS FOR STRUCTURAL EXTRUDED PANEL SIGNS

ALL NEW REINFORCED SIGN PANELS SHALL BE OF THE FABRICATION, ALUMINUM ALLOY, AND THICKNESS SHOWN ON THE REINFORCED PANEL DETAIL SHEETS. IF EXTRUSHEET FABRICATED SIGN PANELS ARE USED, THEY SHALL BE OF THE LENGTH, WIDTH AND IN THE POSITION SHOWN. IF EXTRUSHEET FABRICATED PANEL DIMENSIONS ARE NOT SHOWN, A LINE OF LEGEND SHOULD BE PLACED ENTIRELY ON ONE PANEL. IF EXTRUDED FABRICATED SIGN PANELS ARE USED, EITHER 1'-0" OR 6" PANELS SHALL BE USED. THE 1'-0" PANELS SHALL BE USED ONLY AT THE TOP OR BOTTOM OF SIGNS.

REINFORCED PANELS SHALL BE USED FOR SIGNS THAT ARE GREATER THAN 7'-0" IN LENGTH OR GREATER THAN 4'-0" IN HEIGHT.

ALL SIGN FACES SHALL BE COVERED WITH TYPE IV HIGH INTENSITY RETROREFLECTIVE SHEETING.

THE RETROREFLECTIVE SHEETING USED FOR THE DIRECT APPLIED LEGEND, AND DIRECT APPLIED BORDERS SHALL BE TYPE IV HIGH INTENSITY RETROREFLECTIVE SHEETING.

THE TYPE OF ADHESIVE USED FOR RETROREFLECTIVE SHEETING OR LETTERING FILM SHALL BE HEAT ACTIVATED OR PRESSURE SENSITIVE.

LETTERS AND NUMBERS ON REINFORCED PANEL SIGNS ARE MODIFIED SERIES "E" UNLESS OTHERWISE SHOWN.

SPACING TABLE DIMENSIONS ARE IN INCHES.

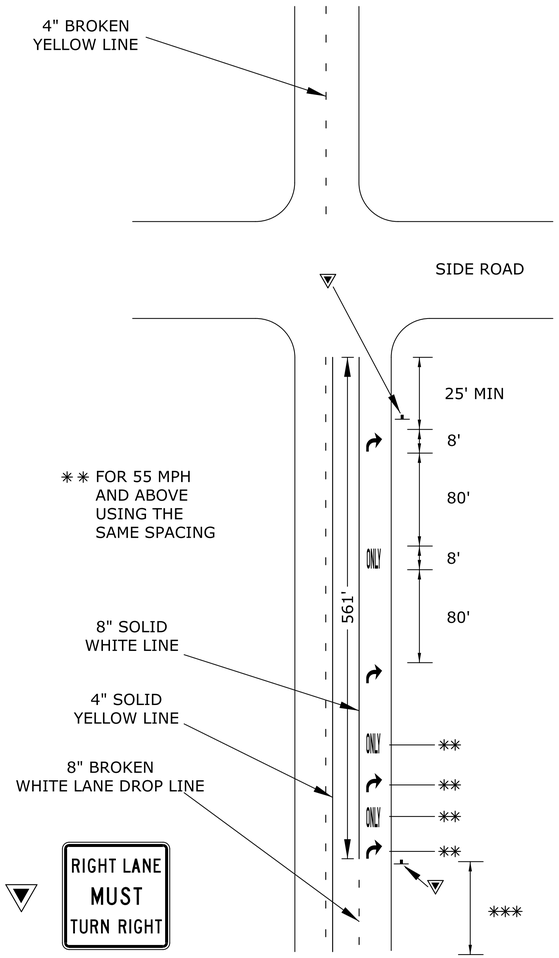
TYPICAL SIGNING AND MARKING FOR RIGHT LANE MUST TURN RIGHT



✳✳ FOR 55 MPH AND ABOVE USING THE SAME SPACING

✳✳✳ THE LANE DROP MARKINGS LENGTH IS A MINIMUM OF 100' AND A MAXIMUM OF 250' PRIOR TO THE 8"SOLID WHITE LINE

RAILROAD CROSSING MARKING

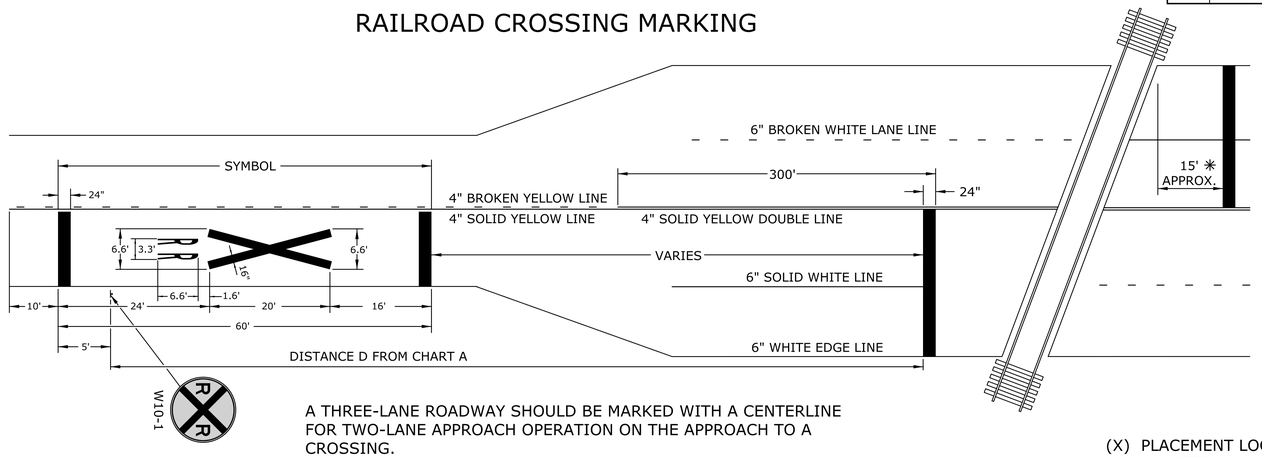


CHART "A"

SPEED MPH	DISTANCE D (feet)
75	850
70	750
65	650
60	550
55	450
50	375
45	300
40	225
35	150
30	(X)
25	(X)
20	(X)

ALL DISTANCES ARE MINIMUM.

A THREE-LANE ROADWAY SHOULD BE MARKED WITH A CENTERLINE FOR TWO-LANE APPROACH OPERATION ON THE APPROACH TO A CROSSING.
ON MULTI-LANE ROADS THE TRANSVERSE BANDS SHOULD EXTEND ACROSS ALL APPROACH LANES, AND INDIVIDUAL R X R SYMBOLS SHOULD BE USED IN EACH APPROACH LANE.
REFER TO STANDARD ALPHABET FOR HIGHWAY SIGNS AND MARKINGS FOR R X R SYMBOLS DETAILS.

*STOP LINE 8' FROM NEAR EDGE OF GATE OR CANTILEVER, IF PRESENT.

NOTE:
ON NON I, US, AND K ROUTES, 4" EDGE LINES MAY BE INSTALLED.
6" EDGE LINES ARE NOT REQUIRED ON NON I, US, AND K ROUTES.

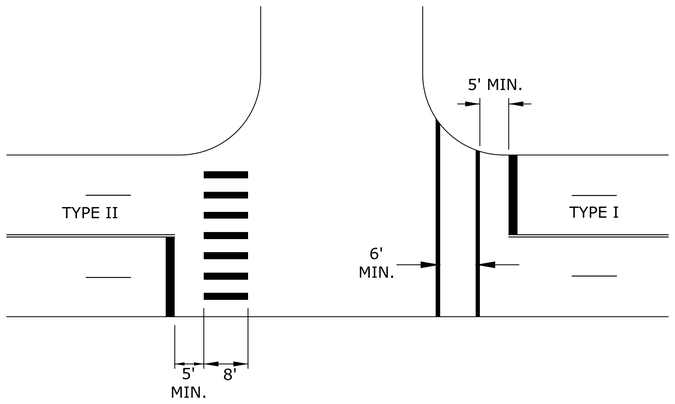
(X) PLACEMENT LOCATION IS DEPENDENT ON SITE CONDITIONS AND OTHER SIGNING TO PROVIDE ADEQUATE ADVANCE WARNING TO THE DRIVER

TYPICAL CROSSWALKS

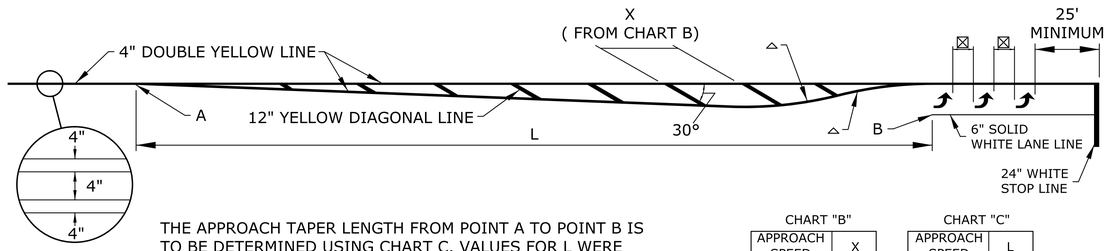
TYPE I: CROSSWALK LINES SHALL BE 12" SOLID WHITE LINES. THEY SHALL BE SPACED A MINIMUM OF 6' APART FROM INSIDE EDGE TO INSIDE EDGE.

TYPE II: THESE LINES SHOULD BE SOLID WHITE 24" WIDE PLACED PARALLEL TO THE DIRECTION OF TRAFFIC FLOW. THE LINE PLACEMENT IS DETERMINED BY LANE LINE,CENTER LINE, AND WHEEL PATH IN SUCH A MANNER AS TO MINIMIZE TRAFFIC WEAR. THE CROSSWALK WIDTH SHOULD BE NOT LESS THAN 8'. THE TRANSVERSE CROSSWALK LINES MAY BE ADDED.

WHEN REQUIRED, STOP LINES SHALL BE INSTALLED A MINIMUM OF 5' FROM CROSSWALKS.



TYPICAL APPROACH TAPER DETAIL



THE APPROACH TAPER LENGTH FROM POINT A TO POINT B IS TO BE DETERMINED USING CHART C. VALUES FOR L WERE CALCULATED USING THE EQUATIONS BELOW AND INCREASED TO THE NEXT HIGHER 5 MPH INCREMENT.

- SPEEDS < 45 MPH $L = \frac{W*S^2}{60}$
- SPEEDS = 45 MPH $L = W*S$

IF ARROWS ARE USED AND UNLESS OTHERWISE SPECIFIED THE SPACE BETWEEN LINES SHOULD BE AT LEAST FOUR TIMES THE HEIGHT OF THE CHARACTERS FOR LOW SPEED ROADS BUT NOT MORE THAN TEN TIMES THE HEIGHT OF THE CHARACTERS, UNDER ANY CONDITIONS.

FOR SPEEDS LESS THAN OR EQUAL TO 40 MPH, R=150'.
FOR SPEEDS GREATER THAN OR EQUAL TO 45 MPH, R=300'.

STATE	PROJECT NO.	YEAR	SHEET NO.	TOTAL SHEETS
KANSAS	046 N-0576-01	2013	72	99

GENERAL NOTE:

~~On surfacing~~ projects, the 6" of Compaction Type AA, shown for the center ~~portion~~ on the roadbed, ~~is for the purpose~~ of restoring the original ~~Compaction~~ Type AA which may have been lost since grading operations. ~~The exact~~ locations of this Compaction Type AA, which will be required, ~~is to be~~ determined by the ~~Engineer at the~~ time of construction. ~~This work shall~~ be paid under the bid item "Compaction of Earthwork (Type AA) (MR-)".

~~Over all structures~~, unless otherwise directed by the Engineer, ~~where the top of~~ the hubguard is ~~level with or above the finished shoulder grade~~, the earth cover over the structure ~~slab shall be removed and backfilled with~~ material ~~as directed by the Engineer~~. The removal of this material will be subsidiary.

~~The~~ material used to ~~backfill over the structure shall be paid for at the prices shown in the contract.~~

The earth shoulders shall be compacted full depth (Type -MR) except, when ordered by the Engineer, the top 3" shall be left uncompacted for seeding.

All side roads and house entrances shall be surfaced with to the R/W line as indicated on the detail. All side roads and house entrances with existing asphalt surface shall be surfaced with at least to the R/W line or to the end of construction, as directed by the Engineer. Each mailbox turnout (ON PROJECTS WHERE STABILIZED SHOULDERS ARE NOT SPECIFIED) shall be surfaced with to the limits shown on the detail.

Surfacing material (SA-) shall be used for surfacing house entrances and side roads (C.Y./SQ. YD.) beyond the limits of the asphalt surface to the limits of construction as determined by the Engineer.

~~The thickness~~ of side road and entrance surfacing may be ~~increased to the same thickness as the stabilized shoulder within the approximate limits of the shoulder.~~

On projects which specify both ~~asphalt base and~~ surface course materials, side roads, ~~house entrances~~ and mailbox turnouts may be ~~surfaced with~~ both materials ~~at the~~ contractors option, with the approval of the Engineer.

~~Quantities for aggregate for shoulders, AS-1, are calculated on the basis of 150 lbs. per cu. ft. Quantities for stabilized base course, AB-3, are calculated on the basis of 156 lbs. per cu. ft. Weight/cu. ft. includes moisture allowed by specification.~~

~~The base course shall be constructed to the plan thickness as shown.~~

Thicknesses indicated for all construction which is paid for on a weight or volume basis are approximate and may vary to correct for unevenness in the foundations or for other normal unevenness encountered in placement operations.

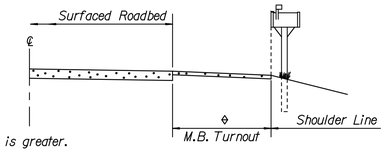
~~A tack coat of SS-1HP shall be provided between each lift of all base courses and surface courses and under the first lift of base or surface courses when they are placed on an existing asphalt, brick, or concrete surface, when so ordered by the Engineer and at the rate designated by him. Quantities are included for these tacks calculated at the rate of 0.05 gal./sq. yd.~~

~~Asphalt Material quantities are calculated on the basis of 8.328 lbs. per gal.~~

~~Shoulder rumble strips will not be constructed as part of this project.~~

HMA Commercial Grade (Class A)					
Location	*Station to Station*		*Thickness (in.)*	*Tons*	*Remarks*
Johnson Drive	*52+36.75*	*52+52.66*	*12"*	*9.5*	*S.W. Corner Bridge*
Johnson Drive	*52+45.85*	*52+52.66*	*12"*	*1.0*	*N.W. Corner Bridge*
			Total=	*10.5*	

Asphalt Unit weight used for calculation = 145 lb/cu.ft.
HMA quantity includes an additional 3/8" for contingency.



◊ *Width shall be 8' or shoulder width, whichever is greater.*

SECTION A-A

Note: The face of Mail Box should be no closer to the roadway than the edge of the shoulder. Align with edge of turnout when turnout width is greater than shoulder width.

TYPICAL PROFILE AT GRADE CONTROL POINTS

The Contractor shall cut the subgrade in accordance with this profile at all grade control points, i.e.; existing pavements, grade bridges and R.R. crossings, also at changes in thickness of base or surface courses. Corresponding dimensions of "D" and "L" shall be as given in the table below.

The work of cutting the subgrade and disposing of excess excavated material shall be subsidiary to other items in the contract.

KANSAS DEPARTMENT OF TRANSPORTATION

TRAFFIC CONTROL
SIDEWALK DETOUR
SEQUENCE 2

STATE	PROJECT NO.	YEAR	SHEET NO.	TOTAL SHEETS
KANSAS	046 N-0576-01	2013	80	99

1. MUTCD COMPLIANCE:

ALL TEMPORARY TRAFFIC CONTROL DEVICES AND THEIR INSTALLATION AND MAINTENANCE SHALL COMPLY WITH THE LATEST EDITION OF THE MANUAL ON UNIFORM TRAFFIC CONTROL DEVICES (MUTCD) FOR STREETS AND HIGHWAYS WHICH HAS BEEN ADOPTED BY THE SECRETARY OF TRANSPORTATION. WHENEVER THE TEMPORARY TRAFFIC CONTROL STANDARDS CONFLICT WITH THE MUTCD, THE STANDARDS SHALL GOVERN.

2. DESIGN SPEED:

THOSE ITEMS DELEGATED TO TEMPORARY TRAFFIC CONTROL SHOULD BE DESIGNED AND INSTALLED USING THE POSTED/LEGAL SPEED OF THE ROADWAY PRIOR TO WORK STARTING.

3. CLEAR ZONE:

ALL CONSTRUCTION EQUIPMENT (INCLUDING VEHICLES), MATERIALS, AND DEBRIS SHALL BE STORED OUT OF THE CLEAR ZONE. WHERE THIS CANNOT BE ACHIEVED, THE CONTRACTOR SHALL PLACE APPROPRIATE SIGNS, OBJECT IDENTIFIERS, AND/OR BARRICADES AS DESIGNATED BY THE ENGINEER. TEMPORARY TRAFFIC CONTROL DEVICES NEEDED FOR THIS CONDITION SHALL BE CONSIDERED SUBSIDIARY TO OTHER BID ITEMS.

4. MINIMUM LANE WIDTHS:

LANE WIDTHS SHALL BE A MINIMUM OF 11' (MEASURED BETWEEN CENTERLINES OF PAVEMENT MARKINGS) OR AS SHOWN ON THE PLANS, OR AS DIRECTED BY THE ENGINEER. A LANE WIDTH LESS THAN 11' MAY REQUIRE RESTRICTED ROADWAY WIDTH SIGNING.

5. FLAGGER:

A MINIMUM OF ONE FLAGGER SHALL BE STATIONED WITHIN EACH MULTI-LANE ROADWAY ACTIVITY AREA WHERE WORK IS IN A CLOSED LANE ADJACENT TO TRAFFIC AND NOT SEPARATED BY A CONCRETE SAFETY BARRIER SYSTEM.

6. PAVEMENT MARKING:

WHEN THE WORK WILL OCCUPY A LOCATION MORE THAN THREE DAYS, ALL CONFLICTING PAVEMENT MARKINGS SHALL BE REMOVED OR MASKED AND ALL TRANSITION TAPERS, CROSSOVERS, AND EDGE LINES ALONG CHANNELIZING DEVICES SHALL BE MARKED WITH SOLID 4" WIDE PAVEMENT MARKING.

7. FIRST MODULE OF IBS:

THE FIRST MODULE OF EACH INERTIAL BARRIER SYSTEM (IBS) SHALL HAVE A MINIMUM OF 2 SQ. FT. OF FLUORESCENT ORANGE ASTM TYPE IV SHEETING FACING TRAFFIC. EITHER A VERTICAL RECTANGLE OR DIAMOND SHAPE MAY BE USED.

8. PEDESTRIAN / BICYCLE SAFETY:

WORK ZONE SIGNS SHALL NOT INHIBIT PEDESTRIAN AND BICYCLE TRAFFIC ON SIDEWALKS OR OTHER AREAS DESIGNATED FOR PEDESTRIAN OR BICYCLE USE.

CONSIDERATION SHOULD BE MADE TO SEPARATE PEDESTRIAN AND BICYCLE MOVEMENTS FROM BOTH WORK SITE ACTIVITY AND VEHICULAR TRAFFIC. UNLESS A REASONABLE SAFE ROUTE THAT DOES NOT INVOLVE CROSSING THE ROADWAY CAN BE PROVIDED, PEDESTRIANS AND BICYCLISTS SHOULD BE APPROPRIATELY DIRECTED WITH ADVANCE SIGNING THAT ENCOURAGES THEM TO CROSS TO THE OPPOSITE SIDE OF THE ROADWAY. IN URBAN AND SUBURBAN AREAS WITH HIGH VEHICULAR TRAFFIC VOLUMES, THESE SIGNS SHOULD BE PLACED AT INTERSECTIONS (RATHER THAN MIDBLOCK LOCATIONS) SO THAT PEDESTRIANS AND BICYCLISTS ARE NOT CONFRONTED WITH MIDBLOCK WORK SITES THAT WILL INDUCE THEM TO ATTEMPT SKIRTING THE WORK SITE OR MAKING A MIDBLOCK CROSSING.

WHEN EXISTING PEDESTRIAN FACILITIES ARE DISRUPTED, CLOSED, OR RELOCATED, THE TEMPORARY FACILITIES SHALL BE DETECTABLE AND INCLUDE ACCESSIBILITY FEATURES CONSISTENT WITH THE FEATURES PRESENT IN THE EXISTING PEDESTRIAN FACILITY.

9. CHANGED STOP CONDITIONS:

ATTACH TWO FLUORESCENT RED-ORANGE FLAGS AND A RED TYPE "B" HIGH INTENSITY WARNING LIGHT TO ANY STOP SIGN THAT CREATES A NEW STOP CONDITION OR MOVES THE STOP CONDITION TO A NEW LOCATION. LEAVE FLAGS AND LIGHTS IN PLACE FOR AT LEAST THE FIRST 30 DAYS. INSTALL W3-1 (SYMBOLIC STOP AHEAD) SIGN IN ADVANCE OF STOP SIGN IF STOP SIGN IS NOT VISIBLE FOR A MINIMUM OF DISTANCE 'A' (SEE CHART ON TE710) OR IF STOP CONDITION IS MOVED TO LESS THAN DISTANCE 'A' FROM AN EXISTING STOP AHEAD SIGN.

10. LUMP SUM BIDDING:

WHEN TRAFFIC CONTROL IS BID LUMP SUM, ADDITIONAL DEVICES WILL BE PAID FOR AS EXTRA WORK.

11. NIGHTTIME LIGHTING:

WHEN NIGHTTIME WORK IS REQUIRED, FLOODLIGHTS SHOULD BE USED TO ILLUMINATE FLAGGER STATIONS, EQUIPMENT CROSSINGS, AND OTHER AREAS WHERE EXISTING LIGHTING IS NOT ADEQUATE FOR THE WORK TO BE PERFORMED SAFELY.

IN NO CASE SHALL FLOODLIGHTS BE PERMITTED TO CREATE A DISABLING GLARE FOR THE DRIVER. THE ADEQUACY OF THE FLOODLIGHT PLACEMENT AND ELIMINATION OF POTENTIAL GLARE SHOULD BE CHECKED BY DRIVING THROUGH THE PROJECT.

12. NCHRP REPORT 350 CRASHWORTHY REQUIREMENTS:

TRAFFIC CONTROL DEVICES SHALL MEET THE EVALUATION CRITERIA IN NCHRP REPORT 350 OR IN MASH REPORT 2009 AS SUPPLEMENTED BY FHWA MEMORANDUM "IDENTIFYING ACCEPTABLE HIGHWAY SAFETY FEATURES," DATED JULY 25, 1997. AVAILABLE ON THE INTERNET AT http://safety.fhwa.dot.gov/roadway_dept/policy_guide/road_hardware/policy_memo/

ANY DEVICE NOT ADDRESSED BY THE TE STANDARDS MAY BE APPROVED ON A CASE BY CASE BASIS BY THE ENGINEER. THE DEVICE SHALL BE ACCOMPANIED BY AND INSTALLED ACCORDING TO MASH REPORT 2009. ANY DEVICE ACCEPTED PRIOR TO THE ADOPTION OF MASH REPORT 2009 USING CRITERIA FROM NCHRP REPORT 350 MAY REMAIN IN PLACE AND CONTINUE TO BE USED. ANY TRAFFIC CONTROL DEVICE ACCEPTED USING NCHRP REPORT 350 CRITERIA IS NOT REQUIRED TO BE TESTED UNDER MASH REPORT 2009. HOWEVER, NEW TRAFFIC CONTROL DEVICES NOT PREVIOUSLY EVALUATED MUST UTILIZE MASH REPORT 2009 FOR TESTING AND EVALUATION.

THE CONTRACTOR SHALL:

1) PROVIDE TO THE ENGINEER A COPY OF THE MANUFACTURER'S SELF-CERTIFICATION THAT ANY CATEGORY 1 (i.e. - PLASTIC CONICAL DELINEATORS, TUBULAR MARKERS, DRUMS WITHOUT ATTACHMENTS) AND CATEGORY 2 (i.e. - PORTABLE SIGN STANDS (WITH SIGNS), TYPE II AND III BARRICADES, AND VERTICAL PANELS) DEVICES USED ON THE PROJECT ARE NCHRP REPORT 350 OR MASH REPORT 2009 COMPLIANT.

2) PROVIDE TO THE ENGINEER A COPY OF THE ENTIRE FHWA ACCEPTANCE LETTER (WZ-xxx) FOR ANY CATEGORY 2 DEVICE (i.e. - PORTABLE SIGN STANDS (WITH SIGNS), TYPE II AND III BARRICADES, AND VERTICAL PANELS) USED ON THE PROJECT. WORK ZONE FHWA ACCEPTANCE LETTERS (WZ-xxx) ARE AVAILABLE ON THE INTERNET AT: http://safety.fhwa.dot.gov/roadway_dept/policy_guide/road_hardware/wzd/

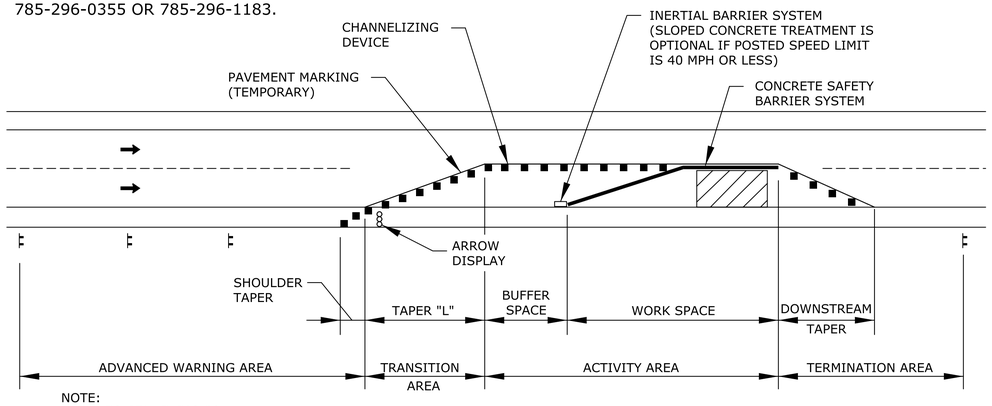
3) CERTIFY THAT THE TRUCK MOUNTED ATTENUATORS (TMA'S) (WHICH ARE DEFINED AS CATEGORY 3 DEVICES BY THE FHWA MEMORANDUM) MEET CURRENT CRASHWORTHY SPECIFICATIONS AS DEFINED ABOVE AND INCLUDE A COPY OF THE ENTIRE FHWA ACCEPTANCE LETTER. ALL CATEGORY 1 & 2 DEVICES SHALL BE NCHRP REPORT 350 OR MASH REPORT 2009 COMPLIANT.

13. LEAD IN CHANNELIZING DEVICES ON CENTERLINE:

TEMPORARY RUMBLE STRIPS MAY BE USED IN LIEU OF LEAD IN CENTERLINE CHANNELIZING DEVICES WHEN THE ROADWAY IS LESS THAN OR EQUAL TO 30' (FEET) INCLUDING PAVED SHOULDERS. WHEN EXTENUATING CIRCUMSTANCES EXIST, THE AREA ENGINEER MAY ELECT TO ELIMINATE BOTH THE LEAD IN CHANNELIZERS AND THE RUMBLE STRIPS.

14. TEMPORARY RUMBLE STRIPS:

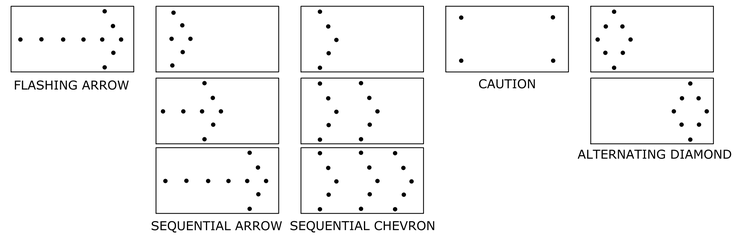
ALTERNATIVE TEMPORARY RUMBLE STRIP OPTIONS MAY BE AVAILABLE. PLEASE CONTACT THE TEMPORARY TRAFFIC CONTROL UNIT FOR MORE INFORMATION AT 785-296-0355 OR 785-296-1183.



NOTE:
REFER TO STD. TE702 FOR TAPER "L" FORMULA.

TYPICAL WORK ZONE COMPONENTS

ARROW DISPLAYS



ARROW DISPLAY ELEMENTS SHALL BE CAPABLE OF A MINIMUM 50 PERCENT DIMMING FROM THEIR FULL-RATED LAMP VOLTAGE. FULL LAMP VOLTAGE SHOULD BE USED DURING THE DAY AND DIMMED MODE SHALL BE USED AT NIGHT. FOR SHOULDER WORK, ROADSIDE WORK NEAR THE SHOULDER, BLOCKING THE SHOULDER, OR FOR TEMPORARY CLOSING ONE LANE ON A TWO-LANE, TWO-WAY ROADWAY, AN ARROW PANEL SHALL BE USED ONLY IN THE CAUTION MODE.

BUFFER SPACE

SPEED (MPH) ✳	*20*	*25*	*30*	*35*	*40*	*45*	*50*	*55*	*60*	*65*	*70*	*75*
LENGTH (ft)	*115*	*155*	*200*	*250*	*305*	*360*	*425*	*495*	*570*	*645*	*730*	*820*

✳ POSTED SPEED PRIOR TO WORK STARTING

NEITHER WORK ACTIVITY NOR STORAGE OF EQUIPMENT, VEHICLES, OR MATERIAL SHOULD OCCUR IN THE BUFFER SPACE. WHEN A PROTECTION VEHICLE IS PLACED IN ADVANCE OF THE WORK SPACE, ONLY THE SPACE UPSTREAM OF THE VEHICLE CONSTITUTES THE BUFFER SPACE.

IF TEMPORARY CONCRETE SAFETY BARRIER SYSTEM IS USED TO SEPARATE APPROACHING TRAFFIC FROM THE WORK SPACE, THE BARRIER SYSTEM SHALL BE CONSIDERED PART OF THE ACTIVITY AREA. A FULL LANE WIDTH SHOULD BE AVAILABLE THROUGHOUT THE LENGTH OF THE BUFFER SPACE. SEE TYPICAL WORK ZONE COMPONENTS.

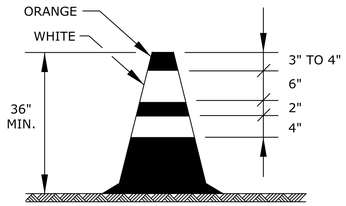
DRUM

CONICAL DELINEATOR

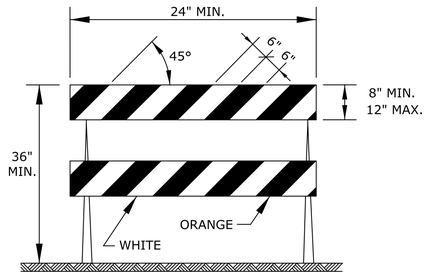
DRUMS AND CONICAL DELINEATORS SHALL HAVE AT LEAST TWO ORANGE AND TWO WHITE 6" TO 8" WIDE RETROREFLECTIVE STRIPES. ADDITIONAL STRIPES MAY BE NON-RETROREFLECTIVE. IF THERE ARE NON-RETROREFLECTIVE SPACES BETWEEN ADJACENT STRIPES, THEY SHALL BE NO MORE THAN 3" WIDE.

ALL RETROREFLECTIVE STRIPES ON DRUMS SHALL BE ASTM TYPE III SHEETING. THE WHITE STRIPES ON CONICAL DELINEATORS SHALL BE ASTM TYPE III SHEETING. ORANGE STRIPES ON ALL CONICAL DELINEATORS SHALL BE FLUORESCENT ORANGE ASTM TYPE IV SHEETING.



TRAFFIC CONE

TRAFFIC CONES MAY BE USED AS CHANNELIZING DEVICES FOR DAYTIME OPERATIONS ONLY. THEY WILL NOT BE PAID FOR SEPARATELY, BUT WILL BE SUBSIDIARY TO OTHER TRAFFIC CONTROL BID ITEMS. THE ENGINEER MAY REQUIRE THAT TRAFFIC CONES BE SUPPLEMENTED BY OTHER TRAFFIC CONTROL DEVICES IN CERTAIN SITUATIONS.

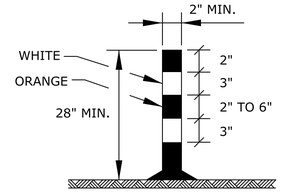


TYPE II BARRICADE

FOR RAILS LESS THAN 36" LONG, 4" WIDE STRIPES MAY BE USED.

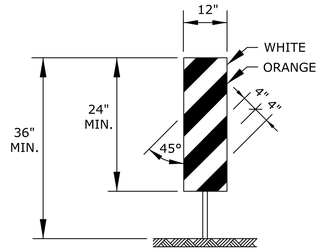
THE ENTIRE AREA OF BARRICADE RAILS, BOTH FRONT AND BACK, SHALL BE ASTM TYPE III SHEETING.

THE STRIPES SHALL SLOPE DOWNWARD TO THE TRAFFIC SIDE FOR CHANNELIZATION.



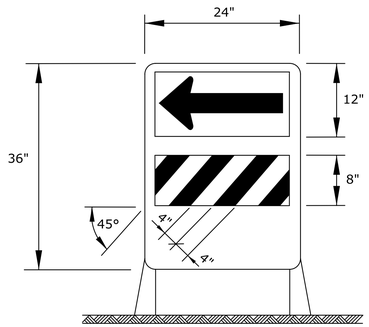
TUBULAR MARKER

THE TWO WHITE RETROREFLECTIVE STRIPES SHALL BE ASTM TYPE III SHEETING. STRIPING AS SHOWN FOR UP TO 42".



VERTICAL PANEL

THE ENTIRE AREA OF VERTICAL PANELS, BOTH FRONT AND BACK, SHALL HAVE ASTM TYPE III SHEETING. THE STRIPES SHALL SLOPE DOWNWARD TO THE TRAFFIC SIDE FOR CHANNELIZATION.



DIRECTION INDICATOR BARRICADE

THE ARROW PANEL SHALL BE BLACK ON FLUORESCENT ORANGE ASTM TYPE IV SHEETING. THE STRIPES SHALL BE ORANGE AND WHITE ASTM TYPE III SHEETING SLOPING DOWNWARD IN THE DIRECTION TRAFFIC IS TO PASS.

THE DIRECTION INDICATOR BARRICADE SHALL BE USED IN SERIES TO DIRECT THE MOTORIST INTO THE INTENDED LANE OF TRAVEL.

THE ARROW PANEL SHOULD NOT BE VISIBLE TO OPPOSING TRAFFIC.

TAPER FORMULAS:

L = WS FOR SPEEDS OF 45 MPH OR MORE

$L = WS^2/60$ FOR SPEEDS OF 40 MPH OR LESS

WHERE: L = MINIMUM LENGTH OF TAPER IN FEET
S = NUMERICAL VALUE OF POSTED SPEED PRIOR TO WORK STARTING IN MPH
W = WIDTH OF OFFSET IN FEET

CHANNELIZER PLACEMENT:

(A) THE SPACING BETWEEN DEVICES IN TRANSITION AREA (TAPER) SHOULD NOT EXCEED A DISTANCE IN FEET EQUAL TO 1/2 THE POSTED SPEED LIMIT IN MPH PRIOR TO WORK STARTING.

(B) THE SPACING BETWEEN DEVICES IN THE ADVANCED WARNING AREA AND THE ACTIVITY AREA SHOULD NOT EXCEED A DISTANCE IN FEET EQUAL TO TWO TIMES THE POSTED SPEED LIMIT IN MPH PRIOR TO WORK STARTING.

(C) CHANNELIZING DEVICES SHALL BE PLACED FOR OPTIMUM VISIBILITY, NORMALLY AT RIGHT ANGLES TO THE TRAFFIC FLOW.

(D) CHANNELIZING DEVICES PLACED ALONG SHOULDER EDGES OR IN DROPOFFS SHALL HAVE A MINIMUM OF 24" FROM THE TOP OF THE CHANNELIZING DEVICE TO THE TOP OF THE PAVEMENT.

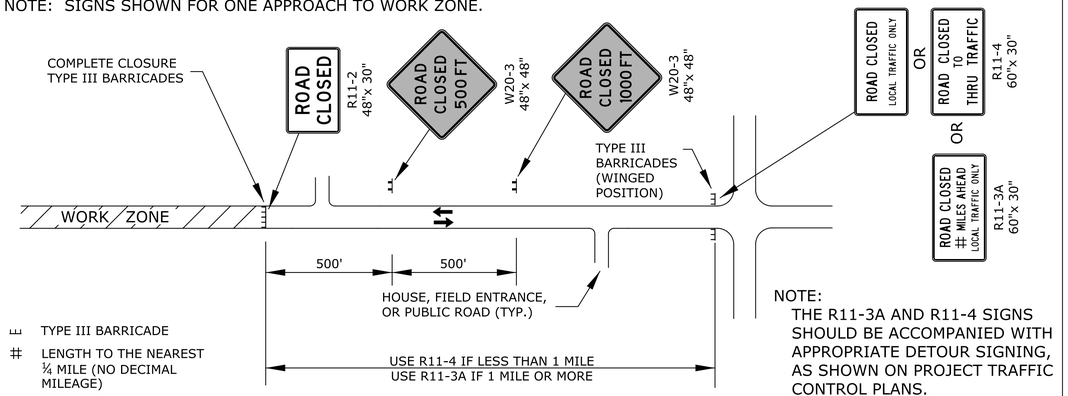
NOTE: SIGNS SHOWN FOR ONE APPROACH TO WORK ZONE.



NOTE:
THE R11-3A AND R11-4 SIGNS SHOULD BE ACCOMPANIED WITH APPROPRIATE DETOUR SIGNING, AS SHOWN ON PROJECT TRAFFIC CONTROL PLANS.

FIGURE 1: TYPICAL SIGNING FOR ROAD CLOSURE

NOTE: SIGNS SHOWN FOR ONE APPROACH TO INTERSECTION (WORK ZONE).

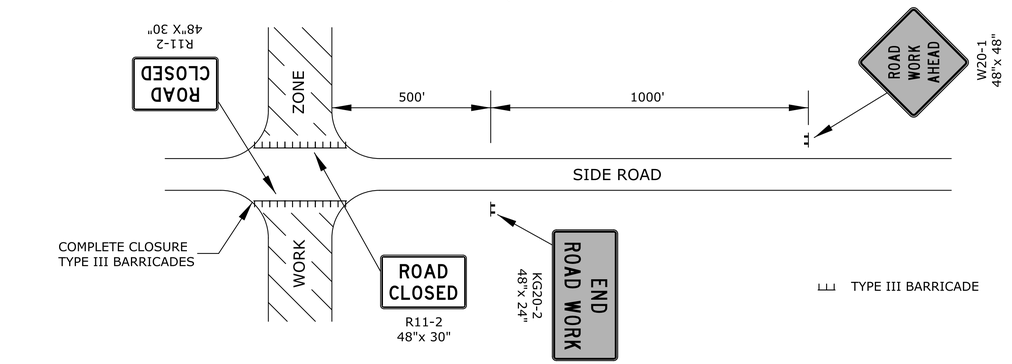


FIGURE 2: TYPICAL SIGNING FOR SIDE ROAD OPEN

NOTE: SIGNS SHOWN FOR ONE APPROACH TO INTERSECTION (WORK ZONE).

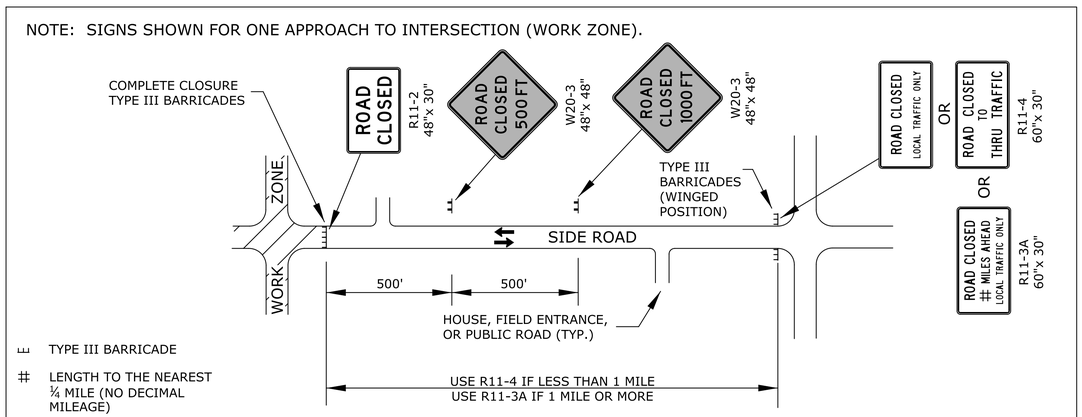

FIGURE 3: TYPICAL SIGNING FOR SIDE ROAD CLOSED

NOTE: SIGNS SHOWN FOR ONE APPROACH TO WORK ZONE.

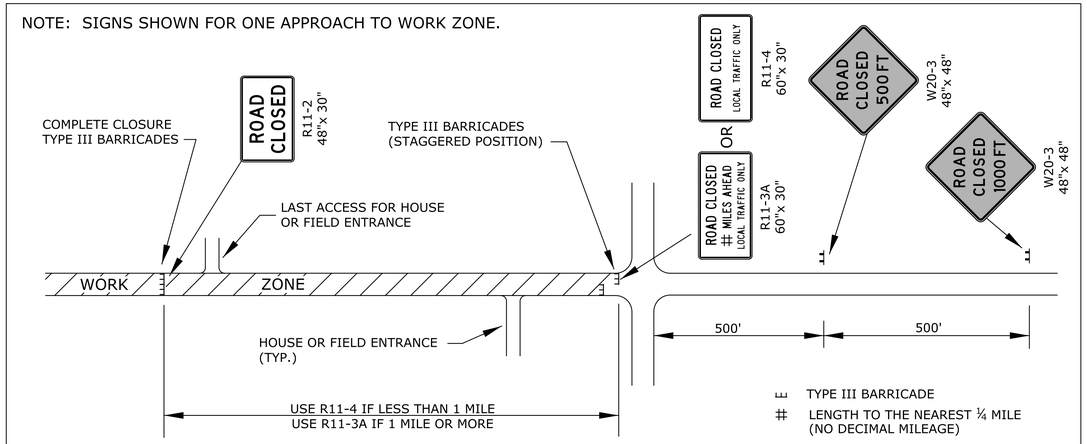

FIGURE 4: TYPICAL SIGNING FOR ROAD CLOSURE - LOCAL TRAFFIC ACCESS

NOTES:

1. SIGNS:

THE R11-4 (ROAD CLOSED TO THRU TRAFFIC OR ROAD CLOSED LOCAL TRAFFIC ONLY) SIGN SHALL BE USED WHEN THE DISTANCE TO THE POINT OF COMPLETE CLOSURE OF THE ROADWAY IS LESS THAN 1 MILE.

THE R11-3A (ROAD CLOSED # MILES AHEAD LOCAL TRAFFIC ONLY) SIGN SHALL BE USED WHEN THE DISTANCE TO THE POINT OF COMPLETE CLOSURE OF THE ROADWAY IS 1 MILE OR GREATER.

THE WORDS "BRIDGE OUT" (OR BRIDGE CLOSED) MAY BE SUBSTITUTED FOR THE WORDS "ROAD CLOSED" ON THE R11-3A OR R11-4 SIGN WHERE APPLICABLE.

2. BARRICADE PLACEMENT:

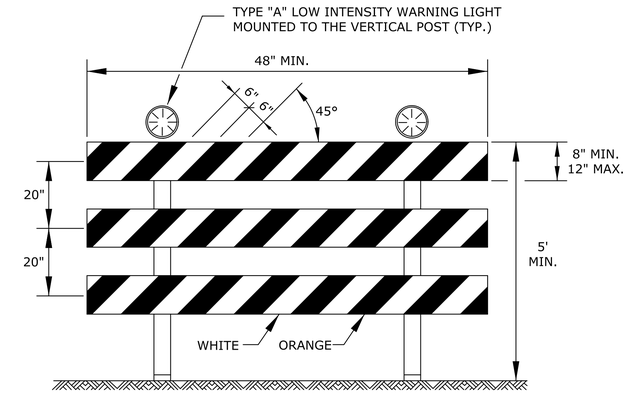
A) COMPLETE ROAD CLOSURE

WHEN A ROADWAY IS CLOSED, TYPE III BARRICADES SHALL BE PLACED END-TO-END TO COMPLETELY COVER THE ROADWAY AND SHOULDERS. WHEN ACCESS MUST BE ALLOWED FOR CONSTRUCTION OR OTHER OFFICIAL/GOVERNMENT VEHICLES, TYPE III BARRICADES SHALL BE LONGITUDINALLY STAGGERED FAR ENOUGH APART FROM ONE ANOTHER TO ALLOW SAFE PASSAGE OF VEHICLES AND MAINTAIN THE APPEARANCE OF A CLOSED ROADWAY. TYPE III BARRICADES SHALL BE REALIGNED AND PLACED END-TO-END TO DENY ANY ACCESS WHEN THE CONSTRUCTION ACTIVITY HAS CEASED FOR THE DAY.

B) ROAD CLOSED - LOCAL TRAFFIC

AS SHOWN IN FIGURE 4, WHEN LOCAL TRAFFIC MUST BE ALLOWED ACCESS INTO THE WORK ZONE, TYPE III BARRICADES SHALL BE LONGITUDINALLY STAGGERED TO MAINTAIN THE APPEARANCE OF A CLOSED ROADWAY. A SECOND LINE OF END-TO-END TYPE III BARRICADES SHALL BE PLACED JUST BEYOND THE LAST ACCESS POINT IN THE WORK ZONE, TO COMPLETELY CLOSE THE ROADWAY AS DESCRIBED IN NOTE 2-A.

AS SHOWN IN FIGURE 1 AND FIGURE 3, AT THE POINT WHERE THRU TRAFFIC MUST DETOUR AND LOCAL TRAFFIC CAN PROCEED TO THE LOCATION WHERE THE ROADWAY IS COMPLETELY CLOSED, THE R11-3A (ROAD CLOSED # MILES AHEAD LOCAL TRAFFIC ONLY) OR R11-4 (ROAD CLOSED LOCAL TRAFFIC ONLY OR ROAD CLOSED TO THRU TRAFFIC) SIGN SHALL BE USED WITH TYPE III BARRICADES (WINGED POSITION), PLACED ON THE SHOULDERS OF ROADWAY.



TYPE III BARRICADE WITH LIGHTS

THE ENTIRE AREA OF BARRICADE RAILS, BOTH FRONT AND BACK, SHALL HAVE ASTM TYPE III SHEETING.

THE STRIPES SHALL SLOPE DOWNWARD TO THE SIDE TRAFFIC IS TO PROCEED OR TOWARD THE CENTER OF THE ROADWAY AT ROAD CLOSURES.

APPROVED SIGNS MOUNTED ON TYPE III BARRICADES SHOULD NOT COVER MORE THAN 50% OF THE TOP TWO RAILS OR 33% OF THE TOTAL AREA OF THE THREE RAILS.

WHEN BARRICADES ARE PLACED END-TO-END OR STAGGERED, A TYPE "A" LOW INTENSITY WARNING LIGHT SHALL BE MOUNTED TO THE VERTICAL POST NEAR EACH OUTSIDE CORNER OF THE END BARRICADES.

NO.	DATE	REVISIONS	BY	APP'D

1. MAINTENANCE:

THE CONTRACTOR SHALL MAINTAIN ALL SIGNS AND DEVICES IN AN UPRIGHT POSITION. THE CONTRACTOR SHALL CLEAN OR REPLACE ANY DAMAGED OR ILLEGIBLE SIGN OR DEVICE AS DIRECTED BY THE ENGINEER.

2. EXISTING SIGNS:

IF EXISTING SIGNS THAT ARE TO REMAIN (WHETHER DENOTED ON THE PLANS OR NOT) INTERFERE WITH CONSTRUCTION WORK, THE CONTRACTOR SHALL REMOVE, STORE, AND RESET THE SIGNS. THIS SHALL BE SUBSIDIARY TO OTHER TRAFFIC CONTROL BID ITEMS. SIGNING DAMAGED BY THE CONTRACTOR SHALL BE REPLACED AT THE CONTRACTOR'S EXPENSE.

3. CONFLICTING SIGNS, SIGNS NOT IN USE, AND TRAFFIC SIGNALS:

SIGNS AND TRAFFIC SIGNALS THAT ARE IN CONFLICT WITH THE TRAFFIC CONTROL PLAN OR DO NOT APPLY TO THE TRAFFIC OPERATIONS SHALL BE IMMEDIATELY REMOVED, TURNED SO NOT VISIBLE TO TRAFFIC FROM ANY DIRECTION, OR COMPLETELY COVERED WITH ADEQUATE OPAQUE BREATHABLE MATERIAL. TAPE SHALL NOT BE APPLIED TO THE FACE OF THE SIGN.

4. PORTABLE AND POST MOUNTED SIGNS:

TEMPORARY TRAFFIC CONTROL SIGNS THAT ARE ANTICIPATED TO REMAIN IN PLACE FOR 3 DAYS OR LESS ARE CONSIDERED "PORTABLE." PORTABLE SIGNS SHALL BE MOUNTED ON AN APPROVED SUPPORT AT A MINIMUM HEIGHT OF 12" ABOVE THE TRAVELED WAY. TRAFFIC CONTROL SIGNS IN PLACE FOR OVER 3 DAYS ARE REQUIRED TO BE MOUNTED ON APPROVED POSTS. A MINIMUM OF 42" OF THE APPROVED POST MUST BE BELOW THE GROUND SURFACE WITH ADEQUATE BACKFILL AND COMPACTION. ALL POSTS AT MINIMUM SHALL EXTEND TO THE TOP EDGE OF THE SIGN AND NO GREATER THAN 6" ABOVE THE SIGN.

WHEN THE SIGN WIDTH IS EQUAL TO OR GREATER THAN 9', THREE OR MORE WOOD POSTS MAY BE USED WITH A MINIMUM OF 4' BETWEEN THE CENTERLINE OF EACH POST. ALL SIGNS LESS THAN 9' IN WIDTH SHALL USE A MAXIMUM OF TWO WOOD POSTS.

"ROLL-UP" SIGNS MAY BE USED FOR PORTABLE WARNING SIGNS. THEY MUST BE FLUORESCENT ORANGE ASTM TYPE IV SIGNS OF OPAQUE MATERIAL. MESH SIGNS ARE NOT ALLOWED.

IN THE CASE OF HITTING ROCK WHEN DRIVING POSTS
1. SHIFT THE SIGN LOCATION. DO NOT VIOLATE MINIMUM SIGN SPACING.
2. WITH THE ENGINEER'S APPROVAL, USE ACCEPTABLE ALTERNATIVE SIGN STANDS.

5. SHEETING:

ALL ORANGE SIGNS SHALL HAVE FLUORESCENT ORANGE ASTM TYPE IV SHEETING. ALL OTHER SIGNS SHALL HAVE ASTM TYPE III SHEETING OF STANDARD COLORS.

6. SIGNS INVOLVING SPEEDS:

THE W3-5 (SPEED REDUCTION) SHOULD BE USED ONLY IF THE ENGINEER DETERMINES THAT A REDUCED SPEED IS REQUIRED ON THE PROJECT.

THE KM4-20 (WORK ZONE) PLAQUE SHALL BE PLACED ABOVE ALL SPEED LIMIT SIGNS, (R2-1), EXISTING AND TEMPORARY. MOUNT THE WORK ZONE PLAQUES TO THE POST. DO NOT OVERLAP THE R2-1 AND KM4-20 SIGNS.

FOR SPEEDS OF 30 MPH OR LESS, THE W1-1(TURN) OR W1-3(REVERSE TURN) SHOULD BE USED. FOR SPEEDS OF 35 MPH OR MORE, THE W1-2(CURVE) OR W1-4(REVERSE CURVE) SHOULD BE USED. THE W13-1(MPH) IS TO BE ELIMINATED IF THE ADVISORY SPEED IS WITHIN 5 MPH OF THE SPEED LIMIT.

7. SIGNS CONTROLLING WORK ZONE:

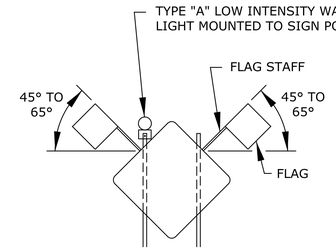
THE KG20-2(END ROAD WORK) SHOULD BE PLACED 500' FROM THE END OF THE ACTUAL WORK SPACE, NOT NECESSARILY AT THE EXTREME LIMITS OF THE PROJECT. THE KG20-2 SHOULD BE MOUNTED ON TWO POSTS. THE KG20-2 MAY BE MOUNTED ON ONE POST IF IN URBAN AREAS WHERE UTILITIES ARE A PROBLEM AND WIND LOADS ARE NOT AN ISSUE.

WHERE TWO WORK ZONES ARE LESS THAN 1 MILE APART IN RURAL AREAS OR ¼ MILE APART IN URBAN AREAS, THE KG20-2(END ROAD WORK) FOR THE FIRST WORK ZONE AND THE W20-1(ROAD WORK) FOR THE SECOND WORK ZONE SHOULD BE ELIMINATED.

8. WARNING LIGHTS ON SIGNS:

A TYPE "A" LOW INTENSITY WARNING LIGHT IS AN L.E.D. BI-DIRECTIONAL FLASHING WORK ZONE WARNING LIGHT. TYPE "A" LOW INTENSITY WARNING LIGHTS SHOULD BE USED WITH ALL CONSTRUCTION ACTION WARNING SIGNS AND SHALL NOT BE USED ON SIGNS MOUNTED LESS THAN 5' HIGH ON TEMPORARY SUPPORTS. ON ALL OTHER CONSTRUCTION WARNING SIGNS, TYPE "A" LOW INTENSITY WARNING LIGHTS ARE TO BE USED AS DIRECTED BY THE ENGINEER.

TYPE "A" LOW INTENSITY WARNING LIGHTS SHALL BE MAINTAINED SO AS TO BE CAPABLE OF BEING VISIBLE ON A CLEAR NIGHT FROM A DISTANCE OF 3000 FT. IF A TYPE "A" LOW INTENSITY WARNING LIGHT HAS A SEPARATE BATTERY CASE, THE BATTERY CASE SHALL BE MOUNTED NO HIGHER THAN 12" ABOVE THE GROUND AND MOUNTED BEHIND THE SIGN POST. A TYPE "A" LOW INTENSITY WARNING LIGHT WHERE THE LENS AND BATTERY ARE ONE UNIT SHALL BE MOUNTED ON THE TEMPORARY SIGN POST NEAREST TO THE TRAVELED WAY. FLAGS SHALL NOT INTERFERE WITH THE VISABILITY OF THE TYPE "A" LOW INTENSITY WARNING LIGHT.



TWO (2) 18" x 18" FLUORESCENT RED-ORANGE FLAGS SHALL BE ATTACHED (IN THE POSITION SHOWN) ON THE W20-2(DETOUR),W1-1(TURN), W1-2(CURVE), W1-3(REVERSE TURN), W1-4(REVERSE CURVE), W3-3(SIGNAL AHEAD), W4-2(LANE REDUCTION), W20-4(ONE LANE ROAD), W20-5(LANE CLOSED), W20-7A(FLAGGER), AND W3-4 (BE PREPARED TO STOP) SIGNS AND ANY OTHER ACTION SIGNS AS SHOWN ON THE PLANS OR DIRECTED BY THE ENGINEER. THE FLAGS AND STAFFS ARE TO BE ATTACHED IN SUCH A MANNER THAT THE SIGN WILL NOT BE OBSCURED. THE FLAGS MAY BE EITHER A CLOTH OR VINYL MATERIAL. THE FLAGS SHALL BE SUBSIDIARY TO THE CONSTRUCTION SIGN BID ITEMS.

MINIMUM ADVANCE WARNING SIGN SPACING (IN FEET):

	A	*B*	*C*
URBAN (40 MPH OR LOWER)	*100*	*100*	*100*
URBAN (45 MPH OR HIGHER)	*350*	*350*	*350*
RURAL (55 MPH OR LOWER)	*500*	*500*	*500*
RURAL (60 MPH OR HIGHER)	*750*	*750*	*750*
EXPRESSWAY/FREEWAY	*1000*	*1500*	*2640*

THE MINIMUM SPACING BETWEEN SIGNS SHALL BE NO LESS THAN 100', UNLESS DIRECTED BY THE ENGINEER.

THE SPACING BETWEEN ANY SIGNS MAY BE INCREASED BEYOND THE MINIMUM VALUES IN THE TABLE ABOVE AS APPROVED BY THE ENGINEER IN ORDER TO MAXIMIZE VISIBILITY.

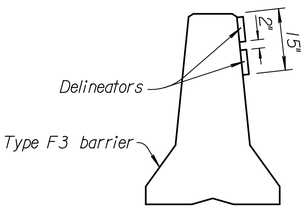
PLAN (SECTION)



DELINEATOR DETAILS

GENERAL NOTES:

MATERIAL: Use ASTM A615, Grade 60 reinforcing bars, except for the loop bars (d_1, d_2 and d_3).

The loop bars (d_1, d_2 and d_3) shall be ¾" smooth steel bars with a minimum yield of 60 ksi, a tensile strength of not less than 1.25 times the yield strength but a minimum of 80 ksi, a minimum 14% elongation in 8 inches, and passing a 180 degree bend test using a 3.5 D pin bend diameter. The loops shall be installed within ⅛" of the plan dimensions.

Use air-entrained concrete with f'c = 5,000 p.s.i.

SECTION: The section furnished must generally comply with dimensions shown. Requests for minor variations in section geometry and attachments may be submitted to the Engineer for approval.

LIFTING SLOTS: Lifting slots shall be constructed where specified on the plans to facilitate the drainage of water after installation on the roadway.

TEMPORARY CONCRETE SAFETY BARRIER: Furnishing and placing of all materials when required and all labor and equipment required to position the temporary barrier shall be included in the Contract unit price bid for "Concrete Safety Barrier (Type F3)(Temporary)". Any relocation of the barrier required for the project shall be paid in accordance with the Special Provisions under the bid item "Concrete Safety Barrier (Type F3) (Temporary-Relocate)". Unless otherwise noted on the Plans, the Temporary Concrete Safety Barrier shall become the property of the Contractor and shall be removed from the site upon acceptance of the completed project. Approximate weight of one unit equals 2.7 tons.

SURFACE PREPARATION: Barrier shall be placed on a paved surface. All loose dirt and sand shall be removed from the roadway surface just prior to placement of the barrier.

MARKING: The left end (ǂ) of each barrier shall be permanently marked by stamping or forming into the barrier the following information:

- *Type F3*
- *Manufacturer code (as specified by KDOT Bureau of Const. & Maint.)*
- *Date manufactured (month and year)*

DELINEATION: Delineators shall be spaced on 50' centers, except through curves having 1900' or greater curvature where they shall be spaced on 25' centers.

The delineation shall be mounted on the side of the Temporary Concrete Safety Barrier with two delineators at each location. Each delineator shall have a minimum height-to-width ratio of 1.75, and a minimum reflective surface area of 7 sq. in.. The delineators shall be affixed to the Temporary Concrete Safety Barrier as recommended by the manufacturer.

Delineators shall be attached to bridge rail or other structures in construction zones when roadway is narrowed and traffic is adjacent to the structure. The method and location of placement shall be similar to permanent barrier delineation.

When traffic flow is in one direction, the delineators shall be yellow when used on the left, white when used on the right. When traffic flow is in both directions delineators shall be placed back-to-back, and shall correspond to the color of the edge line.

The work and materials required for the installation of delineators as mentioned shall be subsidiary to the bid item "Concrete Safety Barrier (Type F3) (Temporary).

Note: If necessary, include Standard Drawing RD622A for Taper Section, Standard drawing RD622B for anchor and tie down details, Standard Drawing RD622C for Bridges with thermal expansion of 1½" or greater and Standard Drawing RD622D for Barrier Layouts.

Note: The Contractor shall be responsible for maintaining a clear area, shown as dimension "A" on Standard Drawing RD622B. The clear area is located behind the Temporary Concrete Safety Barrier and shall be kept free of any equipment, material stockpiles or other obstacles.

INERTIAL BARRIER SYSTEM			
Station	Side	Design Speed	Comments
54+33.77	Lt.	35 MPH	Sequence 1
54+36.65	Lt.	35 MPH	Sequence 2

GENERAL NOTE

This drawing details general configurations for Inertial Barrier Systems. Some project specific conditions may require variations which are designed to meet prevailing criteria.

Use Inertial Barrier System consisting of the units as shown for the specified design speed, all hardware and attachments.

Install Inertial Barrier System on a flat, stable base with cross-slope no steeper than 10:1. See Manufacturer's recommendations for module materials and method of installation.

See standard specifications for mixture to fill modules requirements.

Provide a 6" spacing between modules and one foot between the end of concrete barrier or other rigid object.

When installed as part of project traffic control, the bid item "Inertial Barrier" includes the original installation and required relocations.

Keep available replacement modules to replace any size module used on site, Engineer's direction.

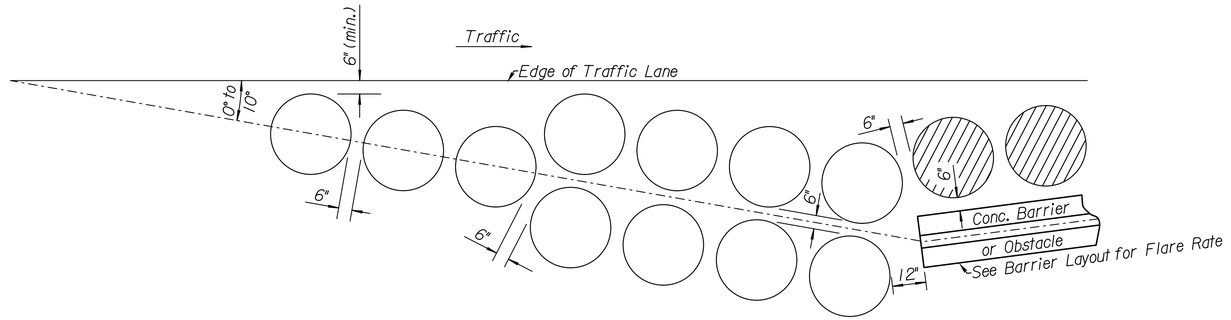
Inertial Barrier System modules damaged by the Contractor during relocation of Inertial Barrier System are replaced at the Contractor's expense.

Module weights shown are in pounds.

Install 270 square inches of Type II High Performance (vertical, rectangular or diamond shape) reflective sheeting on first module of Inertial Barrier System facing traffic.

Where sufficient space is available the Inertial Barrier System may be aligned at an angle, not to exceed 10°, in the direction of approach traffic.

No portion of the system shall encroach into the approach traffic lane.



TYPICAL PLAN of INERTIAL BARRIER

When two-way traffic is adjacent to only one side of Concrete Barrier or Obstacle, these additional modules will be placed on the Traffic Side of Concrete Barrier or Obstacle. Traffic adjacent to both sides of the Concrete Barrier or Obstacle require an additional set of modules each side if approach traffic is exposed to the back portion of the Inertial Barrier. These additional modules are not required along the sides of Concrete Barrier or Obstacle when it's location is outside the Clear Zone or one-way directional traffic.

6	RETAINING WALL SECTIONS "A" AND "C"
7	RETAINING WALL SECTION "B"
8	GRADING AND LAYOUT @ MERRIAM MARKET
9	GENERAL NOTES AND STANDARD DETAILS
10	PEDESTRAIN BRIDGE PLAN AND ELEVATION
11	PEDESTRIAN BRIDGE DETAILS

GENERAL NOTES

1. Information and references to existing conditions shown on these plans are the best information and references available to Shafer, Kline & Warren, Inc., Consulting Engineers, at the time of plan preparation. The plans reflect information provided by field surveys, plats and plans furnished by others who limit their guarantees and responsibilities.

2. By use of these plans the Contractor agrees that he shall be solely responsible for the safety of the construction workers and of the public.

3. The Technical Specifications and Design Criteria for Public Improvements and all amendments thereto for Johnson County Park and Recreation, shall be the specifications for these plans as though fully set forth herein.

4. All existing utilities indicated on the drawings are according to the best information available to the Engineer; however, all utilities actually existing may not be shown. Utilities damaged through the negligence of the contractor to obtain the location of same shall be repaired or replaced.

5. Johnson County Park and Recreation plan review is only for general conformance. Johnson County Park and Recreation is not responsible for the accuracy and adequacy of the design, or dimensions and elevations which shall be confirmed and correlated at the job site. Johnson County Park and Recreation through approval of these documents assumes no responsibility other than as stated above for the completeness and/or accuracy of this document.

6. The Contractor shall thoroughly review and become familiar with the specifications and special conditions of the contract documents, prior to beginning construction on this project.

7. The Contractor shall have one (1) signed copy of the plans (approved by Johnson County Park and Recreation) and one (1) copy of the Specifications at the job site at all times.

8. Construction of the improvements shown on or implied by this set of drawings shall not be initiated or any part thereof undertaken until Johnson County Park and Recreation is notified of such intent, and all required and properly executed bonds and inspection fees are received and approved.

9. The Contractor shall not be allowed to work Sundays or Holidays. The work hours for Monday through Saturday shall be from 8:00 AM TO 6:00 PM.

10. The Contractor will furnish flagmen and other personnel necessary to provide required traffic control which shall include adequate signs, barricades, warning lights, and all other equipment in accordance with the current manual on uniform traffic control devices and procedures.

11. All waterline mains, sanitary sewer mains and stormwater drainage crossings and other utilities under proposed pavements shall be in place or a casing pipe provided for future installation prior to the placement of the curb and gutter.

12. Siltation and erosion control measures shall be in place prior to the disturbance of the ground.

13. The Contractor is responsible for providing berms, silt fences, straw bales, or other means to prevent erosion from reaching Turkey Creek. In the event the prevention measures are not effective, the contractor shall remove any debris and erosion and restore the stream bed to original or better condition.

14. By use of these plans, the Contractor shall be solely responsible for all areas that they or their subcontractors disturb, both within and beyond the project limits. These areas shall be restored, re-seeded, or re-sodded to a state that is equal to or better than the prior condition. The Contractor shall bear the related expenses, unless denoted otherwise within the contract documents.

15. All trees, shrubs, bushes, and brush, within the grading limits shall be removed by the Contractor. Large trees, within the construction easements that are not shown on the plans, shall be brought to the attention of the Engineer prior to disturbance. Exceptionally good trees shall be spared by adjusting grading during construction, as directed by the Engineer. All trees, within the construction limits, to be saved shall have their trunks physically protected, prior to construction operations, by methods approved by the Engineer.

16. All concrete for the project shall comply with the standards and specifications of the Johnson County Concrete Board. Structural concrete shall be 5000 PSI. Non structural concrete shall be 4000 PSI.

UTILITY NOTES

1. Visual indications of utilities are as shown. Underground locations shown, as furnished by the respective utility companies, are approximate and shall be verified in the field at the time of construction. For actual field locations of underground utilities, call 1-800-344-7233, Kansas or 1-800-344-7483, Missouri.

2. The Contractor shall be responsible for contacting all utility companies for field location of all underground utility lines prior to any excavation and for the coordination and scheduling with utility owners of all work required to resolve conflicts with installations, constructions, excavations, removals, placements, relocation and other miscellaneous work shown upon these plans or required witnin contract documents.

3. All manholes, catch basins, utility valves and meter pits shall be adjusted or rebuilt to grade as required.

4. The name and telephone number of utility companies, even if remotely involved with this project are as follows:

POWER:	KPL Electric 913-768-3293
GAS:	KPL Gas Service Co. 913-599-8985 Williams Pipe Line Co. 913-677-2166

GENERAL NOTES FOR PRE-CAST MANHOLES

1. Reinforcement in all sections shall equal or exceed A.S.T.M. C-478 specifications.
2. Mastic material to be used at all sections joints. O-Rings may be used for joints below the cone section, but the cone section itself shall not have O-ring joints. Ⓔ
3. Standard cast iron manhole steps to be Clay & Bailey Manufacturing Co. No. 2102 or approved equal. Steel core, plastic coated steps may be used (M.A. Ind., Inc. No. PS1-PF, PS2-PF, or approved equal).
4. All manhole rings shall be set in a minimum of two (2) rows of 3/4 to 1 inch pre-formed bitumastic joint sealer.
5. All manhole rings to be placed in pavement or in areas to be subsequently paved shall have "Machined Horizontal Bearing Surfaces" and shall comply with Class #25 as established in ASTM A-48.

ALL MANHOLE RINGS AND COVERS SHOWN IN PLANS TO BE "BOLT- DOWN" TO BE CLAY & BAILEY MANUFACTURING CO. NO. 20140R, NEENAH R-1915-F2 OR APPROVED EQUAL. AN EXTRA PAYMENT FOR FURNISHING "BOLT-DOWN" RING AND COVER AS SHOWN IN PLANS WILL NOT BE MADE, BUT SHALL BE CONSIDERED AS SUBSIDIARY TO THE ITEM, "STANDARD MANHOLE-6".

1. POSTS WHICH SUPPORT THE SILT FENCE SHALL BE INSTALLED ON A SLIGHT ANGLE TOWARD THE ANTICIPATED RUNOFF SOURCE AND SPACED AT A MAX. 8' APART OR TO SILT FENCE MANUFACTURER SPECIFICATIONS, WHICHEVER IS STRICTER.
2. SILT FENCE SHALL BE TRENCHED IN WITH A SPADE OR MECHANICAL TRENCHER SO THAT THE DOWNSLOPE FACE OF THE TRENCH IS FLAT AND PERPENDICULAR TO THE LINE OF FLOW..
3. THE TRENCH SHOULD BE APPROXIMATELY 8" DEEP 3-4" WIDE TO ALLOW FOR THE SILT FENCE TO BE LAID IN THE GROUND AND BACKFILLED.
4. SILT FENCE SHOULD BE SECURELY FASTENED TO EACH SUPPORT POST OR TO WOVEN WIRE WHICH IS IN TURN ATTACHED TO THE FENCE POSTS, AND SHOULD NOT EXCEED 18" ABOVE THE GROUND SURFACE.
5. WOVEN WIRE SUPPORT SHALL BE A MINIMUM 12 GAUGE WITH A MAXIMUM OF 6"x6" OPENING. WOVEN WIRE SUPPORT SHALL BE INSTALLED FOR FLOWS LONGER THAN 200 FEET.
6. INSPECTION SHALL BE FREQUENT AND REPAIR OR REPLACEMENT SHALL BE MADE PROMPTLY AS NEEDED.
7. SILT FENCE SHALL BE REMOVED WHEN IT HAS SERVED ITS USEFULNESS SO AS NOT TO BLOCK OR IMPEDE STORM FLOW OR DRAINAGE.
8. SEDIMENT TRAPPED BY THIS PRACTICE SHALL BE UNIFORMLY DISTRIBUTED ON THE SOURCE AREA PRIOR TO TOPSOILING.
9. SILT FENCE SHALL BE MIRAFI-100X FILTER FABRIC OR APPROVED EQUAL.

1. GENERAL

1.1. DESIGN CRITERIA:

A. DESIGN LOADING:

1. EARTH 120 LBS/ CU. FT. EQUIVALENT FLUID PRESSURE 45 LBS/ CU. FT.

B. DESIGN UNIT STRESSES:

1. CONCRETE: JOHNSON COUNTY CONCRETE BOARD MIX JCCB5K, f'c = 5000 PSI.

2. REINFORCING STEEL (GRADE 60) fy = 60000 PSI.

3. STEEL PILING A709 GRADE 36 = 9 KSI

4. STRUCTURAL STEEL TUBING HANDRAIL A500 GRADE B

1.2. STRUCTURAL DESIGN DRAWINGS SHOW THE INTENT OF REQUIRED CONSTRUCTION AND SPECIFIC CONSTRUCTION AS NEEDED TO FACILITATE CLEAR DETAILING. FOR SPECIFIC CONDITIONS NOT SHOWN, THE CONTRACTOR SHALL PROVIDE DETAILS OF CONSTRUCTION SIMILAR TO THOSE SHOWN. VERIFY ALL EXISTING CONDITIONS, DIMENSIONS, AND ELEVATIONS PRIOR TO COMMENCING WORK. NOTIFY THE STRUCTURAL ENGINEER IN WRITING OF DISCREPANCIES OR CONTRADICTIONS ENCOUNTERED PRIOR TO EXECUTING ANY AFFECTED CONSTRUCTION.

1.3. CONSTRUCTION PRACTICE AND THE DESIGN, ADEQUACY, AND SAFETY OF TEMPORARY BRACING, SHORING, SUPPORTS, ETC., SHALL REMAIN THE SOLE RESPONSIBILITY OF THE CONTRACTOR.

1.4. BEFORE EXECUTING ANY WORK, THE CONTRACTOR SHALL EXAMINE ACTUAL JOB CONDITIONS AND REPORT TO THE ENGINEER ANY ERROR, OMISSION, OR DISCREPANCY AFFECTING WORK. REFER TO THE ADDITIONAL DRAWINGS IN THIS SET FOR INSERTS, SLEEVES, OPENINGS, EMBEDS, PADS, CURBS, ATTACHMENTS, AND OTHER ITEMS NOT SHOWN HEREIN AFFECTING STRUCTURAL WORK BUT NOT INDICATED ON THE STRUCTURAL PLANS.

1.5. CONTRACTOR SHALL SUBMIT SHOP DRAWINGS FOR REVIEW FOR CONFORMANCE WITH THE DESIGN CONCEPT. THE SHOP DRAWINGS SHALL BE PREPARED UNDER THE DIRECT SUPERVISION OF A LICENSED PROFESSIONAL ENGINEER REGISTERED IN THE STATE WHERE THE PROJECT IS TO BE CONSTRUCTED. SHOP DRAWINGS MUST BE SUBMITTED TO AND BE CHECKED BY THE CONTRACTOR AND SUBCONTRACTOR AND BEAR THE CHECKERS INITIALS BEFORE SUBMISSION TO THE ENGINEER FOR APPROVAL. NO FABRICATION SHALL PROCEED BEFORE SHOP DRAWINGS COVERING THAT WORK HAVE BEEN APPROVED.

1.6. THESE NOTES TO BE READ IN CONJUNCTION WITH ANY WRITTEN SPECIFICATIONS AND THESE DRAWINGS. IN THE EVENT OF A CONFLICT THE ENGINEER SHALL BE NOTIFIED FOR CLARIFICATION.

1.7. THE OWNER OR HIS REPRESENTATIVE RESERVES THE RIGHT TO INSPECT ANY MATERIAL, FABRICATION, OR WORKMANSHIP AT ANY TIME IN FIELD OR SHOP FOR CONFORMANCE TO THE SPECIFICATIONS AND DRAWINGS.

1.8. DO NOT BACKFILL BEFORE 7 DAYS AFTER RETAINING WALL IS IN PLACE.

2. FOUNDATIONS

2.1. SPREAD FOOTINGS SHALL HAVE A DESIGN SOIL BEARING PRESSURE OF 2000 PSF.

2.2. ALL FOOTINGS SHALL BEAR ON UNDISTURBED SOIL AND SHALL BE LOWERED TO FIRM BEARING, IF SUITABLE SOIL IS NOT FOUND AT FOOTING ELEVATIONS INDICATED ON THESE DRAWINGS.

3 CONCRETE

3.1. MIXING AND PLACING OF ALL CONCRETE AND SELECTION OF MATERIALS SHALL BE IN ACCORDANCE WITH THE BUILDING CODE AND THE SPECIFICATIONS.

3.2. PROPORTIONS OF AGGREGATE TO CEMENT SHALL CREATE A DENSE, WORKABLE MIX WHICH CAN BE PLACED WITHOUT SEGREGATION OR EXCESS SURFACE WATER.

3.3. UNLESS SPECIFIED OTHERWISE, ALL TOLERANCES FOR CONCRETE SHALL CONFORM TO ACI 117.

3.4. ALL FORMWORK SHALL BE DESIGNED, ERECTED, SUPPORTED, BRACED AND MAINTAINED IN ACCORDANCE WITH ACI STANDARD 347.

3.5. WALLS AND SLABS MAY BE CORE DRILLED ONLY AS DETAILED OR AS APPROVED IN WRITING BY THE ENGINEER. VERIFY LOCATION OF REINFORCING BEFORE CORE DRILLING; NO REINFORCING SHALL BE CUT.

3.6. THE CONTRACTOR SHALL SUBMIT DRAWINGS SHOWING THE PROPOSED CONSTRUCTION AND CONTROL JOINTS FOR ALL CONCRETE, INCLUDING WALLS, SLABS ON GRADE, ETC., TO THE ENGINEER FOR REVIEW PRIOR TO PLACING ANY CONCRETE.

3.7. ALL CONCRETE WORK SHALL BE IN ACCORDANCE WITH THE CURRENT EDITIONS OF "BUILDING CODE REQUIREMENTS FOR REINFORCED CONCRETE, ACI-318".

3.8. CONCRETE MIXES SHALL BE AS APPROVED BY THE JOHNSON COUNTY CONCRETE BOARD AS MEETING DESIGNATIONS JCCB5K.

3.9. LAP ALL BARS AT SPLICES ACCORDING TO THE ACI CODE REQUIREMENTS BUT NOT LESS THAN 42 BAR DIAMETERS NOR LESS THAN 18 INCHES UNLESS OTHERWISE NOTED. ALL HORIZONTAL WALL BARS SHALL BE DEVELOPED AT CORNERS EITHER BY BENDING NOT LESS THAN 40 BAR DIAMETERS AROUND CORNERS OR WITH PROPERLY PLACED HOOKED AND LAPPED CORNER BARS.

3.10. ALL VERTICAL BARS SHALL LAP NOT LESS THAN 30 BAR DIAMETERS NOR LESS THAN 2'-6" UNLESS OTHERWISE NOTED.

3.11. EXPANSION JOINTS SHALL BE SPACED AT 60'-0" MAXIMUM CENTERS. REINFORCING BARS SHALL NOT BE CONTINUOUS THROUGH THE JOINT.

3.12. ALL CONCRETE WALLS SHALL BE PROPERLY BRACED AND HELD IN LINE UNTIL SUPPORTING SLABS OR FLOORS ARE IN PLACE.

3.13 ALL BAR STEEL SHALL BE PROPERLY SUPPORTED AND HELD ACCURATELY IN PLACE AS RECOMMENDED BY THE CONCRETE REINFORCING STEEL INSTITUTE, EXCEPT THAT MAXIMUM SPACING OF ANY BAR SUPPORT SHALL BE 3'-0". ALL TOP SLAB BARS SHALL BE SUPPORTED BY CONTINUOUS HIGH CHAIRS.

3.14 ALL DOWELS SHALL BE ACCURATELY PLACED AND SECURELY HELD IN POSITION BEFORE CONCRETE IS POURED. STICKING OF DOWELS INTO FRESH OR PARTIALLY HARDENED CONCRETE WILL NOT BE ACCEPTABLE.

3.15. ALL OPENINGS IN SLABS AND WALLS SHALL HAVE ADDITIONAL 2-#5X4'-0" DIAGONAL BARS AT EACH CORNER OF OPENING EXTENDING 2'-0" INTO ADJACENT EXCEPT WHERE SHOWN OTHERWISE.

4 REINFORCING STEEL

4.1. ALL CONCRETE IS REINFORCED CONCRETE UNLESS SPECIFICALLY INDICATED OTHERWISE. REINFORCE ALL CONCRETE NOT SPECIFICALLY DETAILED IN ACCORDANCE WITH TYPICAL DETAILS AND OTHER, SIMILAR CONDITIONS.

4.2. MILD REINFORCING STEEL SHALL CONFORM TO ASTM A615, GRADE 60.

4.3. DEFORMED BAR ANCHORS ARE TO BE RESISTANCE WELDED, CONFORMING TO ASTM A496, WITH A MINIMUM YIELD STRENGTH OF 70,000 PSI.

4.4. CONCRETE CAST AGAINST AND PERMANENTLY EXPOSED TO EARTH SHALL HAVE A MINIMUM COVER OF 3 INCHES.

4.5. CONCRETE EXPOSED TO EARTH WATER (RAW OR TREATED) OR WEATHER SHALL HAVE A MINIMUM COVER OF 1 1/2 INCHES FOR #5 BARS OR SMALLER, AND 2 INCHES FOR #6 BAR OR LARGER.

4.6. REINFORCING STEEL SHALL NOT BE TACK WELDED FOR ANY REASON. NO REINFORCING BARS SHALL BE WELDED (EXCEPT DEFORMED ANCHORS).

5. PRE ENGINEERED BRIDGE SPECIFICATIONS

5.1. THE PEDESTRIAN BRIDGE TO BE A LOW-PROFILE BRIDGE UTILIZING A PONY-TRUSS DESIGN, ALSO KNOWN AS A HALF-TRUSS DESIGN, U-FRAME STIFFNESS.

5.2. THE BRIDGE SHALL HAVE AN INSIDE NOMINAL DECK WIDTH OF 10 AND A CLEAR SPAN LENGTH OF 137 FEET.

5.3. THE STANDARD BRIDGE SHALL BE DESIGNED FOR A MINIMUM LIVELOAD OF 60 POUNDS PER SQUARE FOOT.

5.4. BRIDGE APPLICATIONS, SHALL BE DESIGNED IN ACCORDANCE WITH THE "SPECIFICATIONS FOR THE DESIGN, FABRICATION AND ERECTION OF STRUCTURAL STEEL FOR BUILDINGS BY THE AMERICAN INSTITUTE OF STEEL" (AISC) - LATEST EDITION.

5.5. WELDED TUBULAR STRUCTURAL DESIGN SHALL BE IN ACCORDANCE WITH THE STRUCTURAL WELDING CODE (ANSI/AWS D1.1--8)-CHAPTER 10. TUBULAR STRUCTURES.

5.6. RAILING HEIGHT SHALL BE 54 INCHES ABOVE THE DECK TO THE TOP OF TRUSS TOP CHORD.

5.7. ONE DIAGONAL STEEL MEMBER SHALL BE INSTALLED PER PANEL.

5.8. THE BRIDGE CAMBER AT CENTER OF BRIDGE SPAN SHALL BE 2 1/2% OF THE TOTAL BRIDGE SPAN. THE LOCALIZED DECK SLOPE SHALL NOT EXCEED 8.33%.

5.9. THE BRIDGE SHALL BE FABRICATED FROM HIGH STRENGTH, SELF-WEATHERING, LOW ALLOW, ATMOSPHERIC CORROSION RESISTANT ASTM A847 COLD-FORMED WELDED SQUARE AND RECTANGULAR TUBING, AND ASTM A588, ASTM A606, OR ASTM A242 PLATE AND STRUCTURAL SHAPES (FY=50,000 PSI)

5.10. FIELD SPLICES SHALL BE FULLY BOLTED WITH ASTM A325 TYPE 3 HIGH STRENGTH BOLTS IN ACCORDANCE WITH "SPECIFICATIONS FOR STRUCTURAL JOINTS USING ASTM A325 OR A490 BOLTS".

5.11. ALL WELDING SHALL UTILIZE E80 SERIES ELECTODES WHICH HAVE THE SAME WEATHERING CHARACTERISTICS AS CORROSION-RESISTANT STEEL.

5.12. ALL DECKING MATERIAL SHALL BE PRESSURE TREATED SOUTHERN YELLOW PINE SELECT STRUCTURAL PLANKS GRADED ACCORDING TO WCLB STANDARD GRADING. DECKING TO BE TREATED TO AWPA STANDARD P-5. PRESERVATIVES UTILIZED SHALL BE EITHER AMMONIACAL COPPER ARSENATE (CHEMONITE OR ACA) OR CHROMATED COPPER ARSENATE (CCA). DECKING SHALL BE TREATED TO A TOTAL ABSORPTION OF 0.40 POUNDS PER CUBIC FOOT OF WOOD, OR TO REFUSAL.

5.13. THE DECK PLANKS SHALL BE NOMINAL SIZE OF 3" X 12" FOR EQUESTRIAN AND 10,000 POUND VEHICLE LOADS.

5.14. SAFETY RAILS SHALL BE CONTINUOUS STEEL WITH A CLEAR OPENING OF 4 INCHES. CONTINUOUS 6 INCH HIGH TOE PLATE, 1 1/2 INCHES ABOVE THE DECK LEVEL.

5.15. NOMINAL 2" X 6" SOUTHERN YELLOW PINE RUB RAIL SHALL BE ON THE INSIDE OF THE BRIDGE, PLACED 32 INCHES ABOVE THE TOP OF THE DECK.

5.16. WORKMANSHIP, FABRICATION AND SHOP CONNECTIONS SHALL BE IN ACCORDANCE WITH AMERICAN ASSOCIATION OF STATE HIGHWAY AND TRANSPORTATION OFFICIALS SPECIFICATIONS (AASHTO).

5.17. WELDING OPERATORS SHALL BE EXPERIENCED IN THE TYPE OF WELDING REQUIRED TO ASSEMBLE THE PEDESTRIAN BRIDGE AND SHALL MEET ALL CITY REQUIREMENTS AND CERTIFICATIONS.

5.18. TO AID IN PROVIDING A UNIFORMLY "WEATHERED" APPEARANCE, ALL EXPOSED SURFACES OF STEEL SHALL BE BLAST CLEANED IN ACCORDANCE WITH STEEL STRUCTURES PAINTING COUNCIL SURFACE PREPARATION SPECIFICATIONS NO. 7 BRUSH-OFF BLAST CLEANING, SSPC-SP7 LATEST EDITION. EXPOSED SURFACES OF STEEL SHALL BE DEFINED AS THOSE SURFACES SEEN FROM THE DECK AND FROM OUTSIDE OF THE STRUCTURE. STRINGERS, FLOOR BEAMS, LOWER BRACE DIAGONALS AND THE INSIDE FACE OF THE TRUSS BELOW DECK AND BOTTOM FACE OF THE BOTTOM CHORD SHALL NOT BE BLASTED.

5.19. ALL CONCRETE FOR THE BRIDGE ABUTMENTS SHALL BE JCCB5K 5000 PSI.

6. STRUCTURAL STEEL TUBE HANDRAIL

6.1. HANDRAIL AT THE EAST AND WEST ENDS OF THE PEDESTRIAN BRIDGE SHALL BE GIVEN 1 SHOP COAT OF PRIMER AND THEN TWO COATS OF PAINT, THE COLOR TO BE DETERMINED BY THE OWNER.

6.2. THE HANDRAIL ON TOP OF THE 10" RETAINING WALLS SHALL BE HOT DIPPED GALVANIZED IN ACCORDANCE WITH ASTM 123.

SUMMARY OF QUANTITIES

Class I Excavation	610 Cu. Yds.
Class II Excavation	847 Cu. Yds.
Class AAA Concrete	583.8 Cu. Yds.
Reinforcing Steel	97490 Lbs.
Cast Iron	198 Lbs.
Removal of Existing Structure	Lump Sum

Note: Round bars of equivalent cross-sectional area may be substituted for ℄a bars.

GENERAL NOTES

Class AAA concrete shall be used throughout. All concrete shall be vibrated.

Bevel all exposed edges with a ¾" ∆ molding unless otherwise noted.

Construction Joints shall be made only at points indicated or as approved by the Engineer.

Falsework shall remain in place under each section of superstructure until the concrete has attained its design strength. The Handrail shall be constructed after falsework has been removed.

All parts of Cast Iron Drains accessible after erection shall receive one coat of tinted aluminum paint followed by one coat aluminum paint.

The Bridge Contractor shall remove existing structure (64' Steel Truss Span) after new has been constructed & opened to traffic.

Loading H20-44 (A.A.S.H.O. Specifications)

Basic Stresses: f'c = 3000 p.s.i. fs = 20,000 p.s.i. (Reinf.)

GENERAL NOTES

CONSTRUCTION SPECIFICATIONS: Kansas Department of Transportation, Standard Specifications for State Road and Bridge Construction, 1990, Metric Version, and Special Provisions.

DESIGN SPECIFICATIONS: AASHTO Standard Specifications for Highway Bridges, 1996 Edition, plus 1997 & 1998 interims.

BROKEN CONCRETE: Waste the broken concrete from the existing bridge on sites provided by the Contractor and approved by the Engineer. All necessary permits or agreements required to dispose of waste material will be the responsibility of the Contractor.

REMOVAL OF EXISTING CONCRETE: Removal of existing concrete is included in the bid item, "Removal of Existing Structures", Lump Sum. All materials removed from the existing structure shall become the property of the Contractor. Remove portions of the existing structure, to limits shown on the plans, to clear the new construction. Remove this material from the site.

CONCRETE: All concrete is bid as Concrete (Grade 30)(AE). Bevel all exposed edges of all concrete with a 20 mm triangular molding, except as otherwise noted on the plans. The Contractor may place the concrete rail continuously from one end of the bridge to the other.

EPOXY GROUTING: This item shall consist of drilling and grouting reinforcing steel into the existing concrete, where required by the Engineer, with an epoxy grout. Locate each hole with the aid of a pachometer to miss the existing reinforcing steel. Drill the holes to the specifications required by the grout manufacturer and in such a manner as not to damage adjacent concrete or bars. After the hole is drilled, remove all loose material by using a wire brush to free the dust from the side of the hole and then vacuuming to remove material and dust. Fill the hole 30% to 50% full of epoxy grout and insert the bar. Then fill the hole to 5 mm from the top of the hole. Follow the manufacturer's directions for mixing, application and curing. The tools, materials, labor and incidentals necessary to complete the work shall be subsidiary to Concrete (Grade 30)(AE).

REINFORCING STEEL: All reinforcing steel dimensions are to the centerline of bars unless otherwise noted. All new reinforcing steel shall conform to the requirements of ASTM A615M-96, Grade 420. All existing reinforcing steel shall remain in place unless otherwise noted or it is sufficiently deteriorated. Any reinforcing steel cut or damaged by the Contractor during concrete removal shall be replaced at no additional cost to the State.

CONSTRUCTION JOINTS: Construction Joints are optional with the Contractor. If used, place the construction Joints at locations approved by the Engineer.

DIMENSIONS: All dimensions shown on the design plans are horizontal dimensions unless otherwise noted.

QUANTITIES: Items not listed separately in the Summary of Quantities are subsidiary to other items in the proposal.

UTILITIES: There are no known utilities within the project limits. Contractor shall verify prior to starting construction.

STAGING AREA: The Contractor shall confine the storage of equipment and materials to an area in the southwest quadrant of the project. This storage area shall be approved by the City and shall be contained within temporary fencing. All areas damaged by the Contractor shall be restored to a condition equal to or better than that existing before damage occured. There shall be no separate payment for this work.

SUMMARY OF ESTIMATED QUANTITES

ITEM	UNITS	QUANTITY
CONCRETE (GRADE 30)(AE)	m^3	6.0
REINFORCING STEEL (GRADE 420)	kg	720
DRILLING AND GROUTING	Each	260
SIDEWALK CONSTRUCTION(100 mm)(AE)(REINF.)	m^2	113
BRIDGE METAL HANDRAIL (560 mm)	m	35.2
REMOVAL OF EXISTING STRUCTURES	Lump Sum	L.S.
TRAFFIC CONTROL	Lump Sum	L.S.
CONCRETE SAFETY BARRIER (TYPE I)(TEMPORARY)	m	42
MOBILIZATION	Lump Sum	L.S.
MOBILIZATION (DBE)	Lump Sum	L.S.
FLAGGER (SET)	Hour	1

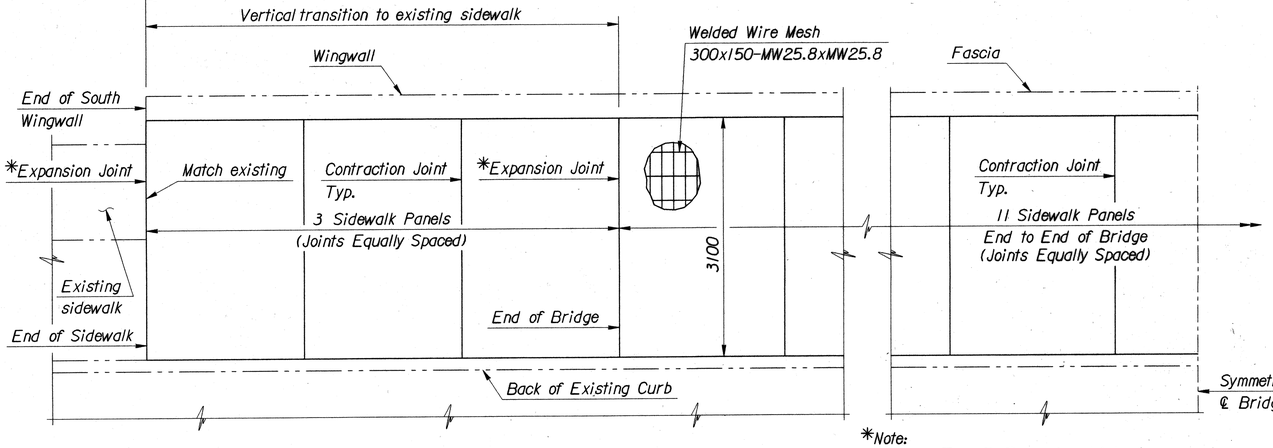
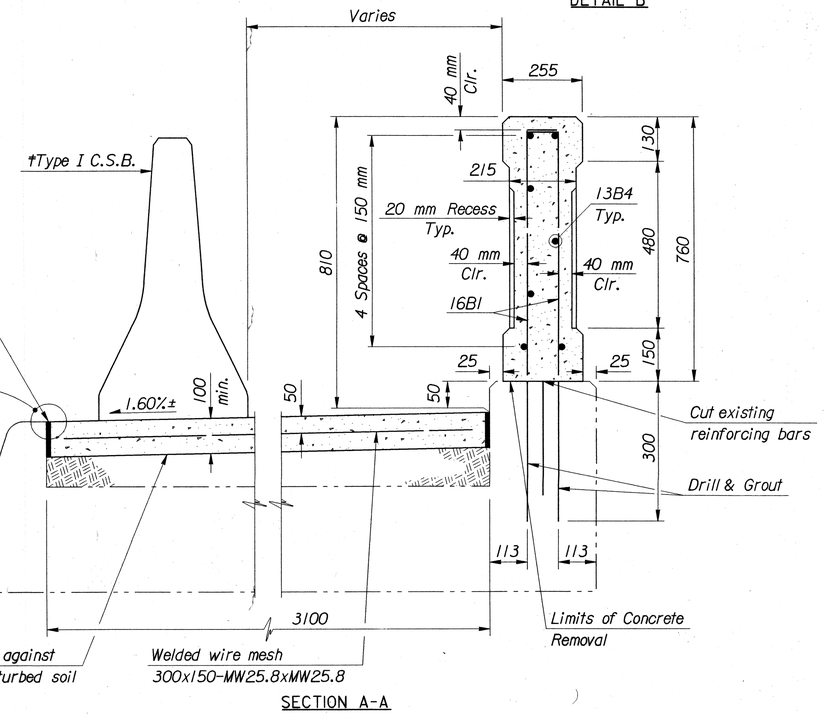
DETAIL B



WEST SIDEWALK PLAN

*Note:
13 mm Type B Expansion Joint
Filler with Silicone Joint Sealant.



SECTION A-A

Notes:

Remove the existing west sidewalk from end to end of wingwall. Saw cut the existing sidewalk at the ends of the wingwalls to neat lines. Repair damage to the existing sidewalk beyond the end of wingwalls at no cost to the project. Removal of existing sidewalk is included in the bid item "Removal of Existing Structures".

Sidewalk Construction will be paid for in m^2. Use Concrete (Grade 30)(AE) in the sidewalk. The excavation, tools, materials, labor and incidentals necessary to complete the work will be subsidiary to Sidewalk Construction. Limits of Sidewalk Construction extend from end to end of existing wingwalls and include a triangular portion between the end of the north wingwall and the parking lot entrance north of the bridge (see Plan on Sheet 2).

†Place Concrete Safety Barrier (Type I)(Temporary) at the location shown prior to the removal of the existing west concrete bridge railing. For the limits of the Type I C.S.B. see Sheet 2.

The length (36 170 mm) from end of the south wingwall to the end of the north wingwall along the west railing is based on field measurements. Verify this dimension by field measurement and submit such verification in writing to the Engineer prior to starting construction.

Bevel all exposed edges with a 20 mm triangular molding except as noted.
n.f. denotes near face.
f.f. denotes far face.
e.f. denotes each face.

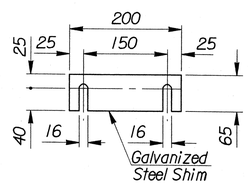
Provide 1-1.5 mm x 150 mm galvanized steel shim for each post, to be used as required.



SHIM DETAIL

Note:
Provide 1-1.5 mm x 200 mm galvanized steel shim for each post, to be used as required.

METAL HANDRAIL NOTES

Top rails shall be 64 mm Dia. standard steel pipe, Schedule 40 and shall conform to ASTM A53M, Type E or S, Grade B. Posts shall be 64x64x6.4 structural tubing and shall conform to ASTM A500, Grade B. Bottom rails, pickets and base plates shall conform to ASTM A709M (Grade 250).

Galvanize all rails, posts, pickets and base plates after fabrication. Galvanize in accordance with the requirements of the KDOT Standard Specifications.

Construct handrail according to Section 709 of the KDOT Standard Specifications.

Set rails parallel to the top of the concrete rail. Set all posts and pickets vertical in both planes of the handrail. Shims may be used between concrete and base plate of steel post.

Grind smooth all top and bottom rail-to-post welded connections. Field welding is not permitted. Submit shop drawings to the Engineer for approval prior to fabrication of the handrail.

Fabricate handrail in lengths to include a minimum of two and a maximum of three panels. Attach top rail members to at least two posts. Locate center of rail splices 525 mm from centerline of posts unless shown otherwise.

All material, labor, splices, shims, and installation shall be paid for under the bid item "Bridge Metal Handrail (560 mm)". Bid the handrail on a per meter basis measured from end to end of handrail.

Galvanize the stud concrete anchors and provide a minimum pullout strength of 35 kN based on 30 MPa concrete. Length of embedment into concrete shall conform to manufacturer's recommendations.

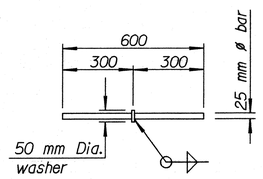
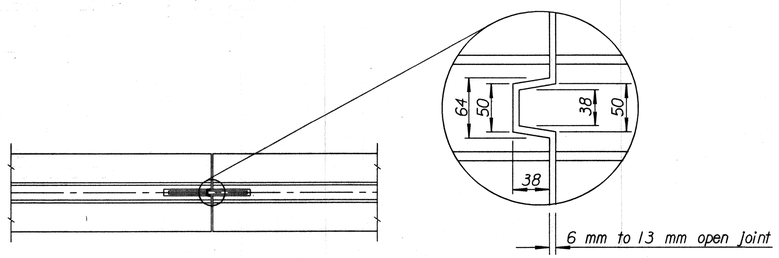
SECTION THRU CONNECTOR

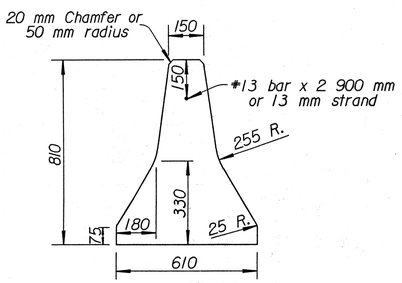
◆ For the convenience of the Contractor in replacing broken units, plate connectors as shown at the right may be used. At the Contractor's option, plate connectors may be used every 15 m in lieu of bar connectors. The Contractor shall use plates on both sides. When used, the Contractor may use either a 3 200 mm plate on the one side of the installed barrier unit or drill appropriate holes in the far side for dowels on the 1700 mm plate connector. This work is subsidiary to installing the barrier.



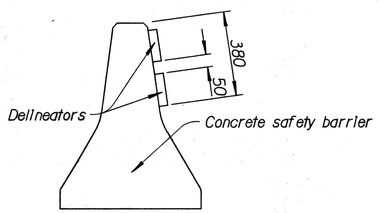
DETAIL "A"
(Showing 25 mm Φ bar & washer)



VIEW A-A



TYPICAL END SECTION



DELINEATOR DETAILS

MATERIAL: Use Concrete Grade 25 (AE) throughout. All structural steel shall be merchant grade. Reinforcing steel shall be Grade 300 or Grade 420 billet steel and shall meet the requirements of the KDOT Standard Specifications.

SECTION: The section furnished must generally comply with dimensions shown. Requests for minor variations in section geometry and attachments may be submitted to the Engineer for approval.

LIFTING SLOTS: Lifting slots shall be constructed where specified on the plans to facilitate the drainage of water after installation on the roadway. Approximate mass of one unit equals 1800 kg.

TEMPORARY CONCRETE SAFETY BARRIER: Furnishing and placing of all materials when required and all labor and equipment required to position the temporary barrier shall be included in the Contract unit price bid for "Concrete Safety Barrier (Type 1) (Temporary)". Any relocation of the barrier required for the project shall be paid in accordance with the KDOT Special Provisions under the bid item "Concrete Safety Barrier (Type 1) (Temp.- Relocate)". Unless otherwise noted on the Plans the Temporary Safety Barrier shall become the property of the Contractor and shall be removed from the site upon acceptance of the completed project.

SURFACE PREPARATION: Temporary concrete barriers shall be placed on either a concrete or bituminous surface. All loose dirt and sand shall be removed from the roadway surface just prior to placement of the safety barrier. Temporary barriers shall not be placed directly on soil or gravel.

SIGNING: For sign spacing, details of other traffic control devices and reference notes, see other sheets.

DELINEATION: Delineators shall be spaced on 30 m centers, except through curves having 580 m radius or less where they shall be spaced on 6 m centers.

All delineators shall be one of the following: Stimsonite 965 Y or W, Astro-Optics Model JD-1 or 2, Duraflex Model Flexx 2020, or an approved equivalent to those listed.

The delineation shall be mounted on the side of the Temporary Concrete Safety Barrier with two delineators at each location. Each delineator shall have a minimum height-to-width ratio of 1.75, and a minimum reflective surface area of 4 500 mm². The delineators shall be affixed to the Temporary Concrete Safety Barrier as recommended by the manufacturer.

Delineators shall be attached to bridge rail or other structures in construction zones when roadway is narrowed and traffic is adjacent to the structure. The method and location of placement shall be similar to temporary barrier delineation. All work and materials required for this installation shall be subsidiary to the bid item "Concrete Safety Barrier (Type ◆) (Temporary)".

When traffic flow is in one direction, the delineators shall be yellow when used on the left, and white when used on the right. When traffic flow is in both directions, delineators shall be placed back-to-back, and shall correspond to the color of the edge line.

The work and materials required for the installation of delineators shall be subsidiary to the Temporary Safety Barrier bid item.

TEMPORARY BARRIERS: Barriers constructed to the details of this drawing shall not be used in permanent installations.

◆ Type shall be either Type I or Type IV.

7	KANSAS	46N-0156-01	2000	6	9

GENERAL NOTES

1. CHANNELIZING DEVICES: "DEVICES" INCLUDES BUT IS NOT LIMITED TO BARRICADES, BARRIERS, CONES, DRUMS AND VERTICAL PANELS.

   (A) THE MAXIMUM SPACING BETWEEN DEVICES IN THE TAPER SHOULD NOT EXCEED A DISTANCE IN METERS EQUAL TO 0.3 TIMES THE SPEED LIMIT (IN MPH) PRIOR TO WORK.

   (B) THE SPACING BETWEEN DEVICES IN THE WORK ZONE SHOULD NOT EXCEED A DISTANCE IN METERS OF 0.6 TIMES THE POSTED SPEED (MPH).

   (C) WHERE EXISTING CONDITIONS WARRANT, THE ENGINEER MAY REQUIRE A DECREASE IN THE SPACING STIPULATED ABOVE. WHEN TRAFFIC CONTROL IS BID LUMP SUM, ADDITIONAL DEVICES AND WARNING LIGHTS WILL BE PAID FOR AS EXTRA WORK.

   (D) TRAFFIC CONES MAY BE UTILIZED AS CHANNELIZING DEVICES FOR DAY-TIME TRAFFIC CONTROL OPERATIONS. THE ENGINEER MAY REQUIRE THAT CONES BE SUPPLEMENTED BY OTHER TRAFFIC CONTROL DEVICES IN CERTAIN SITUATIONS SUCH AS OPEN TRENCHES.

2. COVERING OF SIGNS NOT IN USE:

   WHEN NO WORK IS IN PROGRESS NOR IS ANY EXPECTED TO BE FOR AN EXTENDED PERIOD OF TIME, AND THE ROADWAY IS UNRESTRICTED TO THE TRAVELING PUBLIC, TRAFFIC CONTROL SIGNS SHALL BE REMOVED OR COMPLETELY COVERED WITH ADEQUATE OPAQUE WATERPROOF MATERIAL. TAPE SHALL NOT BE APPLIED TO THE FACE OF A SIGN.

3. CLEAR ZONE:

   WHENEVER PRACTICAL, ALL CONSTRUCTION EQUIPMENT, MATERIALS, AND DEBRIS SHALL BE STORED OUT OF THE CLEAR ZONE. WHERE THIS CANNOT BE ACHIEVED, THE CONTRACTOR SHALL PLACE APPROPRIATE SIGNS AND/OR BARRICADES AS DESIGNATED BY THE ENGINEER. TRAFFIC CONTROL DEVICES NEEDED FOR THIS CONDITION SHALL BE CONSIDERED SUBSIDIARY TO OTHER BID ITEMS.

4. MAINTENANCE:

   THE CONTRACTOR SHALL MAINTAIN ALL SIGNS AND DEVICES IN THEIR PROPER POSITION AND CLEAN AND/OR REPLACE ANY DAMAGED OR ILLEGIBLE SIGN OR DEVICE AS DIRECTED BY THE ENGINEER.

5. TAPER FORMULAS:

   $L = WS$ FOR SPEEDS OF 45 MPH OR MORE

   $L = WS^2/60$ FOR SPEEDS OF 40 MPH OR LESS

   WHERE: L = MINIMUM LENGTH OF TAPER IN METERS
   S = NUMERICAL VALUE OF POSTED SPEED PRIOR TO WORK IN MPH
   W = WIDTH OF OFFSET IN METERS

6. PAVEMENT MARKINGS:

   (A) TYPE I TAPE IS TO BE APPLIED TO A FINAL SURFACE AS A TEMPORARY MARKING WHEN THE PATTERN OF THE PERMANENT MARKINGS WILL BE DIFFERENT THAN THE TEMPORARY MARKING.

   TYPE II TAPE IS TO BE APPLIED TO A TEMPORARY SURFACE THAT IS TO BE REMOVED OR COVERED BY FUTURE CONSTRUCTION. TYPE II TAPE IS ALSO TO BE APPLIED TO A FINAL SURFACE WHERE IT IS KNOWN THERE WILL BE PERMANENT MARKINGS PLACED IN THE SAME PATTERN AS THE TEMPORARY TYPE II TAPE.

   (B) ALL CONFLICTING PAVEMENT MARKINGS SHALL BE REMOVED AND ALL TRANSITION TAPERS, CROSSOVERS, AND EDGE LINES ALONG CHANNELIZING DEVICES SHALL BE MARKED WITH SOLID 100 mm WIDE PAVEMENT MARKING TAPE WHEN THE WORK WILL OCCUPY A LOCATION MORE THAN THREE DAYS.

7. TEMPORARY AND POST MOUNTED SIGNS:

   TRAFFIC CONTROL PLANS THAT ARE ANTICIPATED TO REMAIN IN PLACE DURING DAYLIGHT HOURS ONLY ARE CONSIDERED "TEMPORARY". TEMPORARY SIGNS SHALL BE MOUNTED AT A MINIMUM HEIGHT OF 300 mm. TRAFFIC CONTROL PLANS OF LONGER DURATION WILL REQUIRE THAT ALL SIGNS BE POST MOUNTED AT A MINIMUM HEIGHT OF 2.1 m.

8. EXISTING SIGNS:

   IF EXISTING SIGNS THAT ARE TO REMAIN (OR THAT ARE TO BE REMOVED AND RESET) INTERFERE WITH CONSTRUCTION WORK, THE CONTRACTOR SHALL REMOVE, STORE, AND RESET THE SIGNS. THIS SHALL BE SUBSIDIARY TO OTHER TRAFFIC CONTROL BID ITEMS.

9. CONFLICTING SIGNS:

   ALL PERMANENT AND TEMPORARY SIGNING WHICH IS IN CONFLICT WITH THE TRAFFIC CONTROL PLAN SHALL BE REMOVED OR COVERED.

10. MINIMUM LANE WIDTHS:

    LANE WIDTHS SHALL BE A MINIMUM OF 3.4 m (MEASURED BETWEEN CENTERLINES OF PAVEMENT MARKINGS), OR AS SHOWN ON THE PLANS, OR AS DIRECTED BY THE ENGINEER. A LANE WIDTH LESS THAN 3.4 m MAY REQUIRE RESTRICTED ROADWAY WIDTH SIGNING.

11. FLAGGER:

    A MINIMUM OF ONE FLAGGER SHALL BE STATIONED WITHIN EACH INTERSTATE WORK AREA WHERE WORK IS ADJACENT TO TRAFFIC.

12. BARRICADES:

    TYPE III BARRICADES PLACED ACROSS A ROADWAY SHALL BE SUITABLY DISTRIBUTED ACROSS THE ROADWAY TO EFFECTIVELY CLOSE THE ROADWAY. WHERE PROVISION IS MADE FOR ACCESS BY AUTHORIZED VEHICLES, THE BARRICADES SHALL CLOSE THE ROAD AT THE END OF THE WORK DAY. WHEN ACCESS MUST BE ALLOWED FOR LOCAL TRAFFIC, THE TYPE III BARRICADES SHOULD BE STAGGERED.

SIGN SPACING (IN METERS):

	A	B	C
URBAN (40 MPH OR LOWER)	60	60	60
URBAN (45 MPH OR HIGHER)	115	115	115
RURAL	150	150	150
EXPRESSWAY/FREEWAY	300	525	800

IN NO CASE SHALL THE SPACING BETWEEN SIGNS BE LESS THAN 30 m.

BUFFER SPACE:

SPEED (MPH)	20	25	30	35	40	45	50	55	60	65	70
LENGTH (m)	10	15	25	35	50	65	85	100	125	150	175

NEITHER WORK ACTIVITY NOR STORAGE OF EQUIPMENT, VEHICLES, OR MATERIAL SHOULD OCCUR IN THE BUFFER SPACE. WHEN A PROTECTION VEHICLE IS PLACED IN ADVANCE OF THE WORK SPACE, ONLY THE SPACE UPSTREAM OF THE VEHICLE CONSTITUTES THE BUFFER SPACE.

IF TEMPORARY CONCRETE SAFETY BARRIER IS USED TO SEPARATE APPROACHING TRAFFIC FROM THE WORK ACTIVITY, THE BARRIER SHALL BE CONSIDERED PART OF THE WORK AREA. A FULL LANE WIDTH SHOULD BE AVAILABLE THROUGHOUT THE LENGTH OF THE BUFFER SPACE. FOR EXAMPLE:

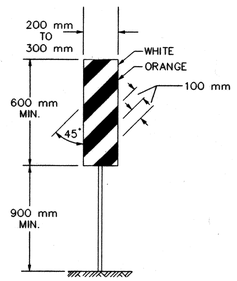
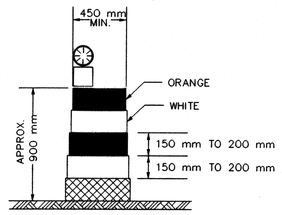
ARROW DISPLAY ELEMENTS SHALL BE CAPABLE OF A MINIMUM 50 PERCENT DIMMING FROM THEIR FULL-RATED LAMP VOLTAGE. FULL LAMP VOLTAGE SHOULD BE USED FOR DAY AND DIMMED MODE SHALL BE USED FOR NIGHT.

VERTICAL PANEL

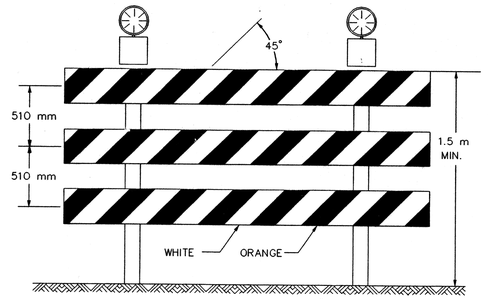


THE ENTIRE AREA OF VERTICAL PANELS SHALL BE FULLY REFLECTORIZED WITH TYPE II HIGH PERFORMANCE RETROREFLECTIVE SHEETING. VERTICAL PANELS USED ON ROADWAYS WITH A SPEED LIMIT OF 45 MPH OR GREATER SHALL HAVE A MINIMUM OF 0.175 SQ m OF RETROREFLECTIVE AREA FACING TRAFFIC.

NON-METALLIC REFLECTORIZED DRUM WITH LIGHT

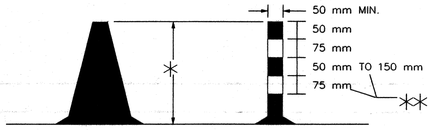


DRUMS SHALL BE REFLECTORIZED FULL CIRCUMFERENCE WITH AT LEAST TWO ORANGE AND TWO WHITE 150 TO 200 mm WIDE STRIPES OF TYPE II HIGH PERFORMANCE RETROREFLECTIVE SHEETING. ADDITIONAL ORANGE AND WHITE STRIPES MAY BE NON-REFLECTIVE. IF THERE ARE NON-REFLECTIVE SPACES BETWEEN ADJACENT STRIPES, THEY SHALL BE NO MORE THAN 50 mm WIDE.



TYPE III BARRICADE WITH LIGHTS

A MINIMUM OF TWO TYPE A LIGHTS SHALL BE USED AT EACH LOCATION WHERE A TYPE III BARRICADE OR BARRICADES ARE USED. A LIGHT SHALL BE MOUNTED ON THE OUTSIDE CORNER OF THE END BARRICADES WHEN MORE THAN ONE IS USED.



ORANGE CONES TUBULAR MARKERS

* CONES AND TUBULAR MARKERS SHALL HAVE A MINIMUM HEIGHT OF 710 mm WHEN USED ON 45 MPH OR GREATER ROADWAYS. THE MINIMUM HEIGHT MAY BE REDUCED TO 450 mm ON ROADWAYS OF 40 MPH AND LOWER.

** FOR 710 mm TUBULAR MARKERS

TRAFFIC CONES MAY BE USED FOR DAYTIME OPERATIONS ONLY. IN CERTAIN SITUATIONS, SUCH AS OPEN TRENCHES, THE ENGINEER MAY REQUIRE THAT CONES BE SUPPLEMENTED BY OTHER TRAFFIC CONTROL DEVICES.

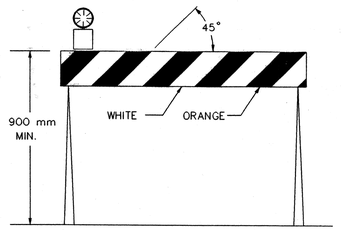
WARNING LIGHTS

WARNING LIGHTS SHALL COMPLY WITH THE CURRENT ITE PURCHASE SPECIFICATIONS FOR FLASHING AND STEADY BURN WARNING LIGHTS. THE LENS SHALL BE A MINIMUM OF 175 mm IN DIAMETER AND BE MOUNTED AT A MINIMUM HEIGHT OF 750 mm.

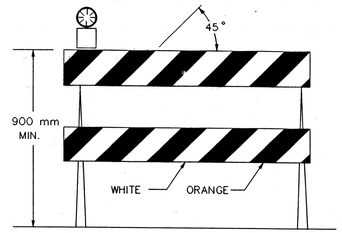
WARNING LIGHTS USED ON INDIVIDUAL CHANNELIZING DEVICES SHALL BE TYPE A FLASHING. THOSE USED ON DEVICES PLACED IN SERIES SHALL BE TYPE C STEADY BURN, WITH THE EXCEPTION THAT WARNING LIGHTS ARE NOT TO BE USED ON REFLECTORIZED DRUMS PLACED IN SERIES.

TYPE B HIGH INTENSITY LIGHTS ARE TO BE USED ON CONSTRUCTION WARNING SIGNS AS DIRECTED BY THE ENGINEER.

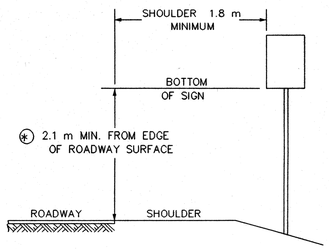
TYPE A LOW INTENSITY FLASHING WARNING LIGHTS AND TYPE C STEADY BURN WARNING LIGHTS SHALL BE MAINTAINED SO AS TO BE CAPABLE OF BEING VISIBLE ON A CLEAR NIGHT FROM A DISTANCE OF 1000 m. TYPE B HIGH INTENSITY FLASHING WARNING LIGHTS SHALL BE MAINTAINED SO AS TO BE CAPABLE OF BEING VISIBLE ON A SUNNY DAY FROM A DISTANCE OF 300 m WHEN VIEWED WITHOUT THE SUN DIRECTLY ON OR BEHIND THE DEVICE.



TYPE I BARRICADE WITH LIGHT



TYPE II BARRICADE WITH LIGHT



SUPPORTS USED FOR MOUNTING SIGNS OR DEVICES FOR TEMPORARY CONDITIONS SHALL BE CONSTRUCTED TO YIELD UPON IMPACT. ADDITIONAL SUPPORTS MAY BE PLACED ON THE BACK SIDE OF SIGNS IN THE FORM OF BRACING FOR RESISTING WIND CURRENTS. GUY WIRES AND TIE-DOWNS WILL NOT BE ALLOWED.

SIGNS MOUNTED ON TYPE III BARRICADES SHOULD NOT COVER MORE THAN 50 PERCENT OF THE TOP TWO RAILS OR 33 PERCENT OF THE TOTAL AREA OF THE THREE RAILS.

* THE HEIGHT TO THE BOTTOM OF A SECONDARY SIGN MOUNTED BELOW ANOTHER SIGN MAY BE 2.0 m.

NOTE:

ALL TRAFFIC CONTROL DEVICES, THEIR INSTALLATION AND MAINTENANCE SHALL COMPLY WITH THE REQUIREMENTS OF THE MANUAL ON UNIFORM TRAFFIC CONTROL DEVICES FOR STREETS AND HIGHWAYS. WHENEVER THIS STANDARD CONFLICTS WITH THE MANUAL, THIS STANDARD SHALL GOVERN.

CHANNELIZING DEVICES SHALL BE PLACED FOR OPTIMUM VISIBILITY, NORMALLY AT RIGHT ANGLES TO THE TRAFFIC FLOW.

CHANNELIZING DEVICES PLACED ALONG SHOULDER EDGES OR IN DROPOFFS SHALL HAVE A MINIMUM OF 600 mm FROM THE TOP OF THE CHANNELIZING DEVICE TO THE TOP OF THE PAVEMENT.

WHERE PERMANENT OBJECT MARKERS ARE NOT ALREADY IN PLACE, ORANGE AND WHITE VERTICAL PANELS SHALL BE ERECTED TO DELINEATE EXPOSED BRIDGE ENDS.

THE FIRST MODULE OF EACH INERTIAL BARRIER SYSTEM SHALL HAVE A MINIMUM OF 0.175 SQ m OF TYPE II HIGH PERFORMANCE ORANGE RETROREFLECTIVE SHEETING FACING TRAFFIC. EITHER A VERTICALLY RECTANGULAR OR DIAMOND SHAPE MAY BE USED.

BARRICADES

	TYPE I	TYPE II	TYPE III
WIDTH OF RAIL	200 mm MIN-300 mm MAX	200 mm MIN-300 mm MAX	200 mm MIN-300 mm MAX
LENGTH OF RAIL	600 mm MIN	600 mm MIN	1200 mm MIN
WIDTH OF STRIPES	150 mm	150 mm	150 mm
HEIGHT	900 mm MIN	900 mm MIN	1500 mm MIN
NO. OF REFL. RAIL FACES	2 (ONE EACH DIRECTION)	4 (TWO EACH DIRECTION)	*

* 3 IF FACING TRAFFIC IN ONE DIRECTION, 6 IF BOTH DIRECTIONS.

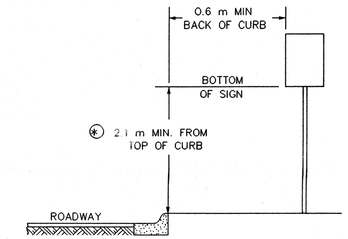
FOR WOODEN BARRICADES, NOMINAL LUMBER DIMENSIONS WILL BE SATISFACTORY.

FOR RAILS LESS THAN 900 mm LONG, 100 mm WIDE STRIPES MAY BE USED.

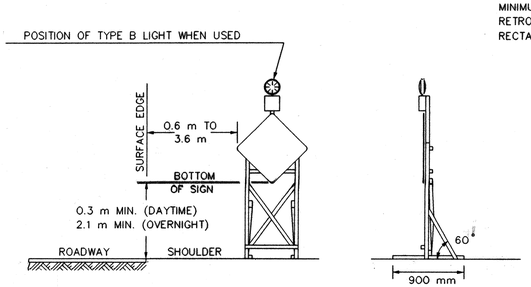
THE ENTIRE AREA OF BARRICADE RAILS SHALL BE FULLY REFLECTORIZED WITH TYPE II HIGH PERFORMANCE RETROREFLECTIVE SHEETING.

BARRICADES USED ON ROADWAYS WITH SPEED LIMITS OF 45 MPH OR MORE SHALL HAVE A MINIMUM OF 0.175 SQ m OF RETROREFLECTIVE AREA FACING TRAFFIC.

THE STRIPES SHALL SLOPE DOWNWARD TO THE TRAFFIC SIDE FOR CHANNELIZATION, AND TOWARD THE CENTER OF THE ROADWAY AT ROAD CLOSURES.



HEIGHT AND LATERAL DIMENSIONS FOR POST MOUNTED SIGNS (ALL SIGNS LEFT IN PLACE OVERNIGHT OR LONGER)



HEIGHT AND LATERAL DIMENSIONS FOR SIGNS MOUNTED ON SKIDS OR OTHER MOVABLE MOUNTS

TWO (2) 450 mm x 450 mm FLUORESCENT RED-ORANGE FLAGS ARE TO BE ATTACHED IN THE POSITION SHOWN ON SIGNS (B) (C) (D) (E) (F) AND (U). THE FLAGS AND STAFFS ARE TO BE ATTACHED IN SUCH A MANNER THAT THE SIGN FACE WILL NOT BE OBSCURED. THE FLAGS MAY BE EITHER A CLOTH OR VINYL MATERIAL. THE FLAGS SHALL BE SUBSIDIARY TO THE WARNING SIGN BID ITEMS.

AHEAD, ~~1500 FT OR 1MPH~~

AHEAD, 1000 FT, 1500 FT OR 1/2 MILE

RIGHT or LEFT

SPEED TO BE DETERMINED BY THE ENGINEER.

NOTE:

ALL DEVICES SHALL COMPLY WITH THE CURRENT EDITION OF THE MANUAL ON UNIFORM TRAFIC CONTROL DEVICES FOR STREETS AND HIGHWAYS. WHENEVER THIS STANDARD CONFLICTS WITH THE MANUAL, THIS STANDARD SHALL GOVERN.

EXCEPT FOR M-SIGNS USED IN ROUTE MARKER ASSEMBLIES AND AS OTHERWISE NOTED, ALL SIGNS SHALL BE FULLY RETROREFLECTORIZED WITH TYPE II HIGH PERFORMANCE SHEETING.

FOR ALL PROJECTS LET AFTER JULY 1, 1996, ALL SIGNS NOW REQUIRING TYPE II HIGH PERFORMANCE SHEETING SHALL BE REPLACED WITH SIGNS RETROFLECTORIZED WITH FLUORESCENT ORANGE PRISMATIC GRADE RETROFLECTIVE SHEETING.

NOTE:

SIGN (R) IS TO BE USED IF THE PROJECT EXCEEDS 3.2 km. THE LENGTH SHOWN "*" SHALL BE TO THE NEAREST WHOLE MILE.

FOR SPEEDS OF 30 MPH OR LESS, SIGN (E) WILL BE A WI-3. FOR SPEEDS ABOVE 30 MPH, THE WI-4 SIGN WILL BE USED.

WHEN USED ON INTERSTATE, FREEWAY OR EXPRESSWAY ROUTES, SIGNS (K) (L) (M) AND (O) ARE TO BE 1200 mm x 1500 mm, THE R2-5d IS TO BE 1200 mm x 600 mm, AND SIGN (Z) IS TO BE 1200 mm x 600 mm.

SIGNS (K) AND (L) SHOULD BE USED ONLY IF THE ENGINEER DETERMINES THAT A REDUCED SPEED IS REQUIRED THROUGHOUT THE PROJECT.

SIGN (K) SHALL BE INSTALLED THROUGHOUT THE LENGTH OF THE PROJECT AS DIRECTED BY THE ENGINEER, AND BE PAID FOR AT THE "EACH PER DAY" BID FOR THE SIZE OF SIGN USED.

WHERE THE ROAD IS OPEN BEYOND THE POINT OF CLOSURE, EITHER THE RII-3, ROAD CLOSED ( ) MILES AHEAD LOCAL TRAFFIC ONLY SIGN, OR THE RII-4, ROAD CLOSED TO THRU TRAFFIC SIGN, SHOULD BE SUBSTITUTED FOR SIGN (P).

SIGN (S) SHOULD BE PLACED 150 m FROM THE END OF THE ACTUAL WORK AREA, AND NOT NECESSARILY AT THE EXTREME LIMITS OF THE PROJECT.

SIGN (J) IS TO BE ELIMINATED IF THE ADVISORY SPEED IS WITHIN 5 MPH OF THE SPEED LIMIT.

NOTE:

SEE SHEET #3 FOR SECTION 1.
SEE SHEET #3 FOR ELEVATION A-A.

CONSTRUCTION NOTES:

1. RIP-RAP TO BE HEAVY STONE RIP-RAP (1/4 TON).
2. GROUT FOR HEAVY STONE RIP-RAP SHALL BE KCMMB, 4K WITH APPROVED ADMIXTURE TO CREATE AN 8" MAXIMUM SLUMP (5% - 8% AIR).
3. CONCRETE TOE WALL AND BRACE WALL TO BE 12" THICK KCMMB, 4K WITH APPROVED ADMIXTURE TO CREATE A 5" MAXIMUM SLUMP (5% - 8% AIR).
4. REINFORCING STEEL TO BE GRADE 60 EPOXY COATED BARS WITH 18" MINIMUM LAP.
5. ALL GRADING OF EXISTING GRAVEL BAR AND PLACEMENT OF HEAVY STONE RIP-RAP SHALL BE INCLUDED IN THE BID ITEM "HEAVY STONE RIP-RAP".
6. THE CONTRACTOR SHALL HIRE AN INDEPENDENT LABORATORY ACCEPTABLE TO THE OWNER AND TAKE FOUR (4) CONCRETE CYLINDERS FOR TESTING TOE WALL AND BRACE WALL CONCRETE. ONE CYLINDER SHALL BE TESTED AT 7 DAYS, ONE AT 14 DAYS, AND TWO AT 28 DAYS. TESTING RESULTS SHALL BE SENT TO THE CONTRACTOR AND OWNER AFTER EACH TEST. THE COST FOR THE TESTING SHALL BE SUBSIDIARY.
7. PRIOR TO PLACING MATERIAL IN ANY GIVEN CELL, STREAM FLOW WATER SHALL BE DIVERTED FROM THE AREA BEING MODIFIED TO SOUTH CELL AND WATER SHALL BE REMOVED FROM THE CELL BEING MODIFIED. THE CONTRACTOR SHALL DEVELOP A PLAN FOR DIVERTING STREAM WATER DURING CONSTRUCTION.
8. ALL DIMENSIONS SHOWN IN PLANS ARE APPROXIMATE AND SHALL BE VERIFIED BY THE CONTRACTOR. THE CONTRACTOR SHALL VISIT THE SITE AND MAKE ALL NECESSARY MEASUREMENTS BEFORE SUBMITTING A BID FOR THIS PROJECT.

(SEE PHOTOGRAPH #7)

ESTIMATED QUANTITIES		
ITEM	MEASURE	ESTIMATED QUANTITY
TRAFFIC CONTROL	L.S.	1
AREA PREPARED FOR PATCHING (PARTIAL DEPTH)	SQ. YDS.	~~4.5~~ 3.7
DECK OVERLAY REPAIR	SQ. YDS.	~~17.5~~ 18.51
CURB REPLACEMENT	L.F.	152
CLEAN BRICK PAVERS	SQ. FT.	720
CLEAN AND COAT BRIDGE BARRIER RAIL	SQ. FT.	910
ASPHALT REPAIR (BY OTHERS)	TONS	10

CONSTRUCTION AND GENERAL NOTES:

1. CONCRETE: Concrete for bridge Deck Overlay Repair, Curb Replacement and Area Prepared for Patching (Partial Depth), shall be KCMMB, 4K with 3" maximum slump (5%-8% Air).

2. REINFORCING STEEL: Reinforcing steel shall be ASTM A615, Grade 60 (epoxy coated). Drilling and epoxy grouting (4" minimum embedment) of vertical curb dowel bars shall be SUBSIDIARY to bid item "Curb Replacement".

3. AREA PREPARED FOR PATCHING: This item shall consist of removing unsound concrete and bituminous patches from the bridge deck, cleaning reinforcing bars and filling the removed patched areas with concrete. Quantity shown is an estimate of the areas involved. The exact areas shall be determined by tapping, before, during and after chipping operation to assure that all unsound concrete has been removed. See KDOT Specifications. Areas to be patched will be determined by the Engineer. After unsound material is removed, the area shall be high pressure air cleaned and the surface shall be coated with ~~WELD-CRETE~~ BONDALL bonding agent prior to placing new concrete.

4. DECK OVERLAY REPAIR: The unsound deck overlay (2" +/-) shall be removed as indicated on the plans. The exact area will be determined by the Engineer. After removal of the unsound concrete overlay, the area shall be high pressure air cleaned and the surface shall be coated with ~~WELD-CRETE~~ BONDALL bonding agent prior to placing new concrete.

5. CURB REPLACEMENT: The existing concrete curb for the length of the bridge deck shall be removed down to the top of the existing bridge deck. Saw cut a straight line 2" deep through the existing (2" +/-) overlay at the edge of the existing curb. Remove existing horizontal and vertical reinforcement. Install new curb dowel bars at 16" centers (max.) by drilling and epoxying into existing bridge deck with a minimum embedment of 4" Clean the curb repair area with high pressure air and apply ~~WELD-CRETE~~ BONDALL bonding agent prior to placing new curb. All material, labor and equipment shall be included in bid item "Curb Replacement".

6. CLEAN AND COAT BRIDGE BARRIER RAIL: The inside face and top of the existing bridge barrier rails on both sides of the bridge shall be sand blast cleaned and shall be coated with white SUPER THOROSEAL per manufacturers recommendations. The existing metal handrail shall be protected to prevent damage to the painted surfaces. Contractor shall repaint, at no cost to the owner, any damaged handrail areas with paint approved by the owner.

7. ASPHALT REPAIR: The deteriorated aphalt at the ends of concrete bridge shall be removed and replaced as indicated on the plans. The replacement asphalt shall be Superpave (By City).

8. TRAFFIC CONTROL: Contractor shall submit traffic control plan to Engineer for approval prior to construction. Two (2) lanes of two (2) way traffic shall be maintained across the Merriam Drive Bridge during construction. Sidewalks shall be kept open for pedestrian/bicycle traffic. Access to businesses shall be provided during construction.

Date: 5/29/2013 Time: 7:51:20 AM File Name: P:\12.042.01\Drawings\Sheets\07-photos.dgn

1. MUTCD COMPLIANCE:

ALL TEMPORARY TRAFFIC CONTROL DEVICES AND THEIR INSTALLATION AND MAINTENANCE SHALL COMPLY WITH THE LATEST EDITION OF THE MANUAL ON UNIFORM TRAFFIC CONTROL DEVICES (MUTCD) FOR STREETS AND HIGHWAYS WHICH HAS BEEN ADOPTED BY THE SECRETARY OF TRANSPORTATION. WHENEVER THE TEMPORARY TRAFFIC CONTROL STANDARDS CONFLICT WITH THE MUTCD, THE STANDARDS SHALL GOVERN.

2. DESIGN SPEED:

THOSE ITEMS DELEGATED TO TEMPORARY TRAFFIC CONTROL SHOULD BE DESIGNED AND INSTALLED USING THE POSTED/LEGAL SPEED OF THE ROADWAY PRIOR TO WORK STARTING.

3. CLEAR ZONE:

ALL CONSTRUCTION EQUIPMENT (INCLUDING VEHICLES), MATERIALS, AND DEBRIS SHALL BE STORED OUT OF THE CLEAR ZONE. WHERE THIS CANNOT BE ACHIEVED, THE CONTRACTOR SHALL PLACE APPROPRIATE SIGNS, OBJECT IDENTIFIERS, AND/OR BARRICADES AS DESIGNATED BY THE ENGINEER. TEMPORARY TRAFFIC CONTROL DEVICES NEEDED FOR THIS CONDITION SHALL BE CONSIDERED SUBSIDIARY TO OTHER BID ITEMS.

4. MINIMUM LANE WIDTHS:

LANE WIDTHS SHALL BE A MINIMUM OF 11' (MEASURED BETWEEN CENTERLINES OF PAVEMENT MARKINGS) OR AS SHOWN ON THE PLANS, OR AS DIRECTED BY THE ENGINEER. A LANE WIDTH LESS THAN 11' MAY REQUIRE RESTRICTED ROADWAY WIDTH SIGNING.

5. FLAGGER:

A MINIMUM OF ONE FLAGGER SHALL BE STATIONED WITHIN EACH MULTI-LANE ROADWAY ACTIVITY AREA WHERE WORK IS IN A CLOSED LANE ADJACENT TO TRAFFIC AND NOT SEPARATED BY A CONCRETE SAFETY BARRIER SYSTEM.

6. PAVEMENT MARKING:

WHEN THE WORK WILL OCCUPY A LOCATION MORE THAN THREE DAYS, ALL CONFLICTING PAVEMENT MARKINGS SHALL BE REMOVED OR MASKED AND ALL TRANSITION TAPERS, CROSSOVERS, AND EDGE LINES ALONG CHANNELIZING DEVICES SHALL BE MARKED WITH SOLID 4" WIDE PAVEMENT MARKING.

7. FIRST MODULE OF IBS:

THE FIRST MODULE OF EACH INERTIAL BARRIER SYSTEM (IBS) SHALL HAVE A MINIMUM OF 2 SQ. FT. OF FLUORESCENT ORANGE ASTM TYPE IV SHEETING FACING TRAFFIC. EITHER A VERTICAL RECTANGLE OR DIAMOND SHAPE MAY BE USED.

8. PEDESTRIAN / BICYCLE SAFETY:

WORK ZONE SIGNS SHALL NOT INHIBIT PEDESTRIAN AND BICYCLE TRAFFIC ON SIDEWALKS OR OTHER AREAS DESIGNATED FOR PEDESTRIAN OR BICYCLE USE.

CONSIDERATION SHOULD BE MADE TO SEPARATE PEDESTRIAN AND BICYCLE MOVEMENTS FROM BOTH WORK SITE ACTIVITY AND VEHICULAR TRAFFIC. UNLESS A REASONABLE SAFE ROUTE THAT DOES NOT INVOLVE CROSSING THE ROADWAY CAN BE PROVIDED, PEDESTRIANS AND BICYCLISTS SHOULD BE APPROPRIATELY DIRECTED WITH ADVANCE SIGNING THAT ENCOURAGES THEM TO CROSS TO THE OPPOSITE SIDE OF THE ROADWAY. IN URBAN AND SUBURBAN AREAS WITH HIGH VEHICULAR TRAFFIC VOLUMES, THESE SIGNS SHOULD BE PLACED AT INTERSECTIONS (RATHER THAN MIDBLOCK LOCATIONS) SO THAT PEDESTRIANS AND BICYCLISTS ARE NOT CONFRONTED WITH MIDBLOCK WORK SITES THAT WILL INDUCE THEM TO ATTEMPT SKIRTING THE WORK SITE OR MAKING A MIDBLOCK CROSSING.

WHEN EXISTING PEDESTRIAN FACILITIES ARE DISRUPTED, CLOSED, OR RELOCATED, THE TEMPORARY FACILITIES SHALL BE DETECTABLE AND INCLUDE ACCESSIBILITY FEATURES CONSISTENT WITH THE FEATURES PRESENT IN THE EXISTING PEDESTRIAN FACILITY.

9. CHANGED STOP CONDITIONS:

ATTACH TWO FLAGS AND A RED TYPE "B" HIGH INTENSITY WARNING LIGHT TO ANY STOP SIGN THAT CREATES A NEW STOP CONDITION OR MOVES THE STOP CONDITION TO A NEW LOCATION. LEAVE FLAGS AND LIGHTS IN PLACE FOR AT LEAST THE FIRST 30 DAYS. INSTALL W3-1 (SYMBOLIC STOP AHEAD) SIGN IN ADVANCE OF STOP SIGN IF STOP SIGN IS NOT VISIBLE FOR A MINIMUM OF DISTANCE 'A' (SEE CHART ON TE710) OR IF STOP CONDITION IS MOVED TO LESS THAN DISTANCE 'A' FROM AN EXISTING STOP AHEAD SIGN.

10. LUMP SUM BIDDING:

WHEN TRAFFIC CONTROL IS BID LUMP SUM, ADDITIONAL DEVICES WILL BE PAID FOR AS EXTRA WORK.

11. NIGHTTIME LIGHTING:

WHEN NIGHTTIME WORK IS REQUIRED, FLOODLIGHTS SHOULD BE USED TO ILLUMINATE FLAGGER STATIONS, EQUIPMENT CROSSINGS, AND OTHER AREAS WHERE EXISTING LIGHTING IS NOT ADEQUATE FOR THE WORK TO BE PERFORMED SAFELY.

IN NO CASE SHALL FLOODLIGHTS BE PERMITTED TO CREATE A DISABLING GLARE FOR THE DRIVER. THE ADEQUACY OF THE FLOODLIGHT PLACEMENT AND ELIMINATION OF POTENTIAL GLARE SHOULD BE CHECKED BY DRIVING THROUGH THE PROJECT.

12. NCHRP REPORT 350 CRASHWORTHY REQUIREMENTS:

TRAFFIC CONTROL DEVICES SHALL MEET THE EVALUATION CRITERIA IN NCHRP REPORT 350 AS SUPPLEMENTED BY FHWA MEMORANDUM "IDENTIFYING ACCEPTABLE HIGHWAY SAFETY FEATURES," DATED JULY 25, 1997. AVAILABLE ON THE INTERNET AT http://safety.fhwa.dot.gov/roadway_dept/road_hardware/nchrp_350.htm

ANY DEVICE NOT ADDRESSED BY THE TE STANDARDS MAY BE APPROVED ON A CASE BY CASE BASIS BY THE ENGINEER. THE DEVICE SHALL BE ACCOMPANIED BY AND INSTALLED ACCORDING TO NCHRP REPORT 350.

THE CONTRACTOR SHALL:

1) PROVIDE TO THE ENGINEER A COPY OF THE MANUFACTURER'S SELF-CERTIFICATION THAT ANY CATEGORY 1 (i.e. - PLASTIC CONICAL DELINEATORS, TUBULAR MARKERS, DRUMS WITHOUT ATTACHMENTS) AND CATEGORY 2 (i.e. - PORTABLE SIGN STANDS (WITH SIGNS), TYPE II AND III BARRICADES, AND VERTICAL PANELS) DEVICES USED ON THE PROJECT ARE NCHRP REPORT 350 COMPLIANT.

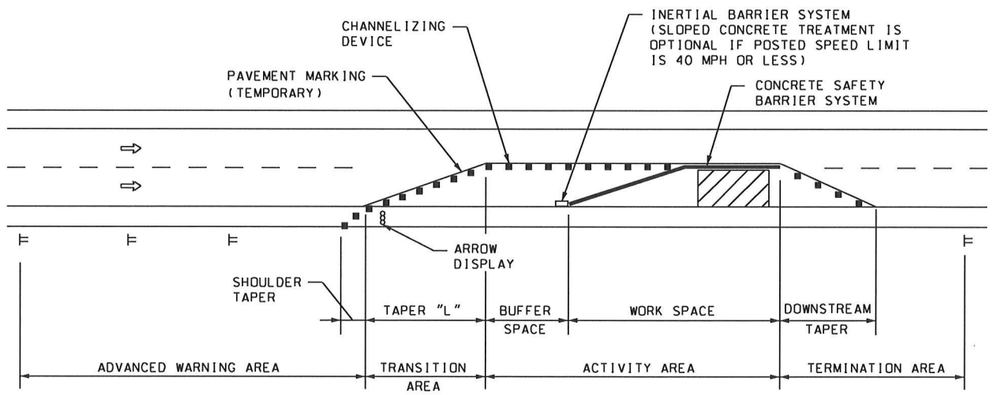
2) PROVIDE TO THE ENGINEER A COPY OF THE ENTIRE FHWA NCHRP REPORT 350 ACCEPTANCE LETTER (WZ-xxx) FOR ANY CATEGORY 2 DEVICE (i.e. - PORTABLE SIGN STANDS (WITH SIGNS), TYPE II AND III BARRICADES, AND VERTICAL PANELS) USED ON THE PROJECT. WORK ZONE FHWA NCHRP REPORT 350 ACCEPTANCE LETTERS (WZ-xxx) ARE AVAILABLE ON THE INTERNET AT:
http://safety.fhwa.dot.gov/roadway_dept/road_hardware/listing.cfm?code=workzone

3) CERTIFY THAT THE TRUCK MOUNTED ATTENUATORS (TMA'S) (WHICH ARE DEFINED AS CATEGORY 3 DEVICES BY THE FHWA MEMORANDUM) WERE PURCHASED PRIOR TO OCTOBER 1, 1998, AND INCLUDE A COPY OF THE ENTIRE FHWA ACCEPTANCE LETTER STATING THAT THE TMA'S ARE NCHRP REPORT 230 COMPLIANT; OR IF THE DEVICES WERE PURCHASED AFTER OCTOBER 1, 1998, INCLUDE A COPY OF THE ENTIRE FHWA'S ACCEPTANCE LETTER STATING THAT THE TMA'S ARE NCHRP REPORT 350 COMPLIANT.

ALL CATEGORY 1 & 2 DEVICES SHALL BE NCHRP REPORT 350 COMPLIANT. TMA'S, PURCHASED PRIOR TO OCTOBER 1, 1998, MAY BE USED UNTIL THE END OF THEIR SERVICEABLE LIVES.

13. TYPE "A" LOW INTENSITY WARNING LIGHTS:

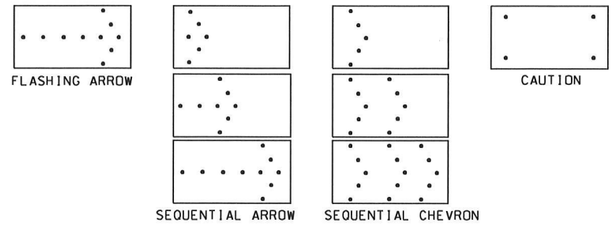
A TYPE "A" LOW INTENSITY WARNING LIGHT IS AN L.E.D. BI-DIRECTIONAL FLASHING WORK ZONE WARNING LIGHT.



TYPICAL WORK ZONE COMPONENTS

NOTE:
REFER TO STD. TE702 FOR TAPER "L" FORMULA.

ARROW DISPLAYS



ARROW DISPLAY ELEMENTS SHALL BE CAPABLE OF A MINIMUM 50 PERCENT DIMMING FROM THEIR FULL-RATED LAMP VOLTAGE. FULL LAMP VOLTAGE SHOULD BE USED DURING THE DAY AND DIMMED MODE SHALL BE USED AT NIGHT. FOR SHOULDER WORK, ROADSIDE WORK NEAR THE SHOULDER, BLOCKING THE SHOULDER, OR FOR TEMPORARY CLOSING ONE LANE ON A TWO-LANE, TWO-WAY ROADWAY, AN ARROW PANEL SHALL BE USED ONLY IN THE CAUTION MODE.

BUFFER SPACE

SPEED (MPH) ✱	*20*	*25*	*30*	*35*	*40*	*45*	*50*	*55*	*60*	*65*	*70*
LENGTH (ft)	*115*	*155*	*200*	*250*	*305*	*360*	*425*	*495*	*570*	*645*	*730*

NEITHER WORK ACTIVITY NOR STORAGE OF EQUIPMENT, VEHICLES, OR MATERIAL SHOULD OCCUR IN THE BUFFER SPACE. WHEN A PROTECTION VEHICLE IS PLACED IN ADVANCE OF THE WORK SPACE, ONLY THE SPACE UPSTREAM OF THE VEHICLE CONSTITUTES THE BUFFER SPACE.

✱ POSTED SPEED PRIOR TO WORK STARTING

IF TEMPORARY CONCRETE SAFETY BARRIER SYSTEM IS USED TO SEPARATE APPROACHING TRAFFIC FROM THE WORK SPACE, THE BARRIER SYSTEM SHALL BE CONSIDERED PART OF THE ACTIVITY AREA. A FULL LANE WIDTH SHOULD BE AVAILABLE THROUGHOUT THE LENGTH OF THE BUFFER SPACE. SEE TYPICAL WORK ZONE COMPONENTS.

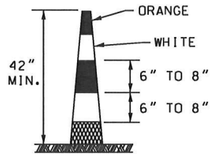
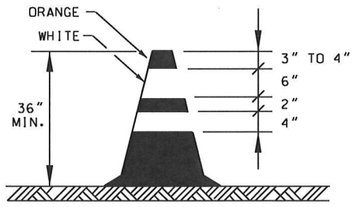
DRUM



CONICAL
DELINEATOR

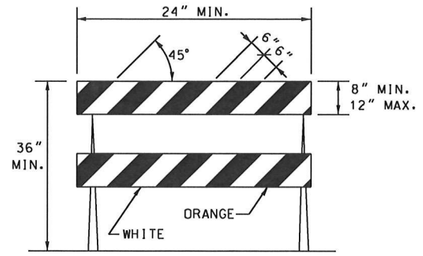
DRUMS AND CONICAL DELINEATORS SHALL HAVE AT LEAST TWO ORANGE AND TWO WHITE 6" TO 8" WIDE RETROREFLECTIVE STRIPES. ADDITIONAL STRIPES MAY BE NON-RETROREFLECTIVE. IF THERE ARE NON-RETROREFLECTIVE SPACES BETWEEN ADJACENT STRIPES, THEY SHALL BE NO MORE THAN 3" WIDE.

ALL RETROREFLECTIVE STRIPES ON DRUMS SHALL BE ASTM TYPE III SHEETING. THE WHITE STRIPES ON CONICAL DELINEATORS SHALL BE ASTM TYPE III SHEETING. ORANGE STRIPES ON ALL CONICAL DELINEATORS SHALL BE FLUORESCENT ORANGE ASTM TYPE IV SHEETING.



TRAFFIC CONE

TRAFFIC CONES MAY BE USED AS CHANNELIZING DEVICES FOR DAYTIME OPERATIONS ONLY. THEY WILL NOT BE PAID FOR SEPARATELY, BUT WILL BE SUBSIDIARY TO OTHER TRAFFIC CONTROL BID ITEMS. THE ENGINEER MAY REQUIRE THAT TRAFFIC CONES BE SUPPLEMENTED BY OTHER TRAFFIC CONTROL DEVICES IN CERTAIN SITUATIONS.

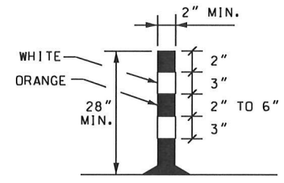


TYPE II BARRICADE

FOR RAILS LESS THAN 36" LONG, 4" WIDE STRIPES MAY BE USED.

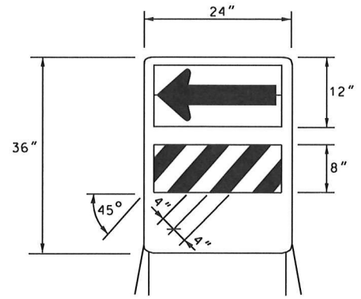
THE ENTIRE AREA OF BARRICADE RAILS, BOTH FRONT AND BACK, SHALL BE ASTM TYPE III SHEETING.

THE STRIPES SHALL SLOPE DOWNWARD TO THE TRAFFIC SIDE FOR CHANNELIZATION.



TUBULAR MARKER

THE TWO WHITE RETROREFLECTIVE STRIPES SHALL BE ASTM TYPE III SHEETING.

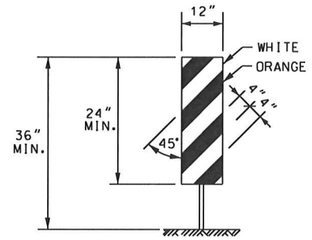


DIRECTION INDICATOR BARRICADE

THE ARROW PANEL SHALL BE BLACK ON FLUORESCENT ORANGE ASTM TYPE IV SHEETING. THE STRIPES SHALL BE ORANGE AND WHITE ASTM TYPE III SHEETING SLOPING DOWNWARD IN THE DIRECTION TRAFFIC IS TO PASS.

THE DIRECTION INDICATOR BARRICADE SHALL BE USED IN SERIES TO DIRECT THE MOTORIST INTO THE INTENDED LANE OF TRAVEL.

THE ARROW PANEL SHOULD NOT BE VISIBLE TO OPPOSING TRAFFIC.



VERTICAL PANEL

THE ENTIRE AREA OF VERTICAL PANELS, BOTH FRONT AND BACK, SHALL HAVE ASTM TYPE III SHEETING. THE STRIPES SHALL SLOPE DOWNWARD TO THE TRAFFIC SIDE FOR CHANNELIZATION.

ITEM / LOCATION		CROSS-OVERS	SHOOFLY DIVERSIONS	TANGENTS	TAPERS	RAMPS	HEAD TO HEAD	OBJECT IDENTIFIER	
PORTABLE									
	DRUMS	YES	YES	YES	YES	YES	(1)	YES	
	CONICAL DELINEATORS	YES	YES	YES	YES	YES	(1)	YES

	VERTICAL PANELS	(3)	(3)	(3)	(3)	(3)	(3)	YES	

(1) Not allowed on centerline delineation along freeways or expressways.

(2) The stripes shall slope downward to the traffic side for channelization.

(3) May be used upon the approval of the Engineer.

TAPER FORMULAS:

L = WS FOR SPEEDS OF 45 MPH OR MORE

$L = WS^2/60$ FOR SPEEDS OF 40 MPH OR LESS

WHERE: L = MINIMUM LENGTH OF TAPER IN FEET
S = NUMERICAL VALUE OF POSTED SPEED PRIOR TO WORK STARTING IN MPH
W = WIDTH OF OFFSET IN FEET

CHANNELIZER PLACEMENT:

(A) THE SPACING BETWEEN DEVICES IN TRANSITION AREA (TAPER) SHOULD NOT EXCEED A DISTANCE IN FEET EQUAL TO 1/2 THE POSTED SPEED LIMIT IN MPH PRIOR TO WORK STARTING.

(B) THE SPACING BETWEEN DEVICES IN THE ADVANCED WARNING AREA AND THE ACTIVITY AREA SHOULD NOT EXCEED A DISTANCE IN FEET EQUAL TO TWO TIMES THE POSTED SPEED LIMIT IN MPH PRIOR TO WORK STARTING.

(C) CHANNELIZING DEVICES SHALL BE PLACED FOR OPTIMUM VISABILITY, NORMALLY AT RIGHT ANGLES TO THE TRAFFIC FLOW.

(D) CHANNELIZING DEVICES PLACED ALONG SHOULDER EDGES OR IN DROPOFFS SHALL HAVE A MINIMUM OF 24" FROM THE TOP OF THE CHANNELIZING DEVICE TO THE TOP OF THE PAVEMENT.

GENERAL NOTES

1. MAINTENANCE:

THE CONTRACTOR SHALL MAINTAIN ALL SIGNS AND DEVICES IN AN UPRIGHT POSITION. THE CONTRACTOR SHALL CLEAN OR REPLACE ANY DAMAGED OR ILLEGIBLE SIGN OR DEVICE AS DIRECTED BY THE ENGINEER.

2. EXISTING SIGNS:

IF EXISTING SIGNS THAT ARE TO REMAIN (WHETHER DENOTED ON THE PLANS OR NOT) INTERFERE WITH CONSTRUCTION WORK, THE CONTRACTOR SHALL REMOVE, STORE, AND RESET THE SIGNS. THIS SHALL BE SUBSIDIARY TO OTHER TRAFFIC CONTROL BID ITEMS. SIGNING DAMAGED BY THE CONTRACTOR SHALL BE REPLACED AT THE CONTRACTOR'S EXPENSE.

3. CONFLICTING SIGNS, SIGNS NOT IN USE, AND TRAFFIC SIGNALS:

SIGNS AND TRAFFIC SIGNALS THAT ARE IN CONFLICT WITH THE TRAFFIC CONTROL PLAN OR DO NOT APPLY TO THE TRAFFIC OPERATIONS SHALL BE IMMEDIATELY REMOVED, TURNED SO NOT VISIBLE TO TRAFFIC FROM ANY DIRECTION, OR COMPLETELY COVERED WITH ADEQUATE OPAQUE WATERPROOF MATERIAL. TAPE SHALL NOT BE APPLIED TO THE FACE OF THE SIGN.

4. PORTABLE AND POST MOUNTED SIGNS:

TEMPORARY TRAFFIC CONTROL SIGNS THAT ARE ANTICIPATED TO REMAIN IN PLACE FOR 3 DAYS OR LESS ARE CONSIDERED "PORTABLE." PORTABLE SIGNS SHALL BE MOUNTED ON AN APPROVED SUPPORT AT A MINIMUM HEIGHT OF 12" ABOVE THE TRAVELED WAY. TRAFFIC CONTROL SIGNS IN PLACE FOR OVER 3 DAYS ARE REQUIRED TO BE MOUNTED ON APPROVED POSTS. A MINIMUM OF 42" OF THE APPROVED POST MUST BE BELOW THE GROUND SURFACE WITH ADEQUATE BACKFILL AND COMPACTION. ALL POSTS AT MINIMUM SHALL EXTEND TO THE TOP EDGE OF THE SIGN AND NO GREATER THAN 6" ABOVE THE SIGN.

WHEN THE SIGN WIDTH IS EQUAL TO OR GREATER THAN 9', THREE OR MORE WOOD POSTS MAY BE USED WITH A MINIMUM OF 4' BETWEEN THE CENTERLINE OF EACH POST. ALL SIGNS LESS THAN 9' IN WIDTH SHALL USE A MAXIMUM OF TWO WOOD POSTS.

"ROLL-UP" SIGNS MAY BE USED FOR PORTABLE WARNING SIGNS. THEY MUST BE FLUORESCENT ORANGE ASTM TYPE IV SIGNS OF OPAQUE MATERIAL. MESH SIGNS ARE NOT ALLOWED.

5. SHEETING:

ALL ORANGE SIGNS SHALL HAVE FLUORESCENT ORANGE ASTM TYPE IV SHEETING. ALL OTHER SIGNS SHALL HAVE ASTM TYPE III SHEETING OF STANDARD COLORS.

6. SIGNS INVOLVING SPEEDS:

THE W3-5 (SPEED REDUCTION) SHOULD BE USED ONLY IF THE ENGINEER DETERMINES THAT A REDUCED SPEED IS REQUIRED ON THE PROJECT.

THE KM4-20 (WORK ZONE) PLAQUE SHALL BE PLACED ABOVE ALL SPEED LIMIT SIGNS, (R2-1), EXISTING AND TEMPORARY. MOUNT THE WORK ZONE PLAQUES TO THE POST. DO NOT OVERLAP THE R2-1 AND KM4-20 SIGNS.

FOR SPEEDS OF 30 MPH OR LESS, THE W1-1(TURN) OR W1-3(REVERSE TURN) SHOULD BE USED. FOR SPEEDS OF 35 MPH OR MORE, THE W1-2(CURVE) OR W1-4(REVERSE CURVE) SHOULD BE USED. THE W13-1(MPH) IS TO BE ELIMINATED IF THE ADVISORY SPEED IS WITHIN 5 MPH OF THE SPEED LIMIT.

7. SIGNS CONTROLLING WORK ZONE:

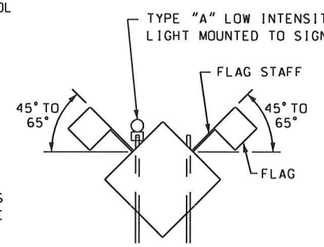
THE KG20-2(END ROAD WORK) SHOULD BE PLACED 500' FROM THE END OF THE ACTUAL WORK SPACE, NOT NECESSARILY AT THE EXTREME LIMITS OF THE PROJECT. THE KG20-2 SHOULD BE MOUNTED ON TWO POSTS. THE KG20-2 MAY BE MOUNTED ON ONE POST IF IN URBAN AREAS WHERE UTILITIES ARE A PROBLEM AND WIND LOADS ARE NOT AN ISSUE.

WHERE TWO WORK ZONES ARE LESS THAN 1 MILE APART IN RURAL AREAS OR $^{1}/_{4}$ MILE APART IN URBAN AREAS, THE KG20-2(END ROAD WORK) FOR THE FIRST WORK ZONE AND THE W20-1(ROAD WORK) FOR THE SECOND WORK ZONE SHOULD BE ELIMINATED.

8. WARNING LIGHTS ON SIGNS:

TYPE "A" LOW INTENSITY WARNING LIGHTS SHOULD BE USED WITH ALL CONSTRUCTION ACTION WARNING SIGNS AND SHALL NOT BE USED ON SIGNS MOUNTED LESS THAN 5' HIGH ON TEMPORARY SUPPORTS. ON ALL OTHER CONSTRUCTION WARNING SIGNS, TYPE "A" LOW INTENSITY WARNING LIGHTS ARE TO BE USED AS DIRECTED BY THE ENGINEER.

TYPE "A" LOW INTENSITY WARNING LIGHTS SHALL BE MAINTAINED SO AS TO BE CAPABLE OF BEING VISIBLE ON A CLEAR NIGHT FROM A DISTANCE OF 3000 FT. IF A TYPE "A" LOW INTENSITY WARNING LIGHT HAS A SEPARATE BATTERY CASE, THE BATTERY CASE SHALL BE MOUNTED NO HIGHER THAN 12" ABOVE THE GROUND AND MOUNTED BEHIND THE SIGN POST. A TYPE "A" LOW INTENSITY WARNING LIGHT WHERE THE LENS AND BATTERY ARE ONE UNIT SHALL BE MOUNTED ON THE TEMPORARY SIGN POST NEAREST TO THE TRAVELED WAY. FLAGS SHALL NOT INTERFERE WITH THE VISABILITY OF THE TYPE "A" LOW INTENSITY WARNING LIGHT.



TWO (2) 18" x 18" FLUORESCENT RED-ORANGE FLAGS SHALL BE ATTACHED (IN THE POSITION SHOWN) ON THE W20-2(DETOUR), W1-1(TURN), W1-2(CURVE), W1-3(REVERSE TURN), W1-4(REVERSE CURVE), W3-3(SIGNAL AHEAD), W4-2(LANE REDUCTION), W20-4(ONE LANE ROAD), W20-5(LANE CLOSED), W20-7A(FLAGGER), AND W3-4 (BE PREPARED TO STOP) SIGNS AND ANY OTHER ACTION SIGNS AS SHOWN ON THE PLANS OR DIRECTED BY THE ENGINEER. THE FLAGS AND STAFFS ARE TO BE ATTACHED IN SUCH A MANNER THAT THE SIGN WILL NOT BE OBSCURED. THE FLAGS MAY BE EITHER A CLOTH OR VINYL MATERIAL. THE FLAGS SHALL BE SUBSIDIARY TO THE CONSTRUCTION SIGN BID ITEMS.

9. AFAD'S

FLAGGER SHALL BE A PERSON WHO PROVIDES TEMPORARY TRAFFIC CONTROL.

FLAGGER STATIONS SHALL BE LOCATED SUCH THAT APPROACHING ROAD USERS WILL HAVE SUFFICIENT DISTANCE TO STOP AT AN INTENDED STOPPING POINT.

THE FIVE CATEGORIES OF WORK DURATION AND THEIR TIME AT A LOCATION SHALL BE:

A. LONG-TERM STATIONARY IS WORK THAT OCCUPIES A LOCATION FOR MORE THAN 3 DAYS.
B. INTERMEDIATE-TERM STATIONARY IS WORK THAT OCCUPIES A LOCATION MORE THAN ONE DAYLIGHT PERIOD UP TO 3 DAYS, OR NIGHTTIME WORK LASTING LONGER THAN 1 HOUR.
C. SHORT-TERM STATIONARY IS DAYTIME WORK THAT OCCUPIES A LOCATION FOR MORE THAN 1 HOUR WITHIN A SINGLE DAYLIGHT PERIOD.
D. SHORT DURATION IS WORK THAT OCCUPIES A LOCATION UP TO 1 HOUR.
E. MOBILE IS WORK THAT MOVES INTERMITTENTLY OR CONTINUOUSLY.

ONE LANE, TWO-WAY VEHICULAR TRAFFIC FLOW REQUIRES AN ALL-RED INTERVAL OF SUFFICIENT DURATION FOR ROAD USERS TO CLEAR THE PORTION OF THE TEMPORARY TRAFFIC CONTROL ZONE CONTROLLED BY THE TRAFFIC CONTROL SIGNALS. SAFEGUARDS SHALL BE INCORPORATED TO AVOID THE POSSIBILITY OF CONFLICTING SIGNAL INDICATIONS AT EACH END OF THE TEMPORARY TRAFFIC CONTROL ZONE.

SIGN LAYOUT INFORMATION

MILEAGE TO BE DETERMINED BY THE ENGINEER.

W8-11

COLORS:
LEGAND - BLACK (NON-REFLECTIVE)
BACKGROUND - ORANGE (REFLECTIVE)

W8-9a

COLORS:
LEGAND - BLACK (NON-REFLECTIVE)
BACKGROUND - ORANGE (REFLECTIVE)

THIS SIGN IS TO BE INSTALLED FOR CONDITIONS OF HEIGHT DIFFERENTIAL BETWEEN ADJACENT LANES OVER ONE (1) INCH. IT IS TO BE PLACED AT EACH INTERSECTING CROSSROAD, MAJOR TRAFFIC GENERATOR, OR AT APPROXIMATELY ONE-HALF (1/2) MILE INTERVALS. THE SIGNS ARE TO BE REMOVED OR COVERED WHEN NOT APPLICABLE.

MINIMUM ADVANCE WARNING SIGN SPACING (IN FEET):

	A	B	C
URBAN (40 MPH OR LOWER)	100	100	100
URBAN (45 MPH OR HIGHER)	350	350	350
RURAL (55 MPH OR LOWER)	500	500	500
RURAL (60 MPH OR HIGHER)	750	750	750
EXPRESSWAY/FREEWAY	1000	1500	2640

THE MINIMUM SPACING BETWEEN SIGNS SHALL BE NO LESS THAN 100', UNLESS DIRECTED BY THE ENGINEER.

THE SPACING BETWEEN ANY SIGNS MAY BE INCREASED BEYOND THE MINIMUM VALUES IN THE TABLE ABOVE AS APPROVED BY THE ENGINEER IN ORDER TO MAXIMIZE VISIBILITY.

APPENDIX F – HAZARDOUS AND TOXIC WASTE

This page was intentionally left blank for duplex printing.

ENVIRONMENTAL LAWS AND REGULATIONS

Various Federal and State legislation regulates the proper use, disposal, and clean up of hazardous materials and waste.

Resource Conservation and Recovery Act (RCRA)

Passed by Congress in 1976, this law gives the Environmental Protection Agency the authority to regulate hazardous waste disposal. This is accomplished by tracking the hazardous waste from its generation to its disposal. In 1984, there were several amendments made to this act, called the Hazardous and Solid Waste Act (HSWA). The amendments were enacted to include underground storage tank regulation, all releases of hazardous waste to the environment, and mandates for corrective action at hazardous waste facilities.

Toxic Substance Control Act (TSCA)

Also enacted by Congress in 1976, this law deals with all chemicals produced or imported into the United States. It requires that the chemical be adequately tested for toxicity prior to its commercial release to the public. In 1979, this act was amended to include the prohibition of the manufacture and distribution polychlorinated biphenyls (PCBs). PCBs are required to be labeled and disposed of properly. In the Statutes of Kansas, K.A.R. 28-55-5 states that PCB treatment, storage and disposal facilities shall comply with all applicable requirements of 40 CFR 761 subpart D, as in effect on November 1, 1986 and 40 CFR 264 subparts B, C, D, G and H, as in effect on November 1, 1986.

Comprehensive Environmental Response, Compensation and Liability Act (CERCLA)

Nicknamed Superfund, this law was enacted to start a trust fund for the payment of remediation at abandoned hazardous waste sites. This law was passed in 1980. The issue of abandoned or uncontrolled sites has grown through the years. The EPA manages the National Priority List, which lists certain CERCLA sites of the highest priority. By law, the State of Kansas also maintains a registry list of all abandoned and uncontrolled hazardous waste sites within the state. Superfund Amendments and Reauthorization Act (SARA) amended CERCLA in 1984. The amendments included more state and community involvement in the remediation process, increased focus on human health problems posed by contaminated sites, selection of remedies that permanently cleaned the site, and consideration of standards and other requirements in State and other Federal laws and regulations.

Federal Facility Compliance Act (FFCA)

In 1992, Congress passed the Federal Facility Act, which requires the Department of Energy (DOE) to develop and submit Site Treatment Plans for the development of capacity and technologies for treating mixed waste. All facilities that the DOE stores or generates these wastes must have such a plan. It also requires schedules for bringing new treatment facilities into operation.

State Regulations

The State of Kansas provides regulations for the use, management, and disposal of hazardous waste. These regulations are found in Article 31 on Hazardous Waste Management with additional statutes on Public Health in Chapter 65 and Hazardous Waste in Regulation Article 34. Environmental Use Controls are mentioned in K.S.A 65-1, 221 to 65-1, 235 and gives the state authority to assist existing programs to help address environmental contamination in a cost-effective manner and restrict the use of land where controls exist. It also empowers the State to enforce the regulations, defines hazardous waste, and controls the management, treatment, and disposal of hazardous waste. Statute Article 34 Solid Waste and Regulation Article 55 establishes criteria for facilities that handle and dispose of PCB waste. Article 28 contains regulations pertaining to the protection of surface waters and the water supply from environmental contamination and establishes water quality standards.

RECORDS SEARCH

A records search for potential contaminated sites along the reach of Turkey Creek addressed by this DDR, was performed in 2009, and updated in 2015 and again in 2023. The records search consisted reviewing various Federal and State of Kansas databased for past and present environmental activities and enforcement actions at properties adjacent to the creek. The information sources reviewed as part of this records search included:

- USEPA Enviromapper - GIS database identifying Superfund sites, sites were hazardous releases have occurred, and facilities regulated by the USEPA that handle materials designated as hazardous waste.

- USEPA CERCLIS Database - The Comprehensive Environmental Response, Compensation, and Liability Information System (CERCLIS) database contains general information on sites across the nation and US territories including location, status, contaminants, and actions taken. It provides information on sites being assessed under the Superfund Program, hazardous waste sites and potential hazardous waste sites.

- KDHE Identified Sites – Contaminated sites managed by the Bureau of Remediation (except for leaking underground or above ground petroleum storage tanks) are included in the Identified Sites List (ISL).

- KDHE AST and UST Assessment Database – this database provides information on site were leaks have occurred or a tank has been closed.

- KDHE Database of Registered USTs

- KDHE Environmental Interest Finder – Kansas consolidated from the Identified Sites List, the AST and UST Assessment Database, and the Database of Registered USTs into an interactive online GIS system. Information in this system was reviewed in February 2023. A link to the KDHE interactive online GIS system is:

  https://maps.kdhe.state.ks.us/keif/

- USEPA Cleanups In My Community (CIMC) Map/Database – EPA and it's state, territory and tribal partners have developed a variety of cleanup programs to assess and, where necessary, clean up these contaminated sites. CIMC is intended to provide information about sites that might need to be cleaned up, are being cleaned up, or have been cleaned, in a particular community or anywhere in the United States. The scope of sites included in the CIMC GIS database are: Brownfields Properties, Brownsfields Grants Jurisdictions, RCRA Corrective Action, Superfund, Federal Facilities and Federal Agency Hazardous Waste Compliance Docket, Removals/Responses, and Recovery Act Funded Cleanups. The link to the CIMC Map/Database is:

  https://ofmpub.epa.gov/apex/cimc/f?p=cimc:MAP:0:::71:P71_WELSEARCH:AL|State|AL|||true|true|true|true|true|true||-1|sites|N|basic

FINDINGS

Below are the findings from the records search:

Superfund Sites

There were no Superfund sites identified in areas of potential soil disturbance.

Sites identified on CERCLIS Database

The CERCLIS Database identified no sites being investigated or remediated for hazardous waste within the areas of potential soil disturbance.

KDHE Identified Sites

There were no identified sites in the proximity of potential soil disturbance.

Solid Waste Facilities

There are no known solid waste facilities in the project area.

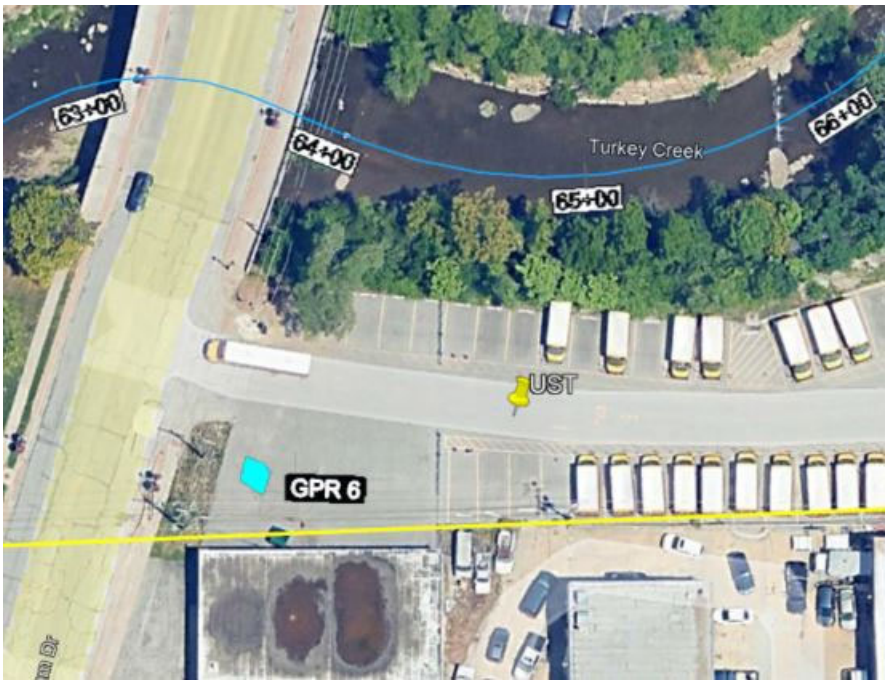
Registered and Closed Underground Storage Tanks (USTs)

There are six properties along the project reach that formerly or currently have USTs. These are described below, working from downstream to upstream.

- 5568 Merriam Dr, Merriam, KS
  State of Kansas records identify this location as either previously or currently having a tank. No other information is provided on the tank size or contents other than it is out of use. The proposed levee is approximately 75-ft from the building on the property and the location of the tank is unknown. There was a Ground Penetrating Radar (GPR) survey performed on the property and two subsurface anomalies were discovered but it is uncertain if these are USTs (see figure below) If the tank on this property did have a past leak, there is the potential petroleum contamination may be encountered when excavating the inspection trench. It is recommend a boring be advanced in the location of the proposed levee to determine contaminated soil will need to be addressed during construction. See Appendix F, Figure F-1 for location.

GPR Anomalies on 5568 Merriam Dr

- 5639 Merriam Drive, Merriam, KS
  This property contained one-300 gallon waste oil UST, a 10,000 gallon gasoline UST, and a 2,000 gallon diesel UST. This USTs and the associated distribution piping were removed. During removal, 20 CY of contaminated soil was removed near the 300 gallon waste oil tank and 150 CY of contaminated soil was removed near the gasoline and diesel tanks. The GPR survey of the property discovered a subsurface anomaly on a property near the entry road to this property (5643 Merriam Dr). However, KDHE records do not identify a UST on 5643 Merriam Dr. This property also has two existing 10,000 gallon USTs that are in use. The presumed location of the existing tank is shown in Appendix F, Figure F-1. They were installed in 2019 and have all the latest protective measures to detect and contain any leakage. The potential of encountering petroleum contamination during construction of the proposed floodwall is believed to be low since contaminated soil was removed during closure of the older tanks. Due to the location of the existing tanks, it does not appear construction of the floodwall will be impacted.



GPR Anomaly on 5643 Merriam Dr

- 5726 Merriam Drive
  During subsurface investigation via borings, debris was discovered on this site. There were no tanks identified in the KDHE records for this property, however a GPR survey identified two subsurface anomalies on the property (see Figure below).

GPR Anomalies on 5726 Merriam Dr

- 5730 Merriam Drive, Merriam KS
  Three 560 gallon gasoline USTs were removed from this property. The KDHE records indicate no contaminated was encountered. (see Appendix F, Figure F-2 for location). The building associated with this property was demolished to develop the Farmers Market.

- 5745 Merriam Dr, Merriam, KS
  Kansas records indicate there was a UST on this property but status except to indicate it is out of use. The location, size, and former contents of the tank are also unknown. The property is more than 300 feet from the proposed levee, so it is unlikely there will be any impact to construction of the levee.

- 5903 Merriam Dr, Merriam, KS
  There are two 10,000 gallon gasoline USTs and one 8,000 gallon diesel UST being actively used on this property (see Appendix F, Figure F-3). This is no indication of past leaks from these tanks and they have spill basins, so it is unlikely contaminated soil will be encountered during installation of the proposed floodwall and gas main.

- 6032 Merriam Dr, Merriam, KS
  There was a 500 gallon waste oil UST removed from this property in 1990. Kansas records indicate the tank did not leak and there was not contaminated soil. Therefore, there is not expected to be any contamination encountered during installation flood wall near this property.

- Additional Subsurface Anomolies
  There were three additional subsurface anomalies discovered at 9400 W 61st St, 9420 W 61st, and 80 feet west of the intersection of Merriam Ln and W 61st st. KDHE records do not identify these properties as having USTs.

GPR Anomalies on 9400, 9420 W 61st St, and 80 feet West of the intersection of W61st and Merriam Ln

Additional information on the GPR survey findings is in the table below.

Ground Penetrating Radar (GPR) Investigation Summary					
GPR #	Approx. Depth (ft)	Approx. Surface Area (sqft)	Approx. Location along UTC Alignment	Bank (Left or Right)	Parcel Location
1	Undetermined	103.6	26+75	R	Northwest corner of Parcel 126
2	4.5	235.8	28+00	R	Southwest edge of Parcel 109
3	3.3	89.1	29+75	R	North edge of Parcel 109 / South edge of Parcel 106
4	Undetermined	319.3	53+30	R	Center West of Parcel 27
5	5.2	77.7	53+50	R	Center East of Parcel 27
6	1.9	13.8	64+00	R	Southeast corner of Parcel 10
7	Undetermined	133.7	62+50	L	Northeast corner of Parcel 17 / Northwest corner of Parcel 15
8	3.3	55.7	63+00	L	Northeast corner of Parcel 15

Spills

There were a number of spills report along the reach of Turkey addressed by this DDR. Most were associated with minor leaks of mineral oil from transformers and contamination associated with the spill was cleaned up. The only significant spill reported is described below:

- 61st and Merriam Ln, Merriam, KS
  On April 11th, 2022, and vehicle accident knocked down three utility poles and impacted four transformers. It was estimated that 91 pints of mineral oil from the leaked from the transformers and 95% of the oil went down a storm drain and into Turkey Creek. The oil did not contain Polychlorinated Biphenyls (PCBs), so it is not anticipated this was negatively impact construction of the proposed levee in this area. See Appendix F, Figure F-5 for location.

Other Areas of Concern

There were two areas of concern identified during investigations performed in February of 2023. A proposed levee crosses the west side of this property and it is also the location of a proposed retention basin. These are described delow:

- 5726 Merriam Dr, Merriam, KS
  In February 2023 railroad ties and debris were encountered while advancing soil boring ADU-212 (see Appendix F, Figure F-2 for location). During advancing of a soil boring in February 2023, railroad ties and debris was encountered. The debris was described as having very poor strength properties as well has having a foul odor. The low strength properties may impact the foundation of the proposed levee and due to the foul odor would not be suitable for the base of the retention basin. All debris removed as part of the levee inspection trench and excavation of the retention basin will need to be disposed of in a permitted landfill. It is recommended additional investigation be performed to determine the nature and extent of the debris to assess the impact to the project.

- 5920 Merriam Dr, Merriam, KS
  In February 2023, petroleum contamination was encountered at a depth of 10 to 11 feet while advancing Boring ADU-201. The source of this contamination is unknown, however a historical aerial photo from 1941 shows a turn in and exit to the site with a small structure. It is speculated this may have been an former gas station but no records could be found. The current use of the property is auto repair. A soil sample was collected and tested for Total Petroleum Hydrocarbon (TPH) and Volatile Organics (VOCs). The results are in Table 1. The only range exceeding the KDHE Tier 2 RSK cleanup level of 250 mg/kg was the Mid Range Hydrocarbons at 316 mg/kg. However, this result is below the Non-Residential Scenario of 350 mg/kg. The VOC analysis was non-detect, which could suggest this is an old spill and the underlying constituents that drive risk associated with TPH have degraded. Since this is a non-residential property, the contaminated soil would likely not need to be cleaned up. However, it would be good practice to segregate contaminated soil during excavation and dispose of it in a permitted landfill. Most petroleum contaminated soil is classified as a Special Waste and typically can be disposed of in a RCRA Subtitle D landfill, which is the same type of landfill that accepts household trash. Additional testing would be necessary to meet disposal facility requirements.

Facilities Handling Hazardous Waste

There are a number of facilities located along the Turkey Creek channel that handle or produce hazardous wastes. These facilities are regulated by USEPA. Although they handle hazardous wastes, there have been no reported spills or areas requiring cleanup that would have an impact on the project.

CONCLUSION/RECOMMENDATIONS

Based upon the findings from the records search performed, there are no known hazardous waste sites that will impact the proposed work. In addition, no solid waste facilities, such as former landfills, were identified at locations that would impact the project. There were several spills reported near Turkey Creek along the reach addressed by this DDR, but they were quickly remediated and should not have any significant impact to the project. There are six properties with current or former USTs, with the current status of the tanks unknown on two of those properties, 5560 Merriam Dr and 5745 Merriam Dr. There is no known existing contamination associated with any of the current or former tank locations, also some contamination was encountered and remediated when the tanks that were closed and removed.

Two areas of concern were discovered during a February 2023 soils investigations. Buried railroad tires and debris were discovered while advancing a boring on 5726 Merriam Dr. This may present foundation issues for the proposed levee along this reach as well as issues with construction of a retention basin proposed on this property. The other issue discovered during February 2023 soil investigations was petroleum contamination on 5920 Merriam Dr at a depth of 10 to 11 feet below the ground surface. Sample results indicated TPH levels above residential values for Mid Range Hydrocarbons but below non-residential levels. VOC analysis results were all non-detect, which suggests the source of contamination is very old and the underlying constituents driving the health-based TPH risk levels have degraded over time.

Overall, the risk of encountering significant environmental/HTRW impacts during construction appear relatively low based on Federal and State environmental records. However, there remains uncertainty about activities that occurred prior to Federal/State regulations being enacted and records kept. An example of this is the debris encountered at 5726 Merriam Dr and the petroleum contamination at 5920 Merriam Dr, both discovered during subsurface investigations performed in February 2023. Neither of these sites were expected to have contamination issues based on environmental records. It is not possible nor cost effective to identify all potential environmental subsurface issues along a greater than one mile stretch of the channel addressed in this DDR. The density of borings and other investigative techniques would be both schedule and cost prohibitive. Therefore, it is recommended that the Contractor be required to develop contingency plans to address unexpected environmental conditions and contingency funding be set aside so unforeseen conditions can be addressed without significant project delays.

As for the two recently discovered sites with environmental concerns, 5726 Merriam Dr. and 5920 Merriam Dr, it is recommended additional investigations be performed to more fully characterize the nature and extent of the

environmental issues on these properties. This will help to determine the engineering measures that should be included in the design and help refine cost impacts to the project. For the debris at 5726 Merriam Dr, it is likely all debris below the proposed features will need to be removed and disposed at a permitted facility. For the petroleum contamination encountered at 5920 Merriam Dr, based on the TPH levels, it does not appear any remedial activities would need to occur. However, it is good practice to segregate any contaminated soil from clean soil excavated and dispose of it at a permitted landfill rather than reusing the soil on site or at other project locations. In this case it would likely be classified as a Special Waste that could be disposed of in a RCRA Subtitle D landfill, which is the type of landfill that accepts typical household waste.

Figure 1-2. Feasibility Recommended Plan 5

SECTION 1
Introduction

1.1 PURPOSE

The purpose of this report is to evaluate the recommended plan from Upper Turkey Creek Johnson County and Wyandotte County, Kansas Flood Risk Management Project Feasibility Report with Integrated Environmental Assessment (2015), also referred to as the Feasibility Study (FS). Changes in criteria and in existing conditions impacting the FS recommended plan will also be evaluated. The findings contained within this report are preliminary and rely heavily on engineering judgment and lessons learned from studies and designs completed on similar projects after the 2015 FS was approved.

1.2 LOCATION

The Upper Turkey Creek Flood Risk Management (FRM) project is a new FRM project located in the City of Merriam, in Johnson County, Kansas. Turkey Creek is a right bank (RB) tributary of the Lower Kansas River located in Johnson and Wyandotte counties, Kansas between approximate river miles (RMs) 2.7 to 3.7. Figure 1-1 shows the location of the Upper Turkey Creek FRM project.

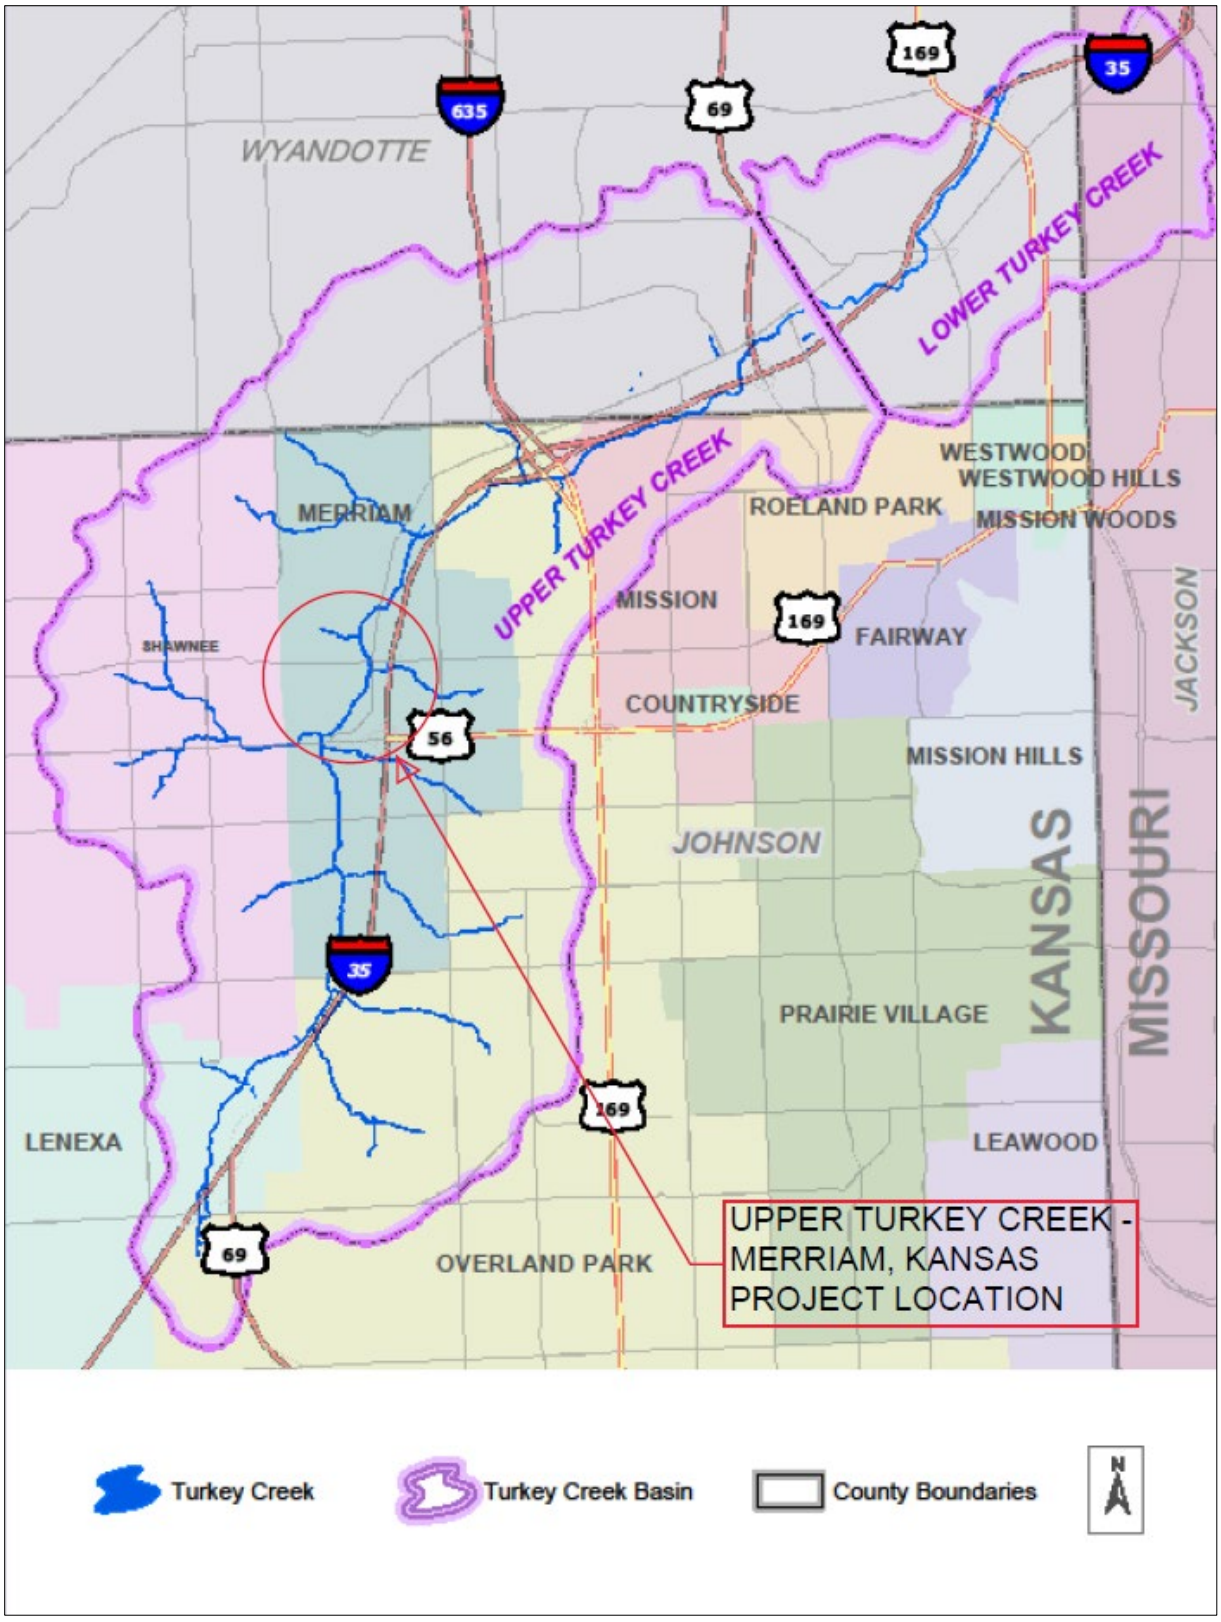

Figure 1-1. Upper Turkey Creek—Merriam, Kansas Location

1.3 PROTECTED AREA DESCRIPTION

The watershed contains some of the most intensely developed urban locations in Johnson and Wyandotte counties, Kansas. Approximately 75 percent of the Turkey Creek watershed consists of residential, commercial, and industrial land use. Most of Turkey Creek and its tributaries have been channelized.

The need for the project lies in the potential for flooding that could result in life loss (LL) and/or property damage in the Upper Turkey Creek Basin. The majority of the Turkey Creek channel that passes through the City of Merriam, Kansas, can contain a 20 percent annual exceedance probability (AEP) (1/5-year event), although two areas flood at the 50 percent AEP (1/2-year event). Flooding in and around Johnson County, Kansas, led to presidential disaster declarations in 1993 and 1998. The estimated cost of these disasters exceeded $50 million. Heavy rains on October 4, 1998, produced flooding that caused several million dollars in damage to businesses and public property along Turkey Creek in Johnson and Wyandotte counties, Kansas. Reports indicate that parts of the Kansas City metropolitan area in both Kansas and Missouri received almost eight inches of rain that day with some locations receiving three to five inches of rain within a three-hour period. More than five inches fell in Lenexa, Kansas, in a little more than an hour. Nearly 100 calls for water rescue were received, and numerous roads throughout the area, including individual sections of Interstate 35 (I-35) and Interstate 435 (I-435), were impassible. Following the 1993 and 1998 flood losses and as Lower Turkey Creek investigations were ongoing, the U.S. House of Representatives Committee on Transportation and Infrastructure passed the 1999 resolution and adopted the Upper Turkey Creek Basin Study authority in 2000.

1.4 FEASIBILITY STUDY

The basis of this project is the recommended plan from the 2015 FS. Most of the protected area is on the RB of Turkey Creek upstream of an authorized FRM project in the downstream 8,700 feet of the Turkey Creek channel, also locally known as Lower Turkey Creek. The Upper Turkey Creek reach includes the main downtown reach of Merriam, Kansas, as well as a commercial and industrial area just south of Johnson Drive. The features, which include earthen levees, floodwalls, and a detention basin, extend upstream to downstream from Shawnee Mission Parkway to Merriam Drive. Figure 1-2 shows the recommended feasibility plan. Unless otherwise specified, consistent with EM 1110-2-6056, “Standards and Procedures for Referencing Project Elevation Grades to Nationwide Vertical Datums”, dated 31 December 2010, all elevations presented in this report are in the North American Vertical Datum of 1988 (NAVD 88).

THIS PAGE IS INTENTIONALLY BLANK.

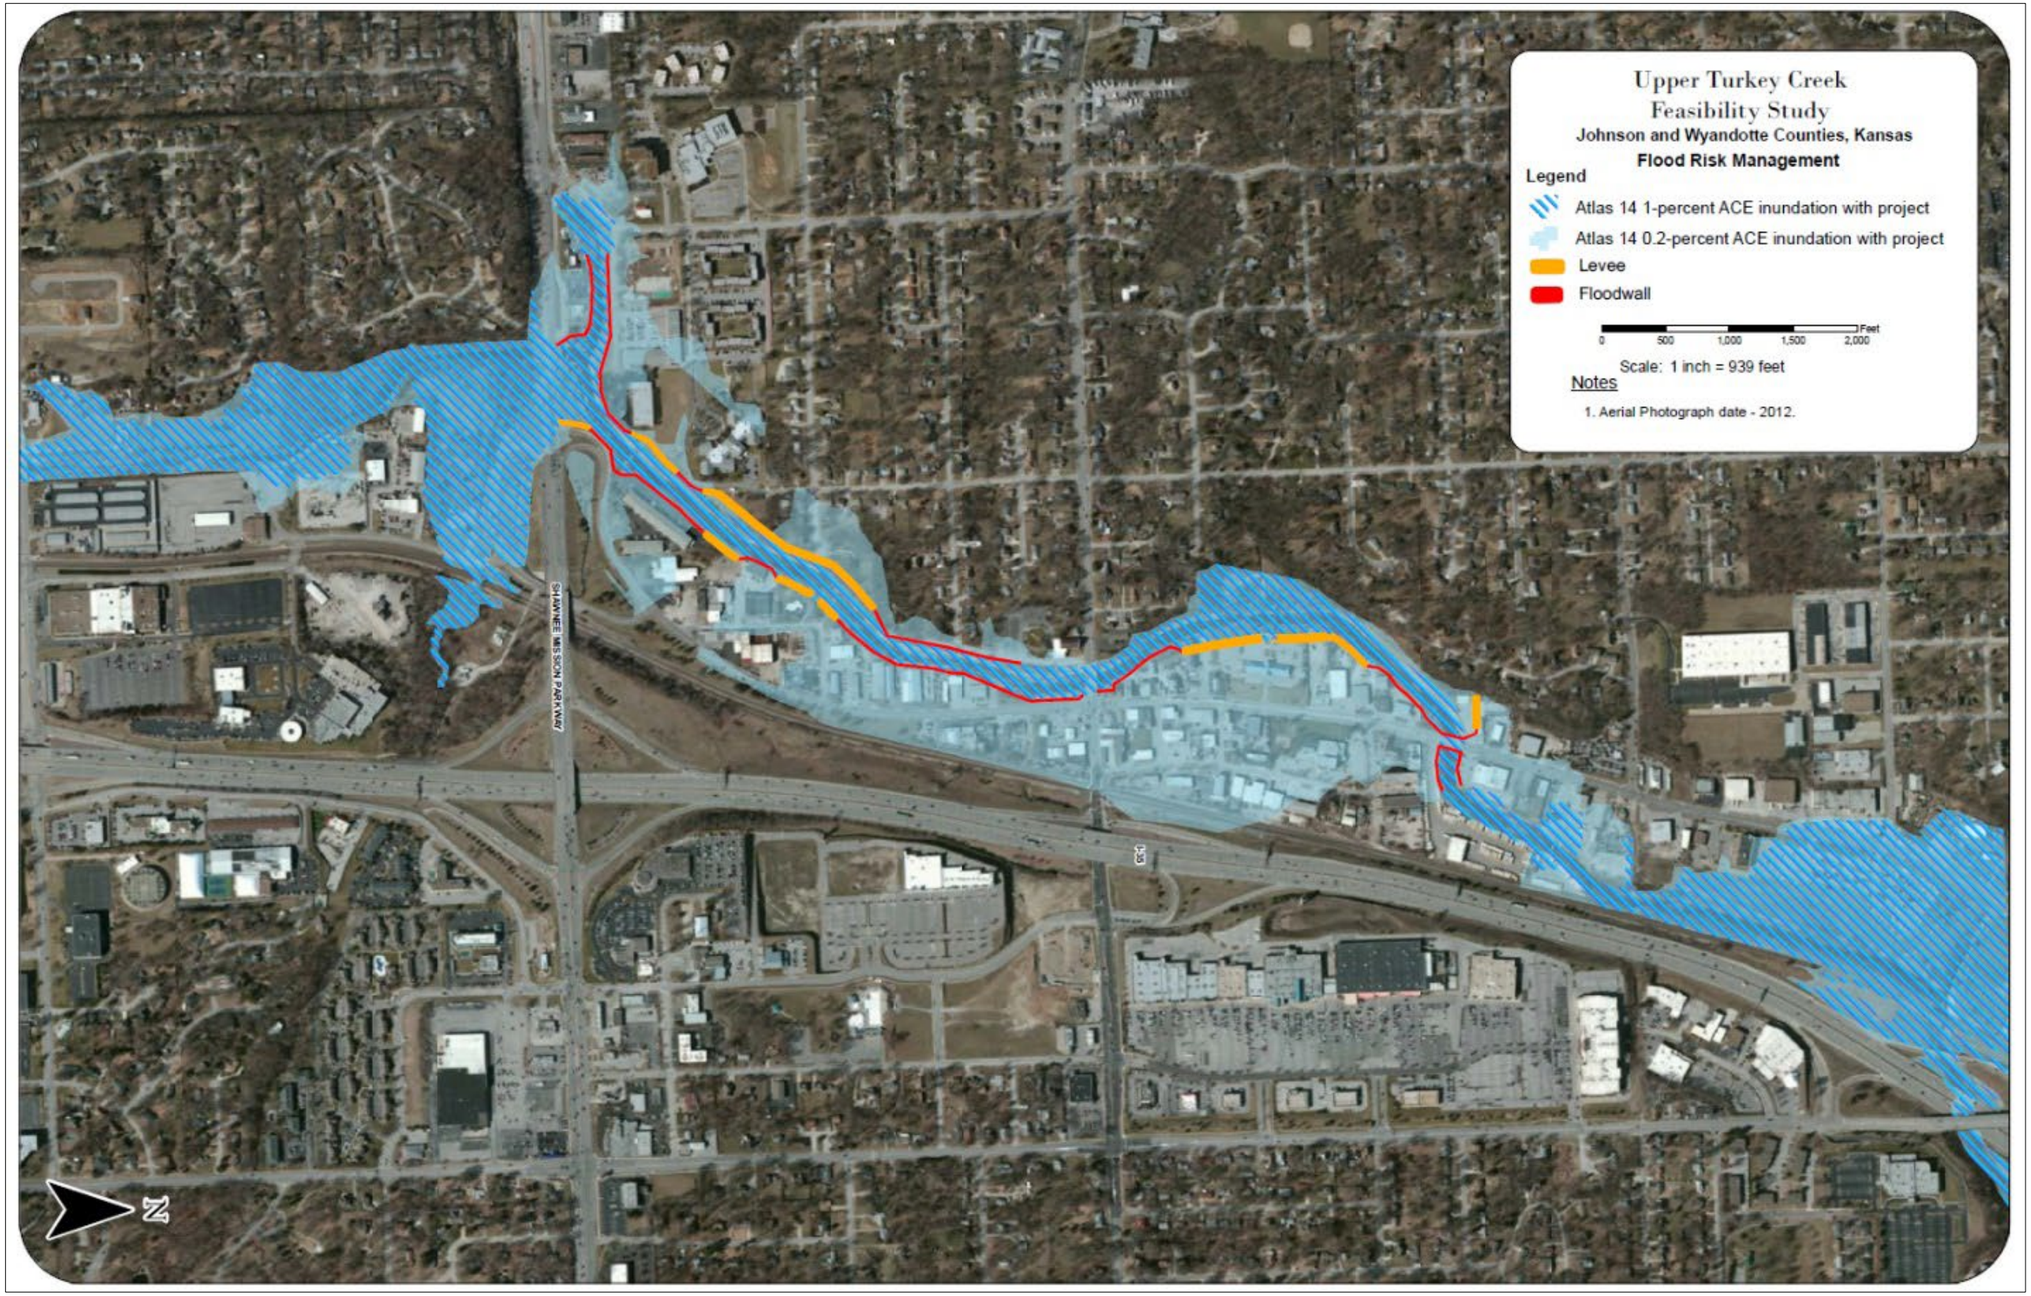

Figure 1-2. Feasibility Recommended Plan

THIS PAGE IS INTENTIONALLY BLANK.

SECTION 2
Feasibility Study Recommended Plan Summary

The 2015 FS recommended plan was formulated and evaluated using updated National Oceanic and Atmospheric Administration (NOAA) Atlas 14 rainfall data. The primary plan features are 3,380 feet of levee up to approximately 6 feet in height and 6,820 feet of floodwall up to approximately 6.5 feet in height. A 2.1-acre-foot, gravity-drained stormwater detention basin is included for interior drainage and is located on the RB adjacent to the Merriam Marketplace near the downstream end of the project. The project also includes stormwater, water and sanitary sewer relocations, and environmental compensatory mitigation of seven acres of mast-producing trees.

2.1 HYDROLOGY AND HYDRAULICS

The hydrologic basis for the FS was based on a HEC-1 model developed by the Larkin Group Inc. (Larkin) for the Johnson County, Kansas, Storm Management Program. The HEC-1 model included the complete watershed contributing to the upper portion of Turkey Creek. Due to the very limited period of record of the Storm Watch System gages in the Turkey Creek watershed at the time of the modeling, and because there is no discharge gaging on Turkey Creek, a gage on Brush Creek was used as an analog for validation of the HEC-1 model of Turkey Creek for the 1998 hydrologic event. It was estimated that the 1998 event exceeded a 1 percent AEP (1/100-year) discharge for Brush Creek, and the hydrologic modeling parameters were adjusted using the observed precipitation within the Brush Creek watershed to calibrate hydraulic modeling with the observed high water marks. Due to the lack of observed precipitation data within the Turkey Creek watershed, a similar correlation of the 1 percent AEP (1/100-year) discharge with the observed high water marks was assumed for Turkey Creek as a validation of adopted hydraulic modeling parameters.

Due to the active development within the Upper Turkey Creek watershed, and the lack of gaging, calibration with previous hydrologic events in 1961, 1977, 1993, and 1998 were not performed. The hydrologic model was completed in 2005 and was generated to support a floodplain mapping initiative in Johnson County, Kansas.

The original Upper Turkey Creek hydrologic analysis was based on NOAA Technical Paper (TP)-40, Rainfall Frequency Atlas of the Eastern United States for Duration from 30 minutes to 24 hours and Return Periods from 1 to 100 Years. An update to the in-progress (at the time) Upper Turkey Creek Feasibility Report was performed in 2014 based on the publishing of the NOAA Atlas 14 point precipitation frequency estimates which were published in 2013. When these updates were made to the modeling, the HEC-1 model was imported into Hydrologic Modeling System (HEC-HMS) version 4.0. Slight edits to the modeling inputs were required to import the model into HEC-HMS, but the extent of these edits was not documented in the feasibility report. Table 4-1 presents the respective TP-40 and Atlas 14 24-hour adopted point precipitation frequencies and annual maximum rainfall totals evaluated during the FS.

The hydraulic modeling for the FS was based upon a River Analysis System (HEC-RAS), version 3.1.3, one-dimensional (1D) steady flow model.

Table 2-1. 24-hour Rainfall Totals per Annual Exceedance Probability

AEP (percentage)	Average Return Period (years)	24-hour Rainfall Amount TP-40/Atlas 14 (inches)
50	2	3.6/3.7
20	5	4.5/4.7
10	10	5.3/5.5
4	25	6.2/6.8
2	50	6.9/7.8
1	100	7.8/8.8
0.5	200	8.4/9.9
0.2	500	9.3/11.4

2.2 LEVEE AND FLOODWALL

The recommended plan consists of construction of levee and floodwall sections along Turkey Creek in the City of Merriam, Kansas, from Shawnee Mission Parkway on the south (upstream end) to Merriam Drive just north of West 57th Street on the north (downstream end). Most of the protected area is on the RB of Turkey Creek. The levee is up to 6 feet in height and includes a homogeneous clay embankment with a 10-foot crest width and 1V:3H side slopes. A floodwall up to 6.5 feet in height will be constructed where there is insufficient space to construct a levee to the design elevation or insufficient space for a minimum slope of 1V:2H from the creek bed to the riverside levee toe.

The floodwall consists of an inverted T-wall design with a base of 10 feet. The FS plan indicates that a key will not be necessary for sliding as the base will be entrenched within the reinforced soil on the landside of the floodwall. Reinforced concrete with a minimum compressive strength of 4,000 pounds per square inch (psi) compressive and stem and footing thicknesses of 18 inches will provide the necessary strength capacity needed to withstand the 1 percent AEP (100-year event) flows with an estimated assurance (conditional non-exceedance probability) of 82.9 percent (floodwall varying 0–6.5 foot tall) level of protection referred to as the Final NED Plan.

The existing Turkey Creek channel in the project area has approximately 1V:1H to 1V:2H side slopes and is lined with stacked limestone blocks. The channel is generally less than 8 feet in depth. The limestone block retaining wall was built in sections from the 1960s to the 1980s and sections of it have been repaired since. The wall is maintained by the Merriam Drainage District (MDD). MDD inspects this area of the creek twice a year. They estimate that ten percent of the original wall has been replaced.

The limestone block retaining wall is a gravity block wall with no reinforcements tying the blocks together. The individual blocks are approximately 6 feet long, 2 feet deep, and 14 to 18 inches tall. The face of each block in the stack is offset approximately 2 inches back from the face of the block below it. There is no drain behind the wall. The wall was backfilled with local soil which appears to be mainly clay. In some recent replacement sections of wall, filter fabric and aggregate backfill were placed behind the wall.

The wall experiences regular breaches with short sections (roughly 100 feet long or less) completely collapsing into the creek (see Section 4.0 of Appendix B-5 of the FS). The cause of the breaches is unknown, but the wall was described in the FS as, “not an engineered structure”. When breaches occur, MDD rebuilds the section with the original limestone blocks. During site visits for the FS, soil was observed migrating through the limestone blocks. The walls were judged to not be capable of providing support to the proposed levee or floodwall.

The recommended plan includes ground improvement in floodwall areas where the projected slope between the proposed floodwall heel and creek bed will be steeper than 1V:2H, totaling approximately two-thirds of the total length of floodwall. No ground improvement is proposed in the leveed areas.

The recommended ground improvement consists of 16-inch diameter, concrete, soil replacement columns extending to the top of bedrock. The columns will be placed approximately 2 feet on-center in an equilateral triangle pattern. The recommended width of ground improvement is 15 feet, centered on the floodwall footing. This ground improvement, consisting of more than 12,000 columns, is intended to provide a floodwall foundation that does not rely on the stability and support of the existing limestone-block retaining wall. The recommended plan is based on the MDD, continuing to repair breached segments of the limestone-block retaining wall so there will not be permanent ongoing scour of the improved ground supporting the floodwall. Discussions will be held with MDD as the design progresses to clarify the sponsor responsibilities and timeframe for repairs.

Table 2-2 details the levee and floodwall quantity breakdown in linear feet. Reach 3b-1 is the Merriam, Kansas downtown area, Reach 3b-2 is the Industrial and Railway Drive (West 61st Street), and Reach 3b-3 is the Parkway Vicinity. Table 2-3 details the extents and locations of the floodwall and levee reaches through the project reach, as well as approximate average heights based on the 2020 light-detection and ranging (LiDAR) surface as compared to the levee profile indicated in the FS final HEC-RAS model. It is noted that the lengths indicated in Table 2-3 are not precisely consistent with those illustrated in GIS files, and that the average heights are based on the reaches delineated in the GIS files.

Table 2-2. Linear Feet of Levee and Floodwall by Reach

Left Bank (LB)	**Reach 3b-1 (feet)**	**Reach 3b-2 (feet)**	**Reach 3b-3 (feet)**
Levee	168	290	1,064
Floodwall	235*	840*	670* and 1,070**
Right Bank (RB)			
Levee	1,051	150	660
Floodwall	1,047* and 300**	1,390**	1,410** and 330*

*Auger Cast Piles (ACP)
**Shallow Footings (SF)

Table 2-3. Breakdown of Approximate Levee and Floodwall Heights by Reach (sheet 1 of 2)

Levees/Floodwalls	Construction Feature(s)
LB	Reach 3b-1—Merriam Downtown • 160 feet of floodwall average height of 5 to 6 feet, downstream of Merriam Drive • 75 feet of floodwall average height of 5 to 6 feet upstream of Merriam Drive • 168 feet of levee average height of 4 feet upstream of Merriam Drive Reach 3b-2—Industrial and Railway Drive (West 61st Street): • 840 feet of floodwall average height of 4 to 6 feet begins at 300 feet upstream of Johnson Drive to 500 feet upstream of West 60th Street • 290 feet of levee average height of 5 feet from 500 feet upstream of West 60th Street to West 61st Street Reach 3b-3—Parkway Vicinity: • 744 feet of levee average height of 3 to 5 feet from West 61st Street to 70 feet downstream of West 62nd Street • 200 feet of floodwall average height of 3 to 5 feet from 70 feet downstream of West 60th Street to 20 feet upstream of West 62nd Street • 320 feet of levee average height of 3 feet from 20 feet upstream of West 62nd Street to 60 feet upstream of the pedestrian bridge (north side of Skate World parking lot) • 1,070 feet of floodwall average height of 3 feet from 60 feet upstream of pedestrian bridge to south side of Skate World parking lot then along west 62nd Terrace

Table 2-4. Breakdown of Approximate Levee and Floodwall Heights by Reach (sheet 2 of 2)

Levees/Floodwalls	Construction Feature(s)
RB	Reach 3b-1—Merriam Downtown: • 220 feet of floodwall average height of 5 to 6 feet downstream of Merriam Drive to Merriam Drive parapet wall • 532 feet of floodwall average height of 5 to 6 feet from Merriam Drive parapet wall to West 57th Street • 1,051 feet of levee average height of 6 feet from West 57th Street to 180 feet south of the farmer's market parking lot • 595 feet of floodwall average height of 6 feet downstream of Johnson Drive Reach 3b-2—Industrial and Railway Drive (West 61st Street): • 1,390 feet of floodwall average height of 4 to 6 feet south of Johnson Drive to 70 feet north of West 61st Street • 150 feet of levee average height of 5 feet to West 61st Street Reach 3b-3—Parkway Vicinity: • 240 feet of levee average height of 3 to 5 feet from West 61st Street to 190 feet north of West 62nd Street • 290 feet of floodwall average height of 5 to 6 feet from 190 feet north of West 62nd Street to West 62nd Street • 240 feet of levee average height of 5 to 6 feet from 62nd Street to 240 feet south of West 62nd Street • 890 feet of floodwall average height of 4 feet from 240 feet south of West 62nd Street to 130 feet north of Shawnee Mission Parkway • 180 feet of levee average height of 5 feet to Shawnee Mission Parkway • 560 feet of floodwall average height of 4 feet on west side of Turkey Creek extending to north of Shawnee Mission Parkway and running along south side of drainage ditch that runs parallel to West 62nd Terrace

2.3 BRIDGE MODIFICATIONS

The recommended plan constructing a 4- to 6-foot, reinforced concrete headwall on the upstream and downstream sides of the Merriam Drive Bridge (Reach 3b-1), respectively, to maintain flows in the creek channel and reduce overtopping of the bridge during higher intensity storm events. The Shawnee Mission Parkway bridge was assumed to overtop to minimize induced damages upstream as stated in the FS.

The pedestrian bridge located at RM Station 3.57 (Reach 3b-3) requires an extension to span 175 feet across the new levee and floodwall system. It is expected the extension will consist of additional span(s) to the bridge and a possible raise of the abutments.

2.4 UTILITIES

The FS investigated known utilities within the recommended plan's project limits. All the storm, sanitary, domestic water, electrical, and natural gas facilities identified in the FS that cross a proposed levee or floodwall have recommended relocations and/or modifications for the project. Table 2-5 summarizes the general recommendations according to the utility. Information specific to each utility type is detailed in the following subsections.

Table 2-5. Utility Relocation Summary

Utility	Existing Facility Type	General Recommended Relocation Crossing Levee Embankment or Floodwall
Sanitary Sewer	12-inch polyvinyl chloride (PVC) (assumed)	• Remove existing sanitary pipe and replace with 12-inch reinforced concrete pipe (RCP). • Install manholes on landside.
Storm	Varies	• Install manhole on landside. • Install gate box on riverside with flap gate. • If installation of riverside gate box is not feasible, install flap gate at floodwall or flap gate at headwall. • Remove existing storm pipe and replace with minimum 24-inch RCP under levee/floodwall.* • Grout-fill pipes to abandon if removal is not feasible.
Water	6-inch and 8-inch ductile iron pipe (DIP) (assumed)**	• Remove and replace with DIP. • Encase any waterline passing through the channel with concrete encasement.
Electric	Overhead electric	Relocate vertically to provide adequate clearance.
Natural Gas	PE (assumed)	Remove polyethylene (PE) pipes and replace with PE pipes.***

*FS indicated the Civil Design and Geotechnical Sections determined a minimum of 24-inch RCP is acceptable. This is a deviation from the minimum 48-inch RCP prescribed in Kansas City District guidance under urban levees. The use of 24-inch RCP requires inspection of these structures with video equipment in place of manual inspection.
**FS indicated limited information is known about the construction material used in existing water lines within the flood corridor. Additional investigations will be performed during the design phase to obtain more information on the existing water lines.
***FS indicated Turkey Creek high water events have durations of a few hours. During feasibility, geotechnical engineering judgement determined underseepage landward of floodwalls/levees is not a concern. If underseepage is not a concern, PE pipe does not risk flotation.

2.4.1 Storm

The recommended plan within the FS identified 44 existing stormwater lines within the project area. A total of 27 locations where existing stormwater lines would cross under the proposed levee or floodwall were identified. See Appendix C for a summary of storm drainage structure existing versus proposed conditions. See Table 2-6 for a general summary of stormwater structure modifications per FS recommended plan.

The FS identified that the addition of proposed levees and floodwalls would require interior drainage management. Interior drainage alternatives including pump stations, underground detention (a concrete box with a series of inlets at ground level placed parallel to the levee), and surface detention were discussed in the FS. A surface detention basin was recommended in the FS recommended plan. Section 2.5 contains additional information on the surfaced detention, herein referred to as the detention basin.

Numerous private storm water lines are assumed to exist within the project area based on site observations of small diameter pipes daylighting into Turkey Creek. Private storm water lines were not

identified within the FS. Private storm water lines will be investigated and evaluated during the next design phase.

Table 2-6. Stormwater Structure Modifications per Feasibility Study Recommended Plan

Location	Stormwater Structure Modification
Landside	Install manhole on landside.
Riverside	Install gate box on riverside with flap gate. If installation of riverside gate box is not feasible, install flap gate at floodwall or flap gate at headwall.
Riverside	Install headwall and flap gates at the existing triple 7-foot by 7-foot reinforced concrete box (RCB) drainage structure at Station 3.109
Under proposed levee/floodwall	Remove existing storm pipe and replace with a minimum 24-inch RCP under levee/floodwall. Abandon grout fill pipes if removal is not feasible.

2.4.2 Sanitary

The recommended plan within the FS identified seven locations where sanitary relocations may be required. Approximately 4,190 feet of 12-inch PVC and 36 total 48-inch diameter manholes were proposed in the FS. Table 2-7 shows a summary of the proposed sanitary sewer relocations.

Table 2-7. Proposed Sanitary Relocation per Feasibility Study

Existing Facility Type	Approximate Station Location (Per FS Stationing)	Proposed Relocation Description	Proposed Approximate Relocation Length (feet)	Number of Proposed 48-inch Diameter Manholes
12-inch PVC	Station 3.664	Under LB floodwall, creek, and RB floodwall	330	3
12-inch PVC	Station 3.480	Under LB levee upstream to Station 3.630	970	8
12-inch PVC	Station 3.400	Under LB levee	130	2
12-inch PVC	Station 3.104	LB relocation upstream to Station 3.282	770	6
12-inch PVC	Station 3.045	Under RB floodwall and creek	220	3
12-inch PVC	Station 2.730	Under 3 creek crossings and RB relocations upstream to Station 3.010	1,670	12
12-inch PVC	Station 2.640	Under LB floodwall	100	2

2.4.3 Domestic Water

The recommended plan within the FS identified four locations where domestic water relocations may be required. The recommended plan assumes domestic water lines will be replaced with DIP based on discussions with the civil engineer and lead planner. Table 2-8 shows a summary of the proposed domestic water.

Table 2-8. Proposed Domestic Water Relocations per Feasibility Study

Existing Facility Type	Approximate Station Location (Per FS Stationing)	Proposed Relocation Description	Proposed Approximate Relocation Length (feet)
6-inch and 8-inch DIP	Station 3.610	Up and over floodwalls and levee	890
8-inch DIP	Station 3.100	Up and over floodwall. Use 8-inch restrained joint DIP. Concrete encased 8-inch DIP for waterline passing through the channel.	280
1-inch steel	Station 3.040	Excavate and replace with one-inch welded steel pipe	50
8-inch DIP	Station 2.623	Up and over the floodwalls with 8-inch restrained joint DIP. Line parallel to and behind the east Merriam Drive curb.	190

2.4.4 Electrical

The recommended plan within the FS identified one location where electrical line relocation may be required. Table 2-9 shows a summary of the proposed electrical relocation.

Table 2-9. Proposed Electrical Relocation per Feasibility Study

Existing Facility Type	Approximate Station Location (Per FS Stationing)	Proposed Relocation Description	Proposed Approximate Relocation Length (feet)
Electrical line	Station 3.350	Up and over LB and RB levees to provide adequate vertical clearance between power line and top of levees. Relocate horizontally on LB to accommodate levee alignment	425

2.4.5 Natural Gas

The recommended plan identified three locations where gas modifications may be required. Table 2-10 shows a summary of the proposed natural gas relocations.

Table 2-10. Proposed Natural Gas Relocations per Feasibility Study

Existing Facility Type	Approximate Station Location (Per FS Stationing)	Proposed Relocation Description	Proposed Approximate Relocation Length (feet)
2 2-inch PE pipes (PE assumed)	Station 3.190	If geotechnical engineering determines underseepage landward of floodwalls/levees is not a concern, then PE pipe does not risk flotation.	TBD
8-inch (material unknown)	Station 2.070*	Up and over the floodwall.	270
4-inch steel	Station 2.623	Up and over floodwall	50

*Station 2.070 gas relocate may be incorrect location in FS as proposed project limits are from approximate Station 3+73 to 2+60.

2.5 DETENTION

A 2.14 acre-foot grassed detention basin, with dimensions of 80 feet wide by 280 feet in length with 3H:1V side slopes and a 60-inch RCP outfall with flap gate, was proposed in the recommended plan to collect stormwater runoff originating from locations landward of the levees and floodwall. The location of this structure is proposed to be north of the current Merriam Marketplace. The detention basin was designed for the 10 percent AEP (1/10-year) event which was determined to be 5.4 inches of excess precipitation by a 2002 study completed by the University of Kansas and American Public Works Association (APWA) of Kansas City. This value is consistent with the current Atlas 14 precipitation depth for the 10 percent AEP (1/10-year) event. No additional detention features were indicated in the feasibility report.

Based on this assumed feasibility-level design, it is anticipated that the design of the constructed feature will incorporate the current U.S. Army Corps of Engineers (USACE) design criteria and guidance and/or local design criteria and guidance.

It is assumed that the facility will be a dry detention facility holding no permanent pool within the detention basin. Baseflows and flows from the contributing watersheds and/or interior drainage may empty through the detention basin to Turkey Creek. It is assumed that no additional sedimentation volume will be incorporated into the detention basin volume due to it not storing a constant pool elevation and it is anticipated that any accumulated sediment and/or debris could be removed in the periods between runoff events. Debris and/or sediment removal schedules and potential costs will need to be documented in the Operations and Maintenance (O&M) manual generated for the project.

USACE design criteria for the detention basin is anticipated to incorporate guidance from Engineering Manual (EM) 1110-2-1413, Hydrologic Analysis of Interior Areas, and include an evaluation of coincident events, including temporary detention of interior drainage during a Turkey Creek mainstem flood event, as well as the design of facilities capable of passing interior drainage during a relatively frequent and low magnitude Turkey Creek mainstem flow event. Due to the relatively small size of the Turkey Creek contributing watershed, it is anticipated the most likely scenario will involve a simultaneous precipitation

event over the interior area while an infrequent and high magnitude flow is occurring on the Turkey Creek mainstem. Based on EM 1110-2-1413 design criteria, generally speaking, "…The minimum [interior drainage] facility should provide interior flood relief such that during low exterior stages (gravity conditions) the local storm drainage system functions essentially as it did without a levee in place for floods up to that of the storm sewer design…"

According to City of Merriam, Kansas, ordinances, Chapter 26—Environment; Article III, Stormwater Management; Division 1, Section 26-170, APWA Standard Specifications and Design Criteria, Section 5600, Storm Drainage Systems (Kansas City Metropolitan Chapter, 2011) and the Urban Drainage Design Manual Hydraulic Engineering Circular No. 22 (HEC-22-FHWA-SA-96-078, U.S. Department of Transportation, Federal Highway Administration, 1996) should be used as the criteria for the design of stormwater management systems. In accordance with APWA 5600 and HEC-22, the design frequency coincidence is presented in Table 7-3 of HEC-22. This table indicates that for a 1 percent AEP (1/100-year) Turkey Creek design event that the coincident tributary design will correspond with a 4 percent AEP (1/25-year) event. Conversely, a 4 percent AEP (1/25-year) event on Turkey Creek should be evaluated with a 1 percent AEP (1/100-year) for the tributary. These values are based upon the contributing area of approximately 350:1 for the ratio of the Upper Turkey Creek watershed to the interior drainage area for the proposed project, and conservatively correlating the 350:1 ratio to the 100:1 ratio presented in Table 7-3 of HEC-22.

APWA 5600, Section 5608, Stormwater Detention and Retention provides guidance on the evaluation and design of detention basins and indicates the design consideration for the primary outlet works and emergency spillway. Pertinent design criteria and/or guidance are:

- Excerpted from APWA 5600, Section 5608.4, "Performance Criteria":

  E. "…**Primary Outlet Works:** The primary outlet shall be designed to meet the following requirements:

  1. The outlet shall be designed to function without requiring attendance or operation of any kind requiring use of equipment or tools, or any mechanical devices.
  2. All discharge from the detention facility when inflow is equal to or less than the maximum design storm under the required Strategy shall be via the Primary outlet system.
  3. The design discharge rate via the outlet shall continuously increase with increasing head and shall have hydraulic characteristics similar to weirs, orifices or pipes.
  4. For dry detention basins not providing extended detention, the design shall allow for discharge of at least 80 percent of the detention storage volume within 24 hours after the peak or center of mass of the inflow has entered the detention basin.
  5. Ponds shall be designed with a non-clogging outlet such as a reverse-slope pipe, or a weir outlet with a trash rack. A reverse-slope pipe draws from below the permanent pool extending in a reverse angle up to the riser and establishes the water elevation of the permanent pool. Because these outlets draw water from below the level of the permanent pool, they are less likely to be clogged by floating debris.
  6. All openings shall be protected by trash racks, grates, stone filters, or other approved devices to ensure that the outlet works will remain functional. Minimum orifice size shall be per the current version MARC/APWA BMP Manual. See MARC/APWA BMP Manual Sections 8.6, 8.10 and 8.12 for design guidance and typical details for low-flow outlets and trash rack designs. Note that multiple design options are available for non-clogging low flow outlets and debris collection and designers are encouraged to select the best design for their site.

  F. **Emergency Spillways:** The emergency spillway may either be combined with the outlet works or be a separate structure or channel meeting the following criteria.

1. **Elevation:** Emergency spillways shall be designed so that their crest elevation is 0.5 feet or more above the maximum water surface elevation in the detention facility attained by the maximum design storm under the required Strategy for the facility.

2. **Capacity:** In cases where the impoundment/emergency spillway is not regulated by either State or Federal agencies, the emergency spillway shall be designed to pass the 1% storm with 1 foot of freeboard from the design stage to the top of dam, assuming zero available storage in the basin and zero flow through the primary outlet. This design provides an added level of protection in the event of a clogged primary outlet or a subsequent 1% storm event that occurs before the flood pool from the initial storm event recedes to the principal outlet elevation.

G. Drawdown Provision: Drain works consisting of valves, gates, pipes, and other devices as necessary to completely drain the facility in 72 hours or less when required for maintenance or inspection shall be provided.

H. Erosion Control: Primary outlet works, emergency spillways, and drain works, as well as conveyance system entrances to detention basins shall be equipped with energy dissipating devices as necessary to limit shear stresses on receiving channels…"

- Excerpted from APWA 5600, Section 5608.5, "Detention Methods":

B. "…**Dry Detention Facility:** For basins designed to be normally dry:

1. **Interior Drainage for non-BMP basins:** Provisions must be incorporated to facilitate interior drainage to outlet structures. Grades for drainage facilities shall not be less than two percent on turf.
2. **Earth Bottoms:** Earth bottoms shall be vegetated.
3. **Side Slopes:** The side slopes of dry ponds should be relatively flat to reduce safety risks and help to lengthen the effective flow path. Slopes shall not be steeper than three horizontal to one vertical and at least 25% of the perimeter shall have a slope of 5 to 1 or flatter.
4. Refer to the MARC/APWA BMP Manual for design requirements on facilities providing control of the WQv (Comprehensive and Frequent Event Strategies)…"

- Excerpted from APWA 5600, Section 5608.7, "Additional Requirements":

A. "…**Access:** Provisions shall be made to permit access and use of auxiliary equipment to facilitate emptying, cleaning, maintenance, or for emergency purposes…"

SECTION 3
Feasibility Study Recommended Plan Modifications

The information within Section 3 is a summary of changes to the FS recommended plan. Section 4 contains details of the analyses performed on the recommended plan.

3.1 BRIDGES

There are three bridges within the project limits that may require relocation or modification based on preliminary findings. A value-engineering (VE) analysis was suggested by the project delivery team (PDT) to occur between the preliminary FS validation and 35 percent design completion. The purpose of the VE study would be to review the existing bridges and determine to what extent the bridges need modification or relocation.

3.1.1 Merriam Drive Bridge (Reach 3b-1)

Preliminary analysis during feasibility did not adequately address uplift and overturning of bridge and hydraulic surcharge forces on the 6.5 feet headwall caused by the 0.5 percent AEP event (1/200-year). The PDT should analyze a parapet wall height that will be adequate for the uplift and overturning on the current bridge and a cost estimate completed. In addition, a cost estimate for a new bridge with more freeboard and channel improvements to allow greater flows to pass should be investigated. The two cost estimates should be compared, and a cost to benefit ratio completed to determine the best path forward.

3.1.2 Farmer's Market Pedestrian Bridge RM 2.875 (Crossing #5 As-Built Drawings Station 85+10.22)

At this point in time, the H&H model is still in progress and a determination has yet to be made on which AEP will control for flows in the channel and how the pedestrian bridges impact that flow. Therefore, modifications to the FS recommended plan will need to be evaluated during design.

3.1.3 Pedestrian Bridge at RM 3.57 (Crossing #2 As-Built Drawings Station 49+72)

The pedestrian bridge at this location may need to be lengthened beyond the existing span by adding new spans in order to tie into a new levee on the west side and new floodwalls on the east side. The length of the new spans cannot be determined until the location of the new levee and new floodwall alignments are established. Survey data will be reviewed and compared to the AEP to determine if the bridge needs to be raised to clear the water surface elevation (WSE).

3.2 DETENTION

No changes to the proposed detention facilities are proposed at this time, however, an updated evaluation of the design presented in the FS will be undertaken as part of the updated design. A validation of the feasibility hydraulic modeling results and an update to the hydraulic analysis is being undertaken using more modern modeling capabilities.

3.3 HYDROLOGY AND HYDRAULICS

Section 3.3.1 contains a summary of hydrologic and hydraulic changes from the FS recommended plan.

3.3.1 Hydrology

Changes to the hydrology could occur during the project development phase due to an ongoing analysis with Federal Emergency Management Agency (FEMA) and its local and regional partners to update existing floodplain mapping. The analyses are ongoing as of March 2023, and preliminary and/or reviewed results were not available at the time of the development of this report. Preliminary hydrology results are anticipated to be available in the June to July 2023 timeframe based on the current schedule; however, the FEMA review and adoption process will not be complete at that time. Updated modeling software, validation efforts, increased levels of detail, and variations in parameterization may result in differing values from the hydrology adopted for the FS and this analysis. Updated modeling information will be incorporated into the design as it becomes available, pending appropriate reviews. The existing modeling adopted for this analysis remains applicable to the project site and watershed and represents the most current data source until the updated modeling has been properly reviewed and made available for consideration within this design effort. It is anticipated that the hydrology for the mainstem of Turkey Creek will be validated or updated according to the ongoing FEMA analysis for the current design effort, and that the interior drainage will be analyzed and that interior drainage features will be incorporated into the final project design.

3.3.2 Hydraulics

Due to the age of the recommended alternative from the FS, and changes observed within the watershed, it is anticipated the existing condition's hydraulic profile may have changed, and an update to the design profile should be performed. Coordination between the USACE and project sponsors will be required to select the adopted design profile based on the validation effort and current hydraulic analysis. Channel armoring and maintenance efforts have been an ongoing process with the MDD since the FS was completed.

Unsteady two-dimensional (2D) hydraulic modeling is being used to update the design profile in consideration of the increased level of detail and hydraulic modeling capabilities, as well as changes to the stream channel that have occurred since the completion of the FS. Unsteady flow hydrographs computed during the FS are being adapted and used for the current modeling effort to compare the steady flow profiles from the FS with the unsteady flow profiles generated during this modeling update and validation effort. Appendix E presents further detail regarding the modeling validation and development.

3.4 STORM DRAINAGE STRUCTURES

EM 1110-2-2902, Conduits Pipes and Culverts Associated with Dams and Levee Systems was updated in December 2020, after the completion of the FS. Closure type requirements based on pipe diameter and flood rise are now prescribed in the updated EM 1110-2-2902. The closure type requirements are for new construction but are also highly recommended for retrofitting existing pipes. Table 3-1 summarizes the active closure requirements.

Table 3-1. Closure Type Requirements[1]

Flood Rise[2]	Pipe Diameter (inches)	Closure Configuration
Fast	<36	(1)Passive
Fast	≥36	(1)Passive AND (1)Active
Slow	<36	(1)Passive OR (1)Active
Slow	≥36	(1)Passive AND (1)Active OR (2)Active

[1]Table 9-1 of EM 1110-2-2902

[2]Fast flood rise refers to floods capable of rising to a flood stage with less than 12 hours prediction time.

The PDT recommends a deviation from Table 9-1 in EM 1110-2-2902 to use two passive closures for pipes greater than or equal to 36 inches. This recommendation is based on concerns that it is not feasible for the sponsor to manually operate over 10 sluices gates throughout the project with less than 12 hours prediction time.

The PDT will further evaluate the feasibility and applicability of two passive closure structures on pipes greater than or equal to 36 inches as we progress through design. If a deviation from the requirements within EM 1110-2-2902 is required, the PDT will provide justifications for deviations and waivers from mandatory design standards in a memorandum. The memorandum will include a risk assessment and rationales for the deviation.

Table 3-2 summarizes modifications to the FS recommended plan. Table 3-3 summarizes approximate storm drainage quantities.

Table 3-2. Storm Drainage Modifications to Feasibility Study Recommended Plan

FS Recommended Plan	Modification to FS Recommended Plan	Current Recommended Plan
Install manhole on landside	Yes	For pipes <36 inches: • Install landside manhole (no landside flap gate). For pipes ≥36 inches: • Install landside flap gate within gate box.
Remove existing storm pipe and replace with a minimum 24-inch RCP under levee/floodwall. Abandon grout fill pipes if removal is not feasible.	No	Remove existing storm pipe and replace with a minimum 24-inch RCP under levee/floodwall. Abandon grout fill pipes if removal is not feasible.
Install gate box on riverside with flap gate. If installation of riverside gate box is not feasible, install flap gate at floodwall or flap gate at headwall.	No	Install gate box on riverside with flap gate. If installation of riverside gate box is not feasible, install flap gate at floodwall or flap gate at headwall.
Install headwall and flap gates at the existing triple 7-foot by 7-foot RCB drainage structure at Station 3.109	Yes	Install headwall and flap gates at the existing riverside triple 7-foot by 7-foot RCB drainage structure at Station 3.109. Install landside flap gates within landside gate box.

Table 3-3. Approximate Storm Drainage Quantities (Sheet 1 of 3)

	FS Recommended Plan	Modifications to FS Recommended Plan	Notes for Modifications to FS Recommended Plan
Pipes <36 inches Number of Riverside Flap Gates Anticipated	14	14	• 14 total riverside 24-inch flap gates
Pipes ≥36 inches Number of Riverside Flap Gates Anticipated	11	11	• 4 total riverside 36-inch flap gates • 1 total riverside 42-inch flap gate • 1 total riverside 48-inch flap gate • 1 total riverside 54-inch flap gate • 1 total riverside 60-inch flap gate • 3 total riverside 7-foot by 7-foot flap gates
Pipes ≥36 inches Number of Landside Flap Gates Anticipated	0	11	• 4 total 36-inch landside flap gates • 1 total 42-inch landside flap gate • 1 total 48-inch landside flap gate • 1 total 54-inch landside flap gate • 1 total 60-inch landside flap gates • 3 total 7-foot by 7-foot landside flap gates

Table 3-3. Approximate Storm Drainage Quantities (Sheet 2 of 3)

	FS Recommended Plan	Modifications to FS Recommended Plan	Notes for Modifications to FS Recommended Plan
Number of Riverside Gate Boxes Anticipated	19	19	• 11 total gate boxes for 24-inch flap gate • 5 total gate boxes for 36-inch flap gate • 1 total gate box for 42-inch flap gate • 1 total gate box for 48-inch flap gate • 1 total gate box for 60-inch flap gate
Number of Landside Gate Boxes Anticipated	0	9	• 4 total landside gate boxes for 36-inch flap gates • 1 total landside gate box for 42-inch flap gate • 1 total landside gate box for 48-inch flap gate • 1 total landside gate box for 54-inch flap gate • 1 total landside gate box for 60-inch flap gate • 1 total landside gate box for 7-foot by 7-foot landside flap gate
Number of Landside Manholes Anticipated	33	27	Manholes anticipated include: • 21 total 48-inch manholes (including 13 associated with re-routing) • 6 total 60-inch manholes
Approximate Linear Feet of Storm Pipe Removed Under Levee Unit	1,460	1,460	Storm pipe removal anticipated under levee unit includes: • 385 linear feet of 12-inch pipe • 50 linear feet of 18-inch pipe • 385 linear feet of 24-inch pipe • 150 linear feet of 36-inch pipe • 50 linear feet of 42-inch pipe • 30 linear feet of 54-inch pipe

Table 3-3. Approximate Storm Drainage Quantities (Sheet 3 of 3)

	FS Recommended Plan	Modifications to FS Recommended Plan	Notes for Modifications to FS Recommended Plan
Approximate Linear Feet of Storm Pipe Replaced Under Levee Unit	890	965	Storm pipe replacement anticipated under levee unit includes: • 610 linear feet of 24-inch RCP • 150 linear feet of 36-inch RCP • 100 linear feet of 48-inch RCP • 30 linear feet of 54-inch RCP
Approximate Linear Feet of Storm Pipe Removed for Pipe Rerouting (Not Under Levee Unit)**	510	510	Storm pipe removal anticipated for pipe rerouting includes: • 75 linear feet of 8-inch pipe • 220 linear feet of 12-inch pipe • 70 linear feet of 18-inch pipe • 50 linear feet of 24-inch pipe • 95 linear feet of 36-inch pipe
Approximate Linear Feet of Storm Pipe Replaced for Pipe Rerouting (Not Under Levee Unit)**	1,025	1,025	Storm pipe replacement anticipated for pipe rerouting includes: • 325 linear feet of 12-inch pipe • 200 linear feet of 18-inch pipe • 400 linear feet of 24-inch pipe • 100 linear feet of 36-inch pipe

**Rerouting of storm pipe includes reroutes for the proposed detention basin. Anticipate 350 linear feet of storm pipe removal, 625 linear feet of storm pipe replacement, and 1 total 60-inch manholes, and 12 total 48-inch manholes. The proposed detention basin outlet structure will consist of a gate box and a 60-inch flap gate.

SECTION 4
Feasibility Study Recommended Plan Preliminary Analysis

The preliminary analysis contained herein is meant as a review of FS recommended plan. The analysis relies heavily on engineering judgment. As the project progresses to the 35 percent design submittal, engineering judgment will be replaced with detailed engineering analysis.

4.1 HYDROLOGY AND HYDRAULICS

The hydrologic modeling from the FS is currently being carried forward unchanged for this analysis pending the completion of the FEMA analysis currently underway. Following the completion of the FEMA analysis and a review by USACE personnel, it is anticipated that a verification of the results will be undertaken for the project site, and that some modifications to the developed modeling for the design of the authorized project will occur to adapt the FEMA-generated hydrology to this analysis and for this project.

Johnson County, Kansas, initiated a hydrologic modeling effort for Turkey and Brush Creeks in calendar year 2023. This effort will incorporate updated hydrology into the current design effort at the conclusion of the analysis. This effort will include 2D rain-on-grid analysis and spatially-varied Atlas 14 precipitation frequency analyses, as well as validation and/or calibration efforts corresponding with observed precipitation events.

The hydraulic modeling for the existing conditions and FS validation effort is based upon a HEC-RAS, version 6.3.1, 2D unsteady model. If software updates occur prior to the completion of the modeling efforts, the most current version of the HEC-RAS software will be used. The top of levee profile indicated in the FS was not consistent between Table 3-7 of the report, and the final HEC-RAS modeling. Table 4-1 presents both datasets. Based upon an examination of project records, the table to the right in Table 4-1, “Final FS HEC-RAS Model” was the value adopted for the FS engineered design.

Due to uncertainties relating to the development of the Turkey Creek watershed over the previous 30 or more years, a lack of records of channel modifications, and the lack of flow data to calibrate with observed stage data, a calibration of the recently developed 2D hydraulic model using historic data was not performed as part of the current hydraulic analysis. Roughness parameters generally consistent with the FS modeling have been adopted, and bridge and culvert structures are simulated according to the structures’ current configuration as of April 2023.

The FS levee and floodwall design profile was originally based upon the 0.5 percent AEP TP-40 flow profile and was designed to pass flows corresponding with the TP-40 1 percent AEP-computed discharges from the hydrologic modeling. During the development of the report, NOAA Atlas 14 was published, and a revision to the hydrologic analysis was performed to evaluate the levee and floodwall profile design in consideration of the NOAA Atlas 14 1 percent AEP precipitation depths. In consultation with the project sponsor, and following an update to the economic analysis, revisions to the design levee and floodwall profile were implemented to allow for the Recommended Alternative 2d levee and floodwall profile to be able to pass the Atlas 14 1 percent AEP flows. This revised levee and floodwall design profile did not provide sufficient height to meet the desired 90 percent assurance (conditional non-exceedance probability) and provided an estimated 82.9 percent assurance for the Atlas 14 1 percent AEP discharges.

4.2 CLIMATE CHANGE ANALYSIS

A climate change analysis consistent with Engineering and Construction Bulletin (ECB) 2014-10 was developed as part of the FS. A qualitative consideration of the impacts to the hydrology due to potential climate change is presented in the FS. Since the FS was completed, ECB 2014-10, Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects, has been updated to ECB 2018-14, Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects, and two revisions have been published. The current edition, with an expiration date of 19 August 2024, was published on 19 August 2022.

The ECB does not anticipate that the climate change analysis would alter the numerical analysis for the other non-climate aspects of the required hydrologic analyses. The qualitative analysis can inform the decision process related to project planning, engineering, and O&M. Examples of how the qualitative analysis may influence the project design include considering whether the project could be modified in the future or if another strategy should be considered to accommodate projected future increases in discharge. A climate change analysis will be performed as part of the design process and according to ECB 2018-14 or the most current version of USACE guidance if the above document is superseded.

4.3 UNDERSEEPAGE

Underseepage analysis was not documented in the FS. Preliminary underseepage analysis was performed as part of this report (see Appendix B.1). The two existing soil borings near the current project, DC-4, and DC-5, did not show a pervious blanket (foundation sand) in the soil profile. Both borings showed a continuous impervious blanket of clay and weathered shale overlying limestone bedrock approximately 13 feet below existing grade. In other areas, a zone of foundation sand may exist between the impervious clay blanket and bedrock. Even if the impervious blanket is continuous to bedrock throughout the levee unit, vertical underseepage pressures may build up through joints and seams in the bedrock. This may be modeled as a zone of foundation sand.

The preliminary analysis checked sensitivity of the vertical underseepage gradient factor of safety for top of levee (TOL) loading to increasing amounts of foundation sand between the impervious blanket and bedrock, using the levee size and seepage length based on the FS. Based on those parameters, an acceptable factor of safety of 1.6 at the landside levee toe could be obtained with a maximum 5.5-foot thick layer of pervious sand above bedrock.

Underseepage analysis will be performed as we progress through design. A subsurface investigation, including soil borings and laboratory testing, will be used to support this analysis. The design water loading will be determined during the next design phase after review of the hydraulics and hydrology (H&H) model. The design will be bracketed with analysis up to the TOL loading.

4.4 SLOPE STABILITY

Limited global slope stability analyses were performed for the FS, with some results reported in the text of Appendix B and some software output and hand calculations included in Appendix B5-B. These included analyses provided by the original Architect-Engineering (AE) designer and later analyses by USACE.

4.4.1 Architect-Engineer Feasibility Stability Analyses

Stability was analyzed for breach surfaces including the new levee structure and the existing channel at three cross sections considered to be the most critical. The levee or floodwall is not clearly defined in the cross sections in the software output; it is not clear that the new structures were considered in the analyses.

Stability was analyzed using the software program XSTABL, version 5.2, by Interactive Designs, Inc. The program was used to perform general limit equilibrium analysis using the Janbu and Bishop methods. Analysis of normal operating conditions assumed water surfaces approximately 5 to 8 feet below the TOL. For this condition, the minimum factor of safety was calculated as 4.3.

The XSTABL output shows that undrained soil shear strength was used for the analysis. Two soil layers were used, a stronger upper soil layer that extended approximately five feet below ground surface and a thicker lower layer extending from the bottom of the upper layer to the top of bedrock. The upper layer was modeled with a unit weight of 120 pounds per cubic foot (pcf), a cohesion of 2,000 pounds per square foot (psf), and a friction angle of zero. The lower layer was modeled with a unit weight of 115 pcf, a cohesion of 800 psf, and a friction angle of 0.

The three cross sections were also analyzed for sudden drawdown with a reported minimum factor of safety of 1.9. The sudden drawdown analysis output was not included in the report.

Chart-based hand calculations with limited documentation were also provided for the post-construction and sudden drawdown cases at one cross section, with factors of safety shown as 2.3 and 1.2, respectively.

The existing creek bank with the limestone-block retaining wall was analyzed for global stability at one cross section on XSTABL with the wall modeled as a third soil layer with a unit weight of 145 pcf, friction angle of 30 degrees, and cohesion of zero. The calculated factor of safety was 2.2.

Hand calculations with limited documentation were also provided for checking overturning and sliding of the limestone block wall at one cross section, with calculated factors of safety of 2.6 and 2.7, respectively.

4.4.2 U.S. Army Corps of Engineers Feasibility Stability Analyses

An evaluation of Atlas 14 precipitation impacts on the recommended plan was performed after the AE firm that developed the FS was released from contract. During the re-evaluation of the recommended plan, USACE, after additional conversations with the City of Merriam, Kansas and MDD, discovered the existing limestone-block retaining wall that supports the creek bank experiences regular breaches along the proposed levee system reach. When these breaches occur MDD rebuilds the section of breached creek bank. The wall is not considered capable of providing support to the proposed levee or floodwall.

USACE considered several alternatives to either stabilize the creek bank or provide a foundation for the project that does not rely on the bank's continued stability. The first option was to stabilize the creek bank, remove the existing creek bank wall, and replace it with a new modular gravity wall system (gabion basket wall, etc.). This alternative screened out due to excessive cost for construction in the wet and temporary shoring during construction.

Next, two alternatives were evaluated to provide a floodwall foundation that does not rely on the limestone-block retaining wall. While the alternatives do not rely on the existing limestone block wall for short-term stability, this solution relies on the MDD to continue making timely repairs to the limestone-block retaining wall. The exact operational requirements for length of time or conditions before scour affects stability of these alternatives was not defined in the FS. The two alternatives were to construct a secant drilled shaft floodwall or a floodwall supported on unreinforced auger cast piles.

Constructing a secant drilled shaft floodwall consists of installing overlapping drilled shafts to form a secant pile wall landward of the existing limestone block wall. The new floodwall would be an I-wall structurally tied to the drilled shafts. The lateral load capacity of a single drilled shaft proposed to be used in the secant wall was analyzed using Ensoft's LPILE software. A distributed lateral load was applied to the pile based on a 250 psf surcharge at the ground surface and vertical stress from the ground surface to top of bedrock. The analysis assumed the secant wall would not be supported by the existing limestone-block retaining wall or the soil between the retaining wall and the proposed secant wall. Bedrock was modeled as strong rock (vuggy limestone) with an effective unit weight of 82.6 pcf and an unconfined compressive strength of 2,000 psi. This alternative screened out due to higher costs of construction than other alternatives.

Constructing a floodwall supported on unreinforced auger cast piles is the recommended option from the FS and consists of 16-inch diameter, unreinforced concrete, soil replacement columns extending to the top of bedrock. The columns will be placed approximately 2 feet on-center in an equilateral triangle

pattern. The recommended width of ground improvement is 15 feet, centered on the floodwall footing. The recommended plan is based on MDD repairing the breached creek banks so that there will not be permanent ongoing scour of the improved ground supporting the floodwall. The exact O&M requirements for those repairs were not defined. The sketch included in Appendix G shows the floodwall footing extended to a 15-foot width incorporating the entire width of ground improvement. The auger cast piles are unreinforced, and no connection was defined between the piles and the footing. The entire block was analyzed as a wall sitting on bedrock with composite properties for the improved soil. Hand calculations showed factors of safety of 1.3 for sliding and 3.9 for overturning.

4.4.3 Current Analyses

Limited levee slope stability analyses were performed for this report using parameters based on soil properties at other projects or textbook soil properties (see Appendix B.2). The FS states levees were used for the design where there was enough space for greater than 1V:2H slopes up from the creek bed to the levee toe. The FS used 1V:3H slopes for the levee embankment above the top of channel.

Sudden drawdown stability for the riverside slope was analyzed for TOL loading using assumed soil strengths similar to those used for the Argentine Levee raise on the Kansas River near its confluence with the Missouri River (see Appendix B.2). Soil strengths used from the Argentine Levee raise are thought to provide a reasonable estimate of those anticipated to be found during the proposed subsurface investigation. Using these soil strengths and using levee parameters based on available information, sudden drawdown stability was checked for various slopes of a 13-foot tall channel below a 6-foot tall levee.

Analysis results (Table 4-2) suggest that levee cross sections with channel slopes of at least 1V:2H would have an acceptable factor of safety for sudden drawdown. In areas where the channel slope is less steep, the recommended factor of safety could be met with lower soil strengths.

Table 4-2. Sudden Drawdown Analysis Results

Channel Slope	Sudden Drawdown Factor of Safety (1.0–1.2 required)
1V:1H	0.6
1V:2H	1.1
1V:3H	1.3

Preliminary slope stability analysis of the landside slope was also performed for steady state seepage with TOL loading, and assuming soil strength from the Argentine Levee raise.

This analysis resulted in a factor of safety of 0.9 with a 6-foot tall levee with 1V:3H slope loaded to TOL. When a two-foot thick sand drain was added to the base of the landside slope, the factor of safety increased to 1.3, just under the recommended minimum of 1.4. When a small stability berm (3-feet wide by 5-feet tall) was also added, the factor of safety increased to 1.6.

For the recent design of the Argentine, Armourdale, and Central Industrial District Levee raises, sand drains were required to meet the recommended factor of safety of 1.4 for steady state seepage with TOL loading. Depending on impervious blanket thickness, sand drains and small stability berms may be required to meet the factor of safety for that loading for the Upper Turkey Creek levee. In areas with limited space, this could result in changing the cross section from levee to floodwall.

Sustained water loading leading to steady state conditions at top of levee is not expected to occur due to the flashy nature of Turkey Creek. The design water loading will be determined as we progress through design after review of the H&H model. The design will be bracketed with analysis up to the TOL loading

and will include sensitivity checks for at what water loading sand drains or stability berms would be required to maintain the required factor of safety. With a lower design water level, these features may not be required. These analyses will be done as we progress through design when additional information on subsurface conditions is available from soil borings and laboratory testing.

4.4.4 Future Analyses

The proposed levee and floodwall areas will be evaluated per the stability requirements of EM 1110-2-1913 and EM 1110-2-1902 for end-of-construction, steady-state seepage, and sudden drawdown conditions. Soil parameters will be determined after subsurface investigation and laboratory testing. Local stability requirements for floodwalls are discussed in Section 4.5, Structures.

The design water loading will be determined after review of the H&H model. The design will be bracketed with analysis up to TOL loading.

The proposed alternatives for supporting the floodwall without depending on the limestone block creek wall will be re-evaluated as we progress through design. Although soil improvement with auger cast columns was the recommended alternative in feasibility, it is noted that this solution depends on the sponsor performing timely repairs to breaches of the limestone block creek wall. Soil improvement provides short-term stability for the floodwall in the event of breach of the limestone block creek wall, but subsequent water loading in an unrepaired area could scour out the improved soil foundation and lead to breaches of the floodwall. If the soil improvement alternative is carried forward, O&M responsibilities and the consequences of not making those repairs quickly need to be clearly defined. A rough order of magnitude to construct the auger cast columns with floodwall are $5,000 per lineal feet. This cost does not account for the likely possibility of acquiring real estate to construct.

Although the secant pile wall alternative was noted to be too expensive during feasibility, the increased initial cost would be cost-shared between the sponsor and the federal government as part of the project. A floodwall supported by a secant pile wall would be robust and not depend on the limestone-block retaining wall being repaired. The feasibility report does not include the raw numbers for the cost comparison and does not consider the cost of the limestone-block retaining wall repairs in the comparison. A rough order of magnitude to construct a secant pile with floodwall ranges from $2,000-$20,000 per lineal feet due to varying depths to bedrock. These cost comparisons will be considered as we progress through deisng.

4.5 SETTLEMENT

EM 1110-2-1913 states evaluation of the amount of post-construction settlement that can occur from consolidation of the embankment and foundation may be important if the settlement would result in loss of freeboard of the levee or damage to structures in the embankment.

The EM states many districts overbuild a levee or berm by a given percent to account for anticipated settlement, both of the foundation and within the levee or berm fill itself. The EM references overbuild of five to 10 percent for semi-compacted fill, which is the anticipated degree of compaction for berms.

The FS did not include settlement analysis.

4.5.1 Current Analyses

Consolidation settlement of the new compacted embankment soil is assumed to be relatively insignificant. Limited settlement calculations were performed for settlement of the clay blanket due to construction of a new 6-foot tall levee using the consolidation parameters from the Argentine Levee raise (see Appendix B.3). This analysis resulted in approximately 1.6 inches of settlement below the new levee.

4.5.2 Future Analyses

Consolidation settlement of the clay subgrade soils due to construction of the new levee will be analyzed based on soil borings and consolidation testing. Settlement will also be evaluated in floodwall areas using

the floodwall load and footing size. An overbuild may be recommended to maintain the design level of flood risk reduction after settlement.

4.6 STRUCTURES

The 2015 Feasibility National Economic Development (NED) Plan recommended an inverted T-wall floodwall design with a base width of 10 feet and a stem stick-up varying in height up to 6.5 feet. The floodwall would be supported on a 15-foot wide bed of soil reinforced using unreinforced auger cast piles. A key will not be necessary for sliding as the base will be entrenched within the reinforced soil on the landside of floodwall (see Appendix G). The riverside of floodwall will be supported by the soil reinforcing and is weighed down by the soil. A stem and footing thickness of 18 inches and a minimum of 4,000 psi reinforced concrete, will provide the necessary strength capacity needed to withstand the 0.5 percent AEP (1/200-year event) flows.

4.6.1 Alternative—Secant Pile Floodwall

As discussed in the geotechnical section, the recommended plan floodwall dimensions indicate a floodwall base 10-feet wide and system height up to 6.5 feet. The feasibility report mentions that it considered a secant pile floodwall, but it was deemed too expensive, and the selected plan was chosen which calls for ground modified soils columns under the floodwall. The use of a full height secant pile floodwall should be investigated during design process. A decrease in floodwall footprint by up to 8 feet could be expected assuming a 24-inch diameter shaft. This decrease in footprint would be significant in terms of cost and the impact to affected nearby buildings. The project delivery team (PDT) will consider this alternative during design and a cost estimate completed for comparison purposes. The exposed height of the floodwall varies from 0 to 6.5 feet and, therefore, meets the criteria of an I-wall. Current I-wall criteria is provided in EM 1110-2-2502 Floodwalls and Other Hydraulic Retaining walls (August 2022).

4.6.2 Stability

FS criteria was partially based on EM 1110-2-2100 available at the time. The current design requirements for local stability are defined in EM 1110-2-2100. Section 3-2 of EM 2100 (2005) load condition categories. Table 4-3 shows a comparison of the local stability criteria used during feasibility and what is currently required by design. The comparison is for the unusual loading condition only which was the basis of the feasibility recommendations. The return period for both is greater than 10 years but less than 750 years for critical structures as discussed in EM 1110-2-2502 (2022). This is an unusual loading category for critical structures per Figure 6.1 of EM 1110-2-2502 and the load combination of Table 6.1 of EM 2502 must be applied during the floodwall design.

Table 4-3. Top of Levee Loading Stability Criteria[1]

	Feasibility	Design (Critical)
Flotation Min FS	1.2	1.2
Sliding Min FS	1.3	1.3[2]
Rotation (Percent Base in Compression)	75 percent	75 percent
Bearing	Min FS=3.0[2]	Min FS=3.0[2]

[1]Assumes “Well Defined” Site Information Category

[2]For Critical structure designation, typical of levee unit structure unless specifically determined otherwise.

The new structures recommended in feasibility were approximated for cost purposes, and, therefore, the changes to the stability criteria have minimal impact on the cost of the recommended new structures. The criteria have not changed from the FS to current analysis, so no changes are expected to be made to the floodwall.

4.6.3 Strength Design Parameters

For the FS, the structures were evaluated with the new levee and floodwall loads and load factors were required to meet EM 1110-2-2104 (dated 30 November 2016). Table 4-4 summarizes these load factors for design. The comparison is for the unusual loading condition only which was the basis of the feasibility recommendations. The return period for both is greater than 10 years but less than 750 years for critical structures as discussed in EM 1110-2-2104. This is an unusual loading category for critical structures per Table 3-1 of EM 1110-2-2104 and these load factors must be applied during the floodwall design.

Table 4-4. Top of Levee Loading Strength Criteria

	Feasibility	Design (Critical)
Load Factors (LF)	1.6	1.6

4.7 BRIDGES

The following sections present a summary of the preliminary analysis performed on the three bridges requiring relocation and/or modifications.

4.7.1 Merriam Drive Bridge RM 2.636 (Reach 3b-1)

The FS recommended adding 4.5-6.0 feet tall parapet walls on each side of bridge to raise the bridge walls and use them as part of the line of protection. As discussed in Section 3.1, other factors, such as verification of hydraulic surcharge loading, scour effects around the bridge footings and side slopes near abutments, channel alignment, and debris impact should be considered in design.

A 0.5 percent AEP (1/200-year) event is the more likely event the design will meet according to the design PDT. Preliminary analysis shows that a headwall of six feet in height will increase overturning and uplift loads acting on the bridge and the bridge will breach. Preliminary calculations show a 3.5-foot high headwall may be adequate for overturning and uplift to meet the EM 1110-2-2100 requirements. A 3.5-foot headwall would put the top of wall at (911.5 feet [1948 record drawings]+3.5 feet) 915 feet. The 0.5 percent WSE at the bridge would be approximately 917.21 feet with the addition of a calculated 1.94 feet of surcharge on the wall for a total of 919.5 feet at the bridge. At the 919.5-foot height, and with a parapet wall 3.5 feet in height, the 0.5 percent AEP flows would completely overtop and equalize uplift pressures and rotational forces at the bridge. Scour in and around the bridge footings and side slopes, and debris impact forces on the bridge would most certainly need to be considered during design. Therefore, the FS recommended plan will not work due to bridge stability concerns. If the top of protection is lowered below approximately 915 feet, it maybe be possible to include the bridge walls into the line of protection. If the existing bridge is not adequate to meet the mentioned design requirements, the sponsor should consider a new bridge at this location due to channel alignment, age, and height of the bridge in relation to the 0.5 percent AEP event which may be a better alternative from an engineering and economics view. A comparative cost analysis for the existing bridge to remain versus building a new bridge that adequately addresses all concerns should be considered during design. A parametric estimate of $3.5 million was estimated during the June 2022 cost and schedule risk analysis (CSRA).

4.8 UTILITIES

Kansas City District published draft guidance entitled, Piping Systems, with recommendations for construction of a piping system through a levee embankment or its foundation. This guidance, as well as the following engineering manuals, will be used as criteria for utility relocations during design:

- EM 1110-2-1913, Design and Construction of Levees
- EM 1110-2-2502, Floodwalls and Other Hydraulic Retaining Walls
- EM 1110-2-2902a, Conduits, Pipes, and Culverts Associated with Dams and Levee Systems.

Section 5.1 lists these engineering manuals.

NWK local guidance, entitled Piping Systems, is found at:

https://usace.contentdm.oclc.org/utils/getfile/collection/p266001coll1/id/7575

4.8.1 Crossings

The FS investigated known utilities within the recommended plan's project area. The recommended methodology for storm structure relocations has changed since the FS (see Section 3.4). The methodology for the remaining utility relocations has not changed since the FS; however, relocations are expected to be modified during design as data for utilities is incomplete. Working with the real estate section, the PDT will re-evaluate the existing utilities and any additional utilities found with the updated survey or through data gathering. As noted in Section 2.4.1, numerous private storm water lines are assumed to exist within the project area based on site observations of small diameter pipes daylighting into Turkey Creek. Private storm water lines were not identified within the FS. Private storm water lines within the project area will be evaluated as we progress through design.

Table 4-5 details criteria for pipelines crossing levees to be reviewed during design.

*Table 4-5. Criteria for Pipelines Crossing Levees**

Pipelines	Leaving Existing Pipeline in Foundations of Proposed Levees	New Pipeline Installation	
		Pipes Through Levees	Pipes Over Levees
Must be known to be in good condition	X		
Must have adequate strength to withstand levee loading	X	X	
Must have adequate cover as needed to prevent damage by vehicular traffic or heavy equipment			X
Must have adequate cover for frost protection			X
Must have sufficient flexibility in joints to adjust under expected settlement and stretching of pipe	X	X	X
Pressure lines must have provisions for rapid closure in event of leakage or rupture	X	X	X
Gravity discharge pipes must have provisions for emergency closure in event of inoperative flap valves on riverside end	X	X	
Must have pervious backfill under landside third of levee where:			
a. Foundation materials are susceptible to piping	X		
b. Levee materials are susceptible to piping		X	

*Table 8-1 of EM 1110-2-1913

4.8.2 Uplift

The FS did not investigate utilities within the critical area for uplift concerns. Uplift will be analyzed during the design phase to assist in determining recommendations for utilities.

4.9 ROADWAYS

Roadway modifications are anticipated to be required to accommodate the construction of the proposed project. The design will consider impacts to the existing roadways within and adjacent to the proposed project. Table 4-6 shows anticipated roadway modifications.

Table 4-6. Anticipated Roadway Modifications

LB and/ or RB	Roadway	Anticipated Modifications
LB	Frontage Road	No modifications anticipated.
RB	Merriam Drive	Roadway repair of Merriam Drive after the installation of a culvert. Modification of Merriam Drive at the southwestern intersection of Johnson Drive and Merriam Drive may be required to accommodate adjacent floodwall. Modification of Merriam Drive adjacent to proposed detention basin may be required for access.
LB	West 62nd Terrace	Modification of West 62nd Terrace may be required to accommodate adjacent floodwall.
LB and RB	West 62nd Street	Access to Streamway Park Trail may be eliminated of modified along the LB.
LB	Knox Avenue	Modifications of Knox Avenue may be required to accommodate adjacent levee.
RB	Merriam Lane	Modification of Merriam Lane may be required to accommodate adjacent floodwall.
LB and RB	West 61st Street	Campbell Park—Streamway Park access may be eliminated or modified at LB. Access ramp to RB levee may be constructed and accessed via West 61st Street
LB	Campbell Street	Modification of Campbell Street may be required to accommodate adjacent floodwall.
LB	West 60th Street	No modifications anticipated.
LB and RB	Johnson West	Modification of Johnson Drive may be required to accommodate a closure structure (anticipated stoplog gap) east of the Johnson Drive Bridge.
RB	Kessler Lane	No modifications anticipated.
RB	West 58th Terrace	No modifications anticipated.
RB	Hocker Drive	Modification of Hocker Drive (currently access to a parking lot) may be required to accommodate adjacent levee.
RB	West 58th Street	No modifications anticipated.
RB	West 57th Street	No modifications anticipated.

4.10 SITE ACCESS CONSIDERATIONS

Site access will continue to be evaluated during the design. As the proposed project is within a fully developed urban area of Merriam, Kansas, parallel to I-35, site access is restricted and will require coordination with various stakeholders. Stakeholders include the City of Merriam, Kansas, MDD, commercial properties, and private properties.

Several segments of the existing Turkey Creek and Turkey Creek Streamway Trail within the recommended plan's project area are not within property owned by the City of Merriam, Kansas or the MDD. During design we will evaluate access and ownership for areas where routine operation and maintenance of the project will be required (see Section 4.12 for further discussion on real estate).

The CSRA performed within the FS estimated site access restrictions due to tight corridor work could reduce production rates by 20 percent, which is a key cost risk driver of the project. By continuing to evaluate site access during the design phase, this key risk driver can be further mitigated.

During design we will consider ways to mitigate dust, mud, and debris on the construction sites and access roads throughout the design process. Dust control may have an impact on risk drivers such as production rates and overall project cost.

4.10.1 Access Roads

The FS indicated access roads to the project will stem from three urban corridors that connect I-35 to the project include. The corridors include:

- Shawnee Mission Parkway (Exit 228B) is the upstream project limit
- Johnson Drive is the approximate midpoint of the project
- Merriam Drive Bridge is the downstream project limit.

Site access will be further evaluated during design and could potentially utilize several streets that terminate adjacent to Turkey Creek. Table 4-7 lists these streets (from upstream to downstream).

Table 4-7. Access Roads

LB Roadway Access Options	RB Roadway Access Options
W. 61st Street (residential)	W. 62nd Street (commercial)
W. 60th Street (residential)	W. 61st Street (commercial)
Campbell Street (residential)	
Grant Street (residential)	

4.10.2 Access Ramps

Access ramp locations for levee access and creek access will be further evaluated during design. The PDT will also further evaluate limitations on crossing over existing sanitary lines that cross the Turkey Creek channel. The PDT understands that MDD currently will not cross sanitary lines in the channel with vehicles due to concerns for pipe age and low clearance over the pipes.

Per guidance in EM 1913, the following general levee access ramp considerations will be further evaluated during design:

- a minimum of one landside access ramp may be provided at each levee segment.

- If a levee segment does not have an entrance and exit ramp, a turnaround may be provided. (No turnouts are assumed to be needed as each levee segment is less than 2,500 feet.)

There is a total of seven levee segments within the FS recommended plan. Locations for access ramps to each levee segment were not identified in the FS. Table 4-8 summarizes the levee segments as well as access ramp considerations.

Table 4-8. Access Ramp Considerations

Levee Segment Details			Access Ramp Considerations
Approximate Station (Per FS)	**Approximate Length (feet)**	**LB or RB**	
3.65	180	RB	Limited layout options as access from Shawnee Mission Parkway and Merriam Drive is restrictive
3.595	320	LB	Potential access from West 62nd Street with turnaround at upstream end
3.495	1,034	LB	Potential access from West 62nd Street with turnaround at upstream end
3.48	240	LB	Potential access at West 61st Street with turnarounds at upstream and downstream ends
3.39	390	RB	Potential access at West 61st Street with turnarounds at upstream and downstream ends
2.97	1,051	RB	Potential access from West 57th Street with turnaround at upstream end
2.68	168	LB	Limited layout options as access from Merriam Drive is restrictive. Potential access from Merriam Drive with turnaround at upstream.

4.10.3 Construction Staging Areas

Construction staging areas will be further evaluated during design. The FS noted the Construction and Engineering Division staff determined two acres is adequate for construction staging. Four sites have been identified in the FS and will be further evaluated during design:

- Site 1: 0.7 acres northwest of the intersection of Merriam Drive and Turkey Creek. Access to this site is from Merriam Drive.
- Site 2: 2 acres at Merriam Marketplace and adjacent commercial property north to be acquired for the project. Access to this site is from Merriam Drive.
- Site 3: 2 acres including a park and adjacent residential property to be acquired for this project. Access to this site is from West 61st Street via Mastin Street and Shawnee Mission Parkway.
- Site 4: 3.6 acres bounded by Shawnee Mission Parkway and Merriam Drive. Access to this site is from Merriam Drive.

4.10.4 Access to Public Parks and Trails

The FS indicated the sponsor and the public have voiced concerns of potential impacts to the adjacent parks and trails. Parks and trails within and adjacent to the project to be considered during design include the following:

- Merriam Marketplace (facilities used for the Farmer's Market)
- Werner Park (LB located near West 57th Street and Knox Street)
- Campbell Park (LB located at West 61st Street and Knox Street)
- Turkey Creek Streamway Trail (LB from West 75th Street to Werner Park)
    - Farmer's Market Pedestrian Bridge at approximate RM 2.875 (connecting trail to Merriam Drive north of West 63rd Street)
    - Pedestrian Bridge at approximate RM 3.575 (connecting trail to Merriam Marketplace).

As we progress through design we will further evaluate accommodating public access to parks and trails. Approximately 2,285 feet of Turkey Creek Streamway Trail is riverside of the recommended LB levee/floodwall alignment. This long stretch of Turkey Creek Streamway Trail could be inundated quickly during flash flood events. During design we will assess if design modifications are necessary to provide adequate alerts and/or evacuation routes to this stretch of Turkey Creek Streamway Trail users during high water events.

Table 4-9 lists trail segments to be replaced or relocated per the FS recommended plan.

Table 4-9. Trail Segments Proposed for Replacement

Approximate Station Location (Per FS Stationing)	LB or RB	Trail Replaced or Relocated	Proposed Approximate Length to be Replaced or Relocated (feet)
Station 3.569	RB	Replaced	100
Station 3.569	LB	Replaced	370
Station 3.349	LB	Relocated	100
Station 3.250	LB	Replaced	700
Station 2.679	LB	Relocated	200*

*200 feet will be demolished; 250 feet is required to be relocated to provide levee crossing.

4.10.5 Access to Private Property

Access to private property will be required to construct the recommended plan. Private property within the recommended plan's project footprint may have permanent impacts to their current access conditions. The following impacts to private property during and after construction will be further assessed during design:

- Access ramp location impacts (potential impacts to properties with proposed levee segments)
- Impacts to private parking (potential impacts to the western extents of commercial properties along the RB)
- Impacts to loading dock access (potential impacts to 6230, 6234, 6236, and 6240 Merriam Drive).

4.10.6 Traffic Control

Traffic control will be further evaluated during design. Traffic control will include vehicular and pedestrian plans and include re-routing of pedestrian traffic along Turkey Creek Streamway Trail during certain phases of construction activities. Coordination between the sponsor, commercial properties, residential properties, and the public will be required.

4.11 BORROW

No borrow sources were identified during FS, and a subsurface investigation was not performed for any proposed borrow location because it was determined that the volume needed for this project would be small enough that it would be more cost-effective to use a commercial borrow source. This will be investigated again during design, to determine if this remains accurate, or if it is more cost-effective, or reduces project risk to include a borrow source with this project.

4.12 REAL ESTATE

The City of Merriam, Kansas, owns fee over approximately 7.5 acres along the project area. These lands are available for the project but are not sufficient to cover all improvements. The city has also granted the use of city parks in the area to mitigate tree loss. The MDD also owns fee over 9.2 acres along the channel and will be available for use on the project.

Required estates for project purposes outlined by FS will include permanent levee and flood protection easement, temporary work area easements, fee acquisition, and utility easements. The entire project will affect 121 tracts. Parcels JP35000000-0009, JP28000033-0024D and JF241212-3006 will need to be acquired in fee due to the location of the buildings and the need for space for the levee and/or floodwall. Parcel JF241212-3005 is where the detention basin will be constructed. The elevation of this property will be adjusted and will require removal of the building. No disposal action is needed for this project.

Parcel JF241212-3005, a commercial property, is the location of the proposed detention basin, which will require a fee acquisition. The proposed placement of flood control structures run through the center of parcel JP35000000-0009, a commercial property. Parcel JF241212-3006, a commercial property, has improvements near the current bank, leaving little room for construction of flood control structures. A small storage building is located within feet of the bank on parcel JF84000009-0001A, a commercial property. The shed will be the only structure removed from this property. The one residential property impacted is JP28000033-0024D. The flood control structures proposed run through the parcel and require a full acquisition. Total estimated costs for these five P.L. 91-646 relocations are $250,000.00.

The unidentified public utilities could be an issue as most of the areas of interest are currently heavily developed and have been so for close to one hundred years.

There are four properties that require fee acquisition and one shed that will have to be acquired. The estimated cost includes the estimate for the purchase of these properties and an estimated cost for P.L. 91-646 relocation costs of $9,645,342.00. This includes land acquisition; utility/facility relocation; and lands, easements, rights-of-way, relocations, and disposal area (LERRD) administrative costs.

4.13 HAZARDOUS, TOXIC, AND RADIOACTIVE WASTE

A records search for potential contaminated sites along the reach of Turkey Creek addressed by this DDR, was performed in 2009, and updated in 2015 and again in 2023. Based on the findings from the records search, there are no known superfund sites that will impact the proposed work. In addition, no solid waste facilities, such as former landfills, were identified at locations that would impact the project. There were several spills reported near Turkey Creek along the reach addressed by this DDR, but they were quickly remediated and should not have any significant impact to the project. There are six properties with current or former underground storage tanks (USTs), with the status of the tanks unknown on two of those properties, 5560 Merriam Drive, and 5745 Merriam Drive, no longer in use. There is no known existing contamination associated with any of the current or former tank locations, although some contamination was encountered and remediated when the tanks that were closed and removed.

Two areas of concern were discovered during a February 2023 soils investigations. Buried railroad tires, stained soil, and debris were discovered while advancing a boring on 5726 Merriam Drive. This may present foundation issues for the proposed levee along this reach as well as issues with construction of a retention basin proposed on this property. The other issue discovered during the February 2023 soil investigations was petroleum contamination located on City property just north of 5920 Merriam Drive at a

depth of 10 to 11 feet below the ground surface. Sample results indicated total petroleum hydrocarbon (TPH) levels above residential values for mid-range hydrocarbons but below non-residential levels. Volatile organic compound (VOC) analysis results were all non-detect, which suggests the source of contamination is very old and the underlying constituents driving the health-based TPH risk levels have degraded over time.

Overall, the risk of encountering significant environmental/hazardous, toxic, and radioactive waste (HTRW) impacts during construction appear relatively low based on Federal and State environmental records. However, there remains uncertainty about activities that occurred prior to Federal/State regulations being enacted and records kept. An example of this is the debris encountered at 5726 Merriam Drive and the petroleum contamination just north of 5920 Merriam Drive, both discovered during subsurface investigations performed in February 2023. Neither of these sites were expected to have contamination issues based on environmental records. It is not possible nor cost effective to identify all potential environmental subsurface issues along a greater than one mile portion of the channel addressed in this DDR. The density of borings and other investigative techniques would be both schedule and cost prohibitive due to the potentially isolated nature of contamination. Therefore, it is recommended that the contractor be required to develop contingency plans to address unexpected environmental conditions and contingency funding be set aside so unforeseen conditions can be addressed without significant project delays.

As for the two recently discovered sites with environmental concerns, 5726 Merriam Drive and just north of 5920 Merriam Drive, it is recommended additional investigations be performed to characterize the nature and extent of the environmental issues more fully on these properties. This will help to determine the engineering measures that should be included in the design and help refine cost impacts to the project. For the debris at 5726 Merriam Drive, it is likely all debris below the proposed features will need to be removed and disposed of at a permitted facility. For the petroleum contamination encountered just north of 5920 Merriam Drive, based on the TPH levels, it does not appear any remedial activities would need to occur. However, it is good practice to segregate any contaminated soil from clean soil excavated and dispose of it at a permitted landfill rather than reusing the soil on site or at other project locations. In this case it would likely be classified as a special waste that could be disposed of in a Resource Conservation and Recovery Act (RCRA) Subtitle D landfill, which is the type of landfill that accepts typical household waste.

There were no sites of HTRW concerns identified south of 61st Street within the limits of proposed DDR activities.

Refer to Appendix D for more detailed information on specific sites identified and figures showing the location of the properties of concern relative to project features.

4.14 ENVIRONMENTAL CONSIDERATIONS

As described in the FS and Environmental Assessment (EA), approximately 3.6 acres of trees would be removed to implement project designs. Based on the fox squirrel habitat suitability index modeling 2.7 average annual habitat units would be required in compensation. Mitigation requirements could be accomplished through a mitigation bank/in-lieu fee or planted on-site/in-kind within the watershed. In-kind mitigation would be accomplished by planting 185 hard mast producing trees over a 7-acre area, as this type of mitigation would closely replicate the open-canopy mast producing trees with little underbrush habitat that would be lost. This acreage was determined with the fox squirrel habitat suitability index model.

Other pertinent environmental considerations include threatened and endangered species, environmental justice, and cultural resources due to the timespan of the study and EA and current phase of the project. A search of the U.S. Fish and Wildlife Service (USFWS) Information and Planning Consultation webpage indicates the listing of the northern long-eared bat (endangered), Mead's milkweed (threatened), and the monarch butterfly (candidate) in addition to the pallid sturgeon that was assessed in the project's EA. Therefore, additional coordination with the USFWS may be required. Coordination with USFWS may determine that potential impacts to some or all these species are negligible. Additionally, while the

project's EA evaluated potential environmental justice impacts, there have since been updated requirements, guidance, and resources for analyzing these impacts. Reevaluation of environmental justice impacts will likely be necessary to confirm if there are any previously unconsidered effects. Furthermore, a review of archeological sites and/or architectural resources listed in or eligible for the National Register of Historic Places (NRHP) would be required as well as consultation with the Kansas State Historic Preservation Office (SHPO) and relevant federally-recognized Native American Tribes. Once the project area has been defined, field survey may be required to evaluate the potential for intact cultural resources, including architecture.

4.15 PRELIMINARY COST ESTIMATE UPDATE

As part of this FS validation effort, the cost estimate from the FS was escalated to today's prices. The PDT also performed an initial CSRA. As the project reaches 35 percent design completion, the cost estimate will be updated based on findings within this document. See Appendix H for more information.

4.16 ADDITIONAL DATA REQUIREMENTS

Below is a summary of all the additional data the PDT will collect as 35 percent design completion is reached.

4.16.1 Topographic and Real Estate Survey

An AE survey task order has been awarded to provide a topographic survey of the project area, as well as ground penetrating radar (GPR) surveys to properties suspected of having USTs within the project limits. The survey began in February 2023 with a final survey deliverable is expected in July 2023.

As part of this project, USACE will complete the boundary survey of the adjacent properties for use in design.

4.16.2 Subsurface Investigation

Boring logs are available for two historical borings drilled within the current project area. As part of the FS, an Integrated Environmental Assessment included investigation 20 square miles of the Upper Turkey Creek watershed. Several pilot borings were conducted along Turkey Creek with the majority placed near the Kansas River located at U.S. 69 Highway and I-35 and eastward. Two borings drilled in 2002, labeled DC-4 and DC-5, were conducted in the current project area.

These two soil borings revealed mostly silty clay fill and weathered shale to auger refusal on limestone at approximately 13 feet below ground surface. The subsurface investigation continued with rock coring to between 25.9 and 27.6 feet below ground surface.

Additional subsurface soil investigation and laboratory testing of soil samples were recommended as part of the design. These additional soil borings were performed to define the soil stratigraphy and depth to bedrock for the project area for underseepage, slope stability, bearing capacity, and settlement calculations. The borings were also performed to provide Standard Penetration Test (SPT) blow counts to estimate soil strength and disturbed and undisturbed samples for laboratory testing.

It was recommended that 17 soil borings be conducted along the proposed levee system alignment. Borings were to be drilled to auger refusal on bedrock, expected at 12- to 15-feet below grade. Disturbed soil samples were to be taken in glass jars at approximately every five feet in depth. Approximately 20 relatively undisturbed Shelby tube samples were to be taken. Boring locations are shown in Appendix B.4. Boring and lab testing results will be included in future design documents.

4.16.3 Laboratory Testing of Soil Samples

The laboratory test results included in the FS are for soil samples taken from areas that were part of the larger area reviewed during the FS that are outside of the current project area. These tests included

Atterberg limits and grain size distribution. The following laboratory tests were recommended as part of design:

4.16.3.1 Unified Soil Classification System

Performed in accordance with ASTM D2487, Standard Practice for Classification of Soils for Engineering Purposes, including testing for grain size, moisture, and Atterberg limits. Soil classification will be used to determine material types for underseepage, slope stability, bearing capacity, and settlement calculations. For underseepage calculations, this will allow permeability ratios and elevations of impervious and pervious blanket materials to be assigned. It is estimated that 34 samples will be tested for USCS soil classification.

4.16.3.2 Moisture Content Test

Performed in accordance with ASTM D2216, Standard Test Method for Laboratory Determination of Water (Moisture) Content of Soil and Rock by Mass. Moisture content is used in global slope stability, bearing capacity, and settlement calculations. It is estimated that 34 samples will be tested for moisture content.

4.16.3.3 Soil Dry Unit Weight Test

Determined on relatively undisturbed cohesive soil samples from five-inch diameter Shelby tubes in accordance with the requirements in EM 1110-2-1906, Appendices I and II. Soil unit weight is used in underseepage, global slope stability, bearing capacity, and settlement calculations. It is estimated that ten samples will be tested for unit weight.

4.16.3.4 Consolidated Undrained Triaxial Shear Strength Testing with Pore Pressure Measurements (R bar test)

Performed on relatively undisturbed cohesive soil samples from nominal five-inch diameter Shelby tubes in accordance with ASTM D4767, Standard Test Method for Consolidated Undrained Triaxial Compression Test for Cohesive Soils. Consolidated undrained (CU) test results will be used to assign shear strength for cohesive soil for steady state seepage analysis and for rapid drawdown analysis. It is estimated that five CU tests will be performed.

4.16.3.5 Unconsolidated Undrained Triaxial Shear Strength Testing

Performed on relatively undisturbed cohesive soil samples from nominal five-inch diameter Shelby tubes in accordance with ASTM D2850. Unconsolidated undrained (UU) test results will be used to assign shear strength for cohesive soil for end of construction analysis. It is estimated that three UU tests will be performed.

4.16.3.6 Direct Shear

Performed on disturbed cohesionless soil samples, remolded to assumed field density in accordance with ASTM D3080, Standard Test Method for Direct Shear Test of Soils Under Consolidated Drained Conditions. Direct shear results will be used to assign internal friction angles for sands for stability analyses. It is estimated that three direct shear tests will be performed.

4.16.3.7 Consolidation Testing

Performed on relatively undisturbed cohesive soil samples from nominal five-inch diameter Shelby tubes in accordance with ASTM D2435, Standard Test Methods for One-Dimensional Consolidation Properties of Soils Using Incremental Loading. Consolidation testing will be performed on cohesive soils in the embankment and the pervious blanket to estimate the anticipated settlement due to the levee construction. It is estimated that five consolidation tests will be performed.

4.16.3.8 Unconfined Compression of Rock Core

Performed on rock cores in accordance with ASTM D2938, Standard Test Method for Unconfined Compressive Strength of Intact Rock Core Specimens. Unconfined compression strength of rock will be used for evaluation of various alternatives to support the floodwall on bedrock therefore not relying on the limestone block creek wall for support.

B.1 Underseepage
B.2 Stability
B.3 Settlement
B.4 Boring Locations

B.1 Underseepage Notes

Analyzed vertical underseepage gradient for proposed Upper Turkey Creek levee based on current information and assumptions as detailed below:

Existing Topography – Initially used cross section information from AE Feasibility Study analysis at River Mile 2.813 as that was judged in the study to be a critical area. Information was difficult to interpret, so supplemented with Google Earth at approximate River Mile 2.825 and other assumptions. Per Google Earth, prevailing landside grade in that area is approximately EL 905 ft.

Levee Cross Section – Feasibility Study stated that max levee height is 6 feet (assumed 6 feet from prevailing landside grade). Assumed 6 ft tall levee with 10 ft crown and 1V:3H side slopes down to EL 905. Measured 16 feet from EL 905 on the riverside to the creek bank.

Levee Subsurface Profile – Based on Borings DC-4 and DC-5, the two borings completed in the area of the current project during Feasibility, impervious blanket is continuous to bedrock. In other areas, a zone of foundation sand may exist between the impervious clay blanket and bedrock. Even if the impervious blanket is continuous to bedrock throughout the levee unit, vertical underseepage pressures may build up through joints and seams in the bedrock. This may be modeled as a zone of foundation sand. For sensitivity checks, moved blanket bottom up in profile, adding pervious sand blanket.

Underseepage was analyzed using the NWK underseepage spreadsheet based on blanket theory. SEEP/W seepage analyses were calibrated to the results of the spreadsheet and then used as parent analyses to provide pore water pressures for SLOPE/W stability analyses.

Table B.1-1: Underseepage Spreadsheet Parameters

Blanket Unit Weight	115 pcf, based on value used for similar soil at other projects
Top of Levee Elevation	911 ft, set to 6 ft (max levee height) above prevailing landside grade of 905 feet at cross section
Riverside Ground Elevation	905 ft at riverside levee toe, set to match prevailing landside elevation
Landside Ground Elevation	905 ft, prevailing landside grade
Landside Tailwater Elevation	905 ft, same as landside ground elevation
River Blanket Bottom Elevation	Based on two borings, impervious blanket is continuous to bedrock. For sensitivity checks, moved blanket bottom up in profile, adding pervious sand blanket.
Land Blanket Bottom Elevation	Based on two borings, impervious blanket is continuous to bedrock. For sensitivity checks, moved blanket bottom up in profile, adding pervious sand blanket.
Top of Bedrock Elevation	Based on two borings, bedrock is located 12.5-12.9 ft below grade (EL 895.71 and 915.15). Used 13 ft below landside grade at cross section (EL 905-13 = EL 892).
Permeability Ratio	Boring logs showed silty clay. Using 400 based on 1962 MRD conference values.
Riverside Seepage Length (L1)	Measured approximately 16 ft from EL 905 on riverside to creek bank
Levee Seepage Length (L2)	For 6 ft max tall levee with 10 ft crest and 1V:3H side slopes, levee width of 46 ft

B.2 Stability Notes

Evaluated levee slope stability for one assumed cross section

Existing Topography – Initially used cross section information from AE Feasibility Study analysis at River Mile 2.813 as that was judged in the study to be a critical area. Information was difficult to interpret, so supplemented with Google Earth at approximate River Mile 2.825 and other assumptions. Per Google Earth, prevailing landside grade in that area is approximately EL 905 ft.

Levee Cross Section – Feasibility Study stated that max levee height is 6 feet (assumed 6 feet from prevailing landside grade). Assumed 6 ft tall levee with 10 ft crown and 1V:3H side slopes down to EL 905.

Creek Bank – Measured 16 feet from EL 905 on the riverside to the creek bank at EL 892 for cross section on Google Earth. Used that for underseepage analysis and for steady state seepage check of landside slope. For sudden drawdown evaluation of riverside slope, checked 1V:1H, 1V:2H, and 1V:3H slopes from riverside levee toe to creek bed for sensitivity.

Levee Subsurface Profile – Based on Borings DC-4 and DC-5, the two borings completed in the area of the current project during Feasibility, impervious blanket is continuous to bedrock. Checked sensitivity of underseepage calculations to thinner impervious blanket (adding foundation sand between impervious blanket and bedrock). Results indicated satisfactory underseepage factor of safety could be obtained for up to 5.5 feet of foundation sand. Assumed 5 feet of foundation sand between bedrock and impervious blanket for stability calculations. The foundation sand did not appear to significantly impact the stability analyses as far as resistance to sliding. The higher vertical underseepage gradient due to the thinner impervious blanket; however, does have a significant impact on slope stability.

Underseepage Calibration – Using 5 feet of foundation sand results in hydraulic grade line (HGL, or water total head, as defined in SEEP/W) at bottom of blanket at landside levee toe of 909.03 ft on the underseepage spreadsheet. Calibrated the Geoslope model by adjusting saturated horizontal hydraulic conductivity for impervious blanket and impervious fill in SEEP/W until this HGL (water total head contour) was obtained at the landside toe. For this cross section, hydraulic conductivity of 7e-06 ft/sec was used for clay.

SEEP/W Boundary Conditions – A water total head equal to the top of new levee is applied on the riverward slope, and a water total head equal to the landside grade is applied to the landside edge of the model. A potential seepage face is applied to the landward levee slope with water rate equal to 0 ft^3/sec, and a no-flow boundary is placed at bedrock with a water rate equal to 0 ft^3/sec. Added a layer of foundation sand 0.1 ft thick above bedrock in the channel so that could have water total head boundary equal

to top of new levee in the channel and on riverside slope and still have no-flow boundary in bedrock on channel bed.

Riverward Extent of Model – Usually taken at least halfway into a river. For this analysis, used 40 feet, approximate full width of channel in this area.

Landward Extent of Model – Taken to 2,500 feet landward of the new levee centerline. Extending the boundary farther appears to have no influence on the calculation results.

Hydraulic Conductivity of Sand – Used 0.003 ft/sec. This value is typically used for NWK levees such as the Argentine Levee Raise on the Kansas River (see Argentine DDR), the floodwall modification project at South Topeka on the Kansas River (see South Topeka DDR), and for design of Missouri River levee L-476 (see DM-1, p. I-15). This is also within the typical range used in Das Principles of Geotechnical Engineering, Table 5.1, p. 164, 1998.

Permeability Ratio Check – A permeability ratio of K_f/K_b of 400 typical of ML-CL materials was used in the underseepage blanket theory spreadsheet. This equates to hydraulic conductivity of 7.5e-06 ft/sec for impervious blanket (K_b), using 0.003 ft/sec for sand (K_f). The 7e-06 ft/sec used for calibrating SEEP/W to the blanket theory spreadsheet results equates to a permeability ratio of 428.

Sand Drains – A 2 ft sand drain was placed at the base of the landside levee slope to improve the steady state stability factor of safety to the required 1.4.

Steady State Material Properties – Properties used for this preliminary analysis are based on soil properties used in the Argentine Levee Raise design. Material properties will be adjusted after lab testing is completed. Consolidated Undrained (CU) triaxial shear strength testing with pore pressure measurements will be used for selection of drained shear strengths for in-situ soils for steady state analysis. As it is not planned to identify borrow sources during design, strength properties for impervious fill will be assumed. The properties used in the current analysis are as follows:

Table B.2-1: Steady State Material Properties

Material	Unit Weight (pcf)	Cohesion (pcf)	Phi (degrees)
Impervious Fill (Embankment)	120	0	26
Impervious Blanket	115	0	26
Foundation Sand	115	0	32

End of Construction Material Properties – End of construction case has not been analyzed for this preliminary report. Unconsolidated Undrained (UU) triaxial shear strength testing will be used for selection of undrained shear strengths for in-situ soils for end of construction analysis.

Sudden Drawdown Material Properties - Properties used for this preliminary analysis are based on soil properties used in the Argentine Levee Raise design. Material properties will be adjusted after lab testing is completed. The effective stress plots of the Consolidated Undrained (CU) triaxial shear strength testing with pore pressure measurements will be used for selection of drained shear strengths for in-situ soils for steady state analysis/first stage calculations (Basic Strength on SLOPE/W). The total stress plots of the same test will be used for selection of undrained shear strengths for second stage calculations (R Envelope on SLOPE/W).

Table B.2-2: Sudden Drawdown Material Properties

Material	Unit Weight (pcf)	Basic		R Envelope	
		Cohesion (pcf)	Phi (degrees)	Cohesion (pcf)	Phi (degrees)
Impervious Fill (Embankment)	120	0	26	17	300
Impervious Blanket	115	0	26	17	300
Foundation Sand	115	0	32		

Sudden Drawdown Water Surfaces – Used top of levee for PZ1 and landside grade for PZ2.

SLOPE/W Settings – Pore water pressure conditions are taken from the parent SEEP/W analysis. Entry and exit point ranges were defined for the slip surface.

(Under Define Project/Advanced)
Analysis Type: Spencer
Minimum slip surface depth: 5 ft
Number of slices: 100
Maximum number of iterations: 100
Tolerable difference in FS: 0.001

(Under Define Slip Surface Entry and Exit Range)
Number of Increments over Range: 20
Number of Radius Increments: 20

Defining Slip Surfaces – Expanded limits of slip surface range if critical slip surface was at the edge of the range. After critical surface was determined, contracted limits of search around the critical surface to refine the search.

Failure Definition – For preliminary analyses, defined steady state failure as a slip surface including any portion of the levee crest. Also defined sudden drawdown failure as a slip surface including any portion of the crest.

B.3 Settlement Notes

Using assumed levee dimensions, soil profile from the two available soil borings, and soil parameters from Argentine Levee, maximum consolidation settlement of subgrade soils due to levee construction is estimated to be approximately 1.6 inches.

Settlement will be calculated during design using site-specific subsurface investigation and lab testing.

Assumptions and methods used for the initial calculations are given below.

Stress Increase – determined stress increase in clay blanket due to new embankment

H (levee height) = 6 ft max

Soil unit weight = 115 pcf

B1 = ½ crest width = 5 ft

B2 = slope width = 3*6 ft for 1V:3H slope = 18 ft

Consolidation Settlement – determined consolidation settlement of clay blanket due to new embankment

Assumed insignificant settlement within new embankment

C_r (Rebound Index) = 0.045 used Argentine value

C_c (Compression Index) = 0.32 used Argentine value

e_o (Initial Void Ratio) = 1.089 used Argentine value

Depth to Water = 13 ft below existing grade, used creek bed

Determined maximum past pressure based on overburden stress times overconsolidation ratio (OCR) rather than overconsolidation margin or unaltered preconsolidation pressure. This method has been used on several Kansas City District levee projects, including Dodson and Argentine.

OCR (overconsolidation ratio) – used chart developed from KC Levees testing (see Figure B.3-1)

This chart considered consolidation test data from Argentine as well as other Kansas River projects with similar soils, including Armourdale, CID KS, and Manhattan (see test data in Figure B.3-2). Adjusted depth of sample relative to landside grade (since many

borings went through the levee embankment) and modified overburden pressure relative to landside grade (zero at landside grade), adjusting the OCR. Omitted samples from the compacted embankment. Developed an OCR profile for OCR vs. Depth below LS Grade.

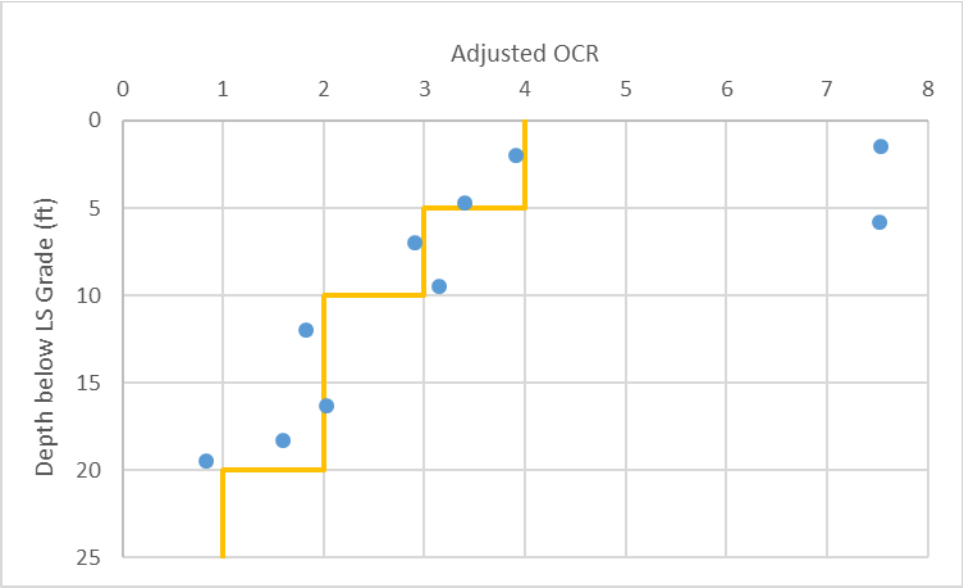

Figure B.3-1: OCR Profile

Used this OCR profile to develop maximum past pressures at various depths in consolidation calculations, multiplying the overburden pressure at that depth by the OCR for that depth.

Levee	Boring	Levee Station	Sample	Top of Boring EL	On crest? APPENDIX D
Hazardous, Toxic, and Radioactive Waste

ENVIRONMENTAL LAWS AND REGULATIONS

Various Federal and State legislation regulates the proper use, disposal, and clean up of hazardous materials and waste.

Resource Conservation and Recovery Act (RCRA)

Passed by Congress in 1976, this law gives the Environmental Protection Agency the authority to regulate hazardous waste disposal. This is accomplished by tracking the hazardous waste from its generation to its disposal. In 1984, there were several amendments made to this act, called the Hazardous and Solid Waste Act (HSWA). The amendments were enacted to include underground storage tank regulation, all releases of hazardous waste to the environment, and mandates for corrective action at hazardous waste facilities.

Toxic Substance Control Act (TSCA)

Also enacted by Congress in 1976, this law deals with all chemicals produced or imported into the United States. It requires that the chemical be adequately tested for toxicity prior to its commercial release to the public. In 1979, this act was amended to include the prohibition of the manufacture and distribution polychlorinated biphenyls (PCBs). PCBs are required to be labeled and disposed of properly. In the Statutes of Kansas, K.A.R. 28-55-5 states that PCB treatment, storage and disposal facilities shall comply with all applicable requirements of 40 CFR 761 subpart D, as in effect on November 1, 1986 and 40 CFR 264 subparts B, C, D, G and H, as in effect on November 1, 1986.

Comprehensive Environmental Response, Compensation and Liability Act (CERCLA)

Nicknamed Superfund, this law was enacted to start a trust fund for the payment of remediation at abandoned hazardous waste sites. This law was passed in 1980. The issue of abandoned or uncontrolled sites has grown through the years. The EPA manages the National Priority List, which lists certain CERCLA sites of the highest priority. By law, the State of Kansas also maintains a registry list of all abandoned and uncontrolled hazardous waste sites within the state. Superfund Amendments and Reauthorization Act (SARA) amended CERCLA in 1984. The amendments included more state and community involvement in the remediation process, increased focus on human health problems posed by contaminated sites, selection of remedies that permanently cleaned the site, and consideration of standards and other requirements in State and other Federal laws and regulations.

Federal Facility Compliance Act (FFCA)

In 1992, Congress passed the Federal Facility Act, which requires the Department of Energy (DOE) to develop and submit Site Treatment Plans for the development of capacity and technologies for treating mixed waste. All facilities that the DOE stores or generates these wastes must have such a plan. It also requires schedules for bringing new treatment facilities into operation.

State Regulations

The State of Kansas provides regulations for the use, management, and disposal of hazardous waste. These regulations are found in Article 31 on Hazardous Waste Management with additional statutes on Public Health in Chapter 65 and Hazardous Waste in Regulation Article 34. Environmental Use Controls are mentioned in K.S.A 65-1, 221 to 65-1, 235 and gives the state authority to assist existing programs to help address environmental contamination in a cost-effective manner and restrict the use of land where controls exist. It also empowers the State to enforce the regulations, defines hazardous waste, and controls the management, treatment, and disposal of hazardous waste. Statute Article 34 Solid Waste and Regulation Article 55 establishes criteria for facilities that handle and dispose of PCB waste. Article 28 contains regulations pertaining to the protection of surface waters and the water supply from environmental contamination and establishes water quality standards.

RECORDS SEARCH

A records search for potential contaminated sites along the reach of Turkey Creek addressed by this DDR, was performed in 2009, and updated in 2015 and again in 2023. The records search consisted reviewing various Federal and State of Kansas databased for past and present environmental activities and enforcement actions at properties adjacent to the creek. The information sources reviewed as part of this records search included:

- USEPA Enviromapper - GIS database identifying Superfund sites, sites were hazardous releases have occurred, and facilities regulated by the USEPA that handle materials designated as hazardous waste.

- USEPA CERCLIS Database - The Comprehensive Environmental Response, Compensation, and Liability Information System (CERCLIS) database contains general information on sites across the nation and US territories including location, status, contaminants, and actions taken. It provides information on sites being assessed under the Superfund Program, hazardous waste sites and potential hazardous waste sites.

- KDHE Identified Sites – Contaminated sites managed by the Bureau of Remediation (except for leaking underground or above ground petroleum storage tanks) are included in the Identified Sites List (ISL).

- KDHE AST and UST Assessment Database – this database provides information on site where leaks have occurred, or a tank has been closed.

- KDHE Database of Registered USTs

- KDHE Environmental Interest Finder – Kansas consolidated from the Identified Sites List, the AST and UST Assessment Database, and the Database of Registered USTs into an interactive online GIS system. Information in this system was reviewed in February 2023. A link to the KDHE interactive online GIS system is:

  https://maps.kdhe.state.ks.us/keif/

- USEPA Cleanups In My Community (CIMC) Map/Database – EPA and it's state, territory and tribal partners have developed a variety of cleanup programs to assess and, where necessary, clean up these contaminated sites. CIMC is intended to provide information about sites that might need to be cleaned up, are being cleaned up, or have been cleaned, in a particular community or anywhere in the United States. The scope of sites included in the CIMC GIS database are: Brownfields Properties, Brownsfields Grants Jurisdictions, RCRA Corrective Action, Superfund, Federal Facilities and Federal Agency Hazardous Waste Compliance Docket, Removals/Responses, and Recovery Act Funded Cleanups. The link to the CIMC Map/Database is:

  https://ofmpub.epa.gov/apex/cimc/f?p=cimc:MAP:0:::71:P71_WELSEARCH:AL|State|AL|||true|true|true|true|true|true||-1|sites|N|basic

FINDINGS

Below are the findings from the records search:

Superfund Sites

There were no Superfund sites identified in areas of potential soil disturbance.

Sites identified on CERCLIS Database

The CERCLIS Database identified no sites being investigated or remediated for hazardous waste within the areas of potential soil disturbance.

KDHE Identified Sites

There were no identified sites in the proximity of potential soil disturbance.

Solid Waste Facilities

There are no known solid waste facilities in the project area.

Registered and Closed Underground Storage Tanks (USTs)

There are six properties along the project reach that formerly or currently have USTs. These are described below, working from downstream to upstream.

- 5568 Merriam Dr, Merriam, KS
  State of Kansas records identify this location as either previously or currently having a tank. No other information is provided on the tank size or contents other than it is out of use. The proposed levee is approximately 75-ft from the building on the property and the location of the tank is unknown. If the tank on this property did have a past leak, there is the potential petroleum contamination may be encountered when excavating the inspection trench. It is recommend a boring be advanced in the location of the proposed levee to determine contaminated soil will need to be addressed during construction. See Appendix D, Figure D-1 for location.

- 5639 Merriam Drive, Merriam, KS
  This property contained one-300 gallon waste oil UST, a 10,000 gallon gasoline UST, and a 2,000 gallon diesel UST. This USTs and the associated distribution piping were removed. During removal, 20 CY of contaminated soil was removed near the 300 gallon waste oil tank and 150 CY of contaminated soil was removed near the gasoline and diesel tanks. This property also has two existing 10,000 gallon USTs that are in use. The presumed location of the existing tank is shown in Appendix D, Figure D-1. They were installed in 2019 and have all the latest protective measures to detect and contain any leakage. The potential of encountering petroleum contamination during construction of the proposed floodwall is believed to be low since contaminated soil was removed during closure of the older tanks. Due to the location of the existing tanks, it does not appear construction of the floodwall will be impacted.

- 5730 Merriam Drive, Merriam KS
  Three 560 gallon gasoline USTs were removed from this property. The KDHE records indicate no contaminated was encountered. (see Appendix D, Figure D-2 for location). The building associated with this property was demolished to develop the Farmers Market.

- 5745 Merriam Dr, Merriam, KS
  Kansas records indicate there was a UST on this property but status except to indicate it is out of use. The location, size, and former contents of the tank are also unknown. The property is more than 300 feet from the proposed levee, so it is unlikely there will be any impact to construction of the levee.

- 5903 Merriam Dr, Merriam, KS
  There are two 10,000 gallon gasoline USTs and one 8,000 gallon diesel UST being actively used on this property (see Appendix D, Figure D-3). This is no indication of past leaks from these tanks and they have spill basins, so it is unlikely contaminated soil will be encountered during installation of the proposed floodwall and gas main.

- 6032 Merriam Dr, Merriam, KS
  There was a 500 gallon waste oil UST removed from this property in 1990. Kansas records indicate the tank did not leak and there was not contaminated soil. Therefore, there is not expected to be any contamination encountered during installation flood wall near this property.

Spills

There were a number of spills report along the reach of Turkey addressed by this DDR. Most were associated with minor leaks of mineral oil from transformers and contamination associated with the spill was cleaned up. The only significant spill reported is described below:

- 61st and Merriam Ln, Merriam, KS
  On April 11th, 2022, and vehicle accident knocked down three utility poles and impacted four transformers. It was estimated that 91 pints of mineral oil from the leaked from the transformers and 95% of the oil went down a storm drain and into Turkey Creek. The oil did not contain Polychlorinated Biphenyls (PCBs), so it is not anticipated this was negatively impact construction of the proposed levee in this area. See Appendix D, Figure D-5 for location.

Other Areas of Concern

There were two areas of concern identified during investigations performed in February of 2023. A proposed levee crosses the west side of this property and it is also the location of a proposed retention basin. These are described below:

- 5726 Merriam Dr, Merriam, KS
  In February 2023 railroad ties and debris were encountered while advancing soil boring ADU-212 (see Appendix D, Figure D-2 for location). During advancing of a soil boring in February 2023, railroad ties and debris was encountered. The debris was described as having very poor strength properties as well has having a foul odor. The low strength properties may impact the foundation of the proposed levee and due to the foul odor would not be suitable for the base of the retention basin. All debris removed as part of the levee inspection trench and excavation of the retention basin will need to be disposed of in a permitted landfill. It is recommended additional investigation be performed to determine the nature and extent of the debris to assess the impact to the project.

- 5920 Merriam Dr, Marriam, KS
  In February 2023, petroleum contamination was encountered at a depth of 10 to 11 feet while advancing Boring ADU-201. The source of this contamination is unknown, however a historical aerial photo from 1941 shows a turn in and exit to the site with a small structure. It is speculated this may have been an former gas station but no records could be found. The current use of the property is auto repair. A soil sample was collected and tested for Total Petroleum Hydrocarbon (TPH) and Volatile Organics (VOCs). The results are in Table 1. The only range exceeding the KDHE Tier 2 RSK cleanup level of 250 mg/kg was the Mid Range Hydrocarbons at 316 mg/kg. However, this result is below the Non-Residential Scenario of 350 mg/kg. The VOC analysis was non-detect, which could suggest this is an old spill and the underlying constituents that drive risk associated with TPH have degraded. Since this is a non-residential property, the contaminated soil would likely not need to be cleaned up. However, it would be good practice to segregate contaminated soil during excavation and dispose of it in a permitted landfill. Most petroleum contaminated soil is classified as a Special Waste and typically can be disposed of in a RCRA Subtitle D landfill, which is the same type of landfill that accepts household trash. Additional testing would be necessary to meet disposal facility requirements.

Facilities Handling Hazardous Waste

There are a number of facilities located along the Turkey Creek channel that handle or produce hazardous wastes. These facilities are regulated by USEPA. Although they handle hazardous wastes, there have been no reported spills or areas requiring cleanup that would have an impact on the project.

CONCLUSION/RECOMMENDATIONS

Based upon the findings from the records search performed, there are no known Superfund sites that will impact the proposed work. In addition, no solid waste facilities, such as former landfills, were identified at locations that would impact the project. There were several spills reported near Turkey Creek along the reach addressed by this DDR, but they were quickly remediated and should not have any significant impact to the project. There are six properties with current or former USTs, with the current status of the tanks unknown on two of those properties, 5560 Merriam Dr and 5745 Merriam Dr. There is no known existing contamination associated with any of the current or former tank locations, although some contamination was encountered and remediated when the tanks that were closed and removed.

Two areas of concern were discovered during a February 2023 soils investigations. Buried railroad tires and debris were discovered while advancing a boring on 5726 Merriam Dr. This may present foundation issues for the proposed levee along this reach as well as issues with construction of a retention basin proposed on this property. The other issue discovered during February 2023 soil investigations was petroleum

contamination on 5920 Merriam Dr at a depth of 10 to 11 feet below the ground surface. Sample results indicated TPH levels above residential values for Mid Range Hydrocarbons but below non-residential levels. VOC analysis results were all non-detect, which suggests the source of contamination is very old and the underlying constituents driving the health-based TPH risk levels have degraded over time.

Overall, the risk of encountering significant environmental/HTRW impacts during construction appear relatively low based on Federal and State environmental records. However, there remains uncertainty about activities that occurred prior to Federal/State regulations being enacted and records kept. An example of this is the debris encountered at 5726 Merriam Dr and the petroleum contamination at 5920 Merriam Dr, both discovered during subsurface investigations performed in February 2023. Neither of these sites were expected to have contamination issues based on environmental records. It is not possible nor cost effective to identify all potential environmental subsurface issues along a greater than one mile stretch of the channel addressed in this DDR. The density of borings and other investigative techniques would be both schedule and cost prohibitive, due to the potentially isolated nature of contamination. Therefore, it is recommended that the Contractor be required to develop contingency plans to address unexpected environmental conditions and contingency funding be set aside so unforeseen conditions can be addressed without significant project delays.

As for the two recently discovered sites with environmental concerns, 5726 Merriam Dr. and 5920 Merriam Dr, it is recommended additional investigations be performed to more fully characterize the nature and extent of the environmental issues on these properties. This will help to determine the engineering measures that should be included in the design and help refine cost impacts to the project. For the debris at 5726 Merriam Dr, it is likely all debris below the proposed features will need to be removed and disposed at a permitted facility. For the petroleum contamination encountered at 5920 Merriam Dr, based on the TPH levels, it does not appear any remedial activities would need to occur. However, it is good practice to segregate any contaminated soil from clean soil excavated and dispose of it at a permitted landfill rather than reusing the soil on site or at other project locations. In this case it would likely be classified as a Special Waste that could be disposed of in a RCRA Subtitle D landfill, which is the type of landfill that accepts typical household waste.

There were no sites of HTRW concern identified south of 61st St within the limits of proposed DDR activities.

APPENDIX E
Hydraulics and Hydrology

APPENDIX E – HYDROLOGY & HYDRAULICS

E.1 Hydraulic Modeling Configuration & Parameterization
E.2 Feasibility Study Hydrology – Northeast Johnson County Watershed Study
E.3 Validation
E.4 Existing Conditions Comparison

E.1 Hydraulic Model Configuration & Parameterization

HEC-RAS version 6.3.1 was used for the two-dimensional hydraulic analysis. A graphic of the modeled mesh extent, calibration regions, and boundary conditions are presented in Figure 1.

E.1.1 Terrain

A LIDAR terrain surface collected in 2020 with a 2-foot cell size was provided by the sponsor and was used as the base mesh for the project site. A channel survey was performed by USACE personnel in December 2022 and January 2023. This survey was internally processed into station-elevation data and was used to generate a terrain surface with a 2-foot cell size using RASMapper. This survey was merged with the LIDAR terrain to provide a thorough representation of the Upper Turkey Creek channel and floodplain for modeling and mapping purposes corresponding with this project.

E.1.2 Mesh Development

The two-dimensional model consists generally of a 6.25-foot mesh within the stream channel, and a 25-foot mesh along the stream overbanks. A range of mesh sizes varying from approximately 3.125-25 feet were adopted. Smaller mesh sizing was generally adopted in areas of instability or where an increased level of detail is desired. Larger mesh sizing was generally adopted in areas of stability or lower hydraulic complexity or where a lower level of detail is acceptable. Hand-editing of the mesh was performed to aid in stability and to ensure that channel features and changes in channel or floodplain cross-section are properly simulated. Breaklines were placed at the toes of the right and left streambanks throughout Turkey Creek, at the approximate top-of-bank of the right and left streambanks, along the approximate centerline of tributaries, and along elevated roadway and railway embankments.

E.1.3 Bridge Modeling

No bridge drawings or schematics were identified in a literature review of the Feasibility Study documents or project directories to validate that the bridge and culvert cross-sections within the Feasibility Study are consistent with the array of structures that currently cross Turkey Creek within the project reach. Bridge drawings, stream crossing schematics, and/or surveys were obtained for 67th Street, Shawnee Mission Parkway, Johnson Drive, Merriam Drive, the DS Bus Lines bridge, the BNSF Trestle, the I-35 Antioch Road On-Ramp, and I-35 over Turkey Creek. Pedestrian bridges at 67th Street, near Shawnee Mission Parkway, and at the Merriam Marketplace were also incorporated in the modeling based on provided drawings. Each of these structures was transcribed via spreadsheet into the HEC-RAS bridge/culvert editor as a 2D connection. Each stream crossing structure was individually assessed, and modeling routines were adapted according to modeling validation efforts and the computed water surface profiles. Cross sections from the Feasibility Study were transcribed as profile lines to this analysis for comparison of water surface elevations. Bridge roughness values were assigned as 0.035 for the main channel region of each cross-section, and 0.04 for the overbank areas. Weir coefficient values of 2.0 were assigned for each stream crossing structure, as it is not anticipated that with each of these structures having guardrails or barriers that they will be hydraulically efficient in transmitting downstream flows once overtopped.

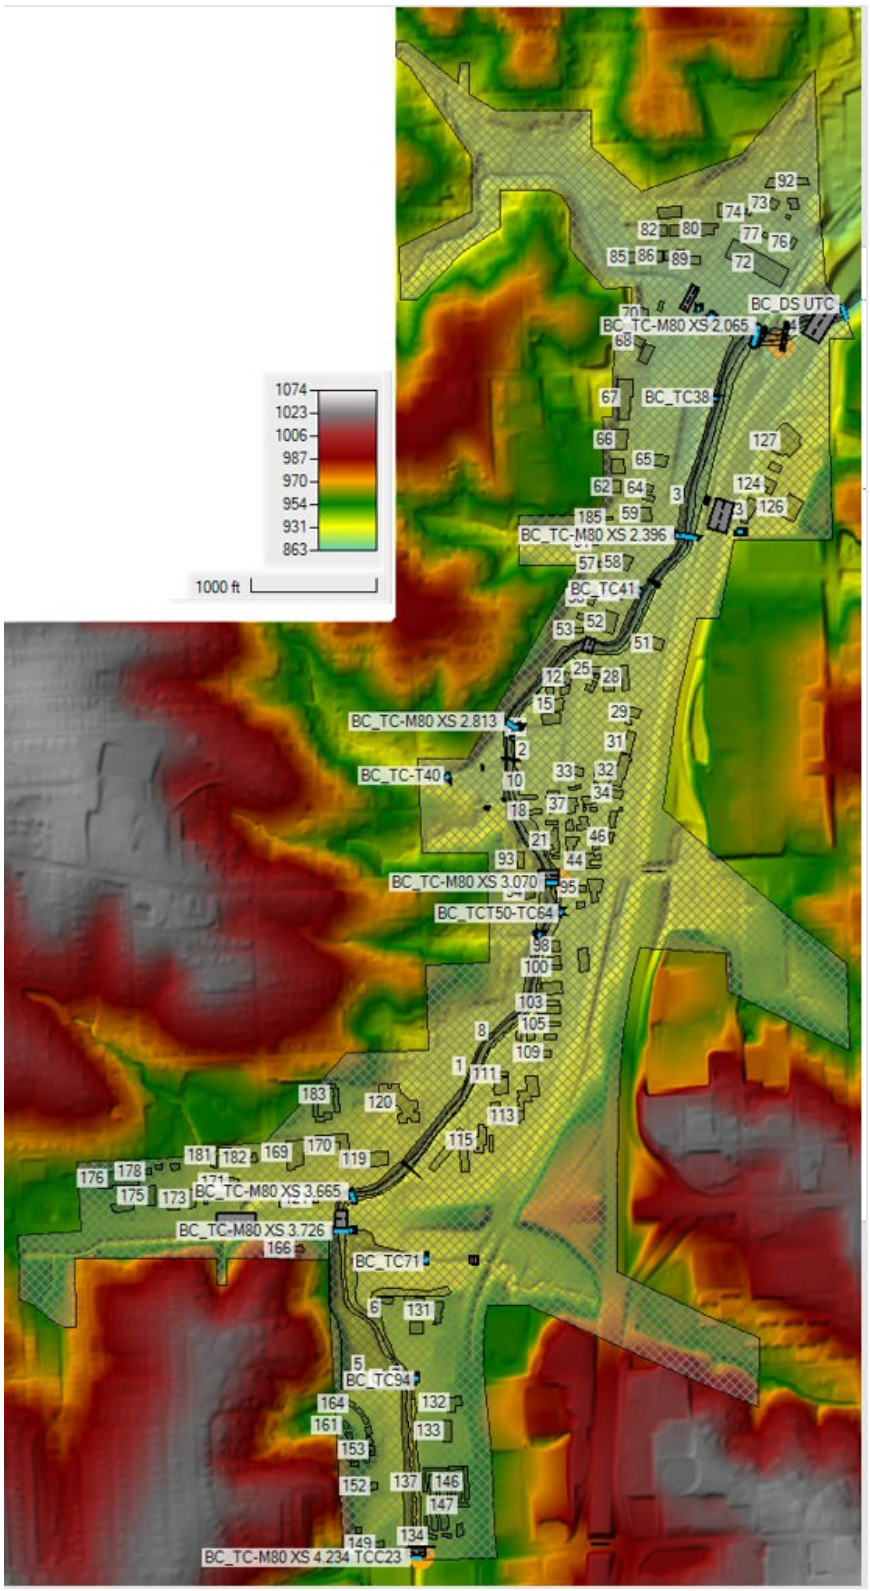

Figure 1. Extent of mesh (hatched area) with roughness calibration regions (gray numbered areas) and boundary conditions (light blue lines) identified. South (lower) end of image is 67th Street, and northeast edge (top right) is I-35.

The low flow methods adopted for each structure were selected by evaluating the presence of bridge piers, and then selecting the appropriate drag coefficient (C_d) based on the pier shapes according to the HEC-RAS Hydraulic Reference Manual. A drag coefficient (C_d) of 1.2 was selected for bridges with circular piers or rounded reinforced concrete box (RCB) inlets, while a C_d of 2.0 was selected for bridge piers or RCB inlets with a square upstream shape. The "Highest Energy Answer" for the low flow method was selected for use.

The high flow methods adopted for each structure were selected by evaluating the bridge deck shape and deck cover type and/or materials. Structures which were anticipated to experience a pressurization during a high flow due to a flat deck surface and a no through-deck ventilation to equalize the below deck pressure with the atmosphere were assigned with the "pressure and/or weir" high flow method. This generally included road bridges. Structures which were not anticipated to experience pressurization during a high flow due to a curved shape and/or due to spaced deck cover materials (e.g. spaced apart deck slats) were assigned with the "energy only (standard step)" high flow method. This generally included railroad trestles and pedestrian bridges. A summary of the bridge structures which cross Turkey Creek and their locations according to the Feasibility Study stationing are presented in Table 1.

A sensitivity analysis was performed for the high flow methods for only the pedestrian bridges and railroad trestle to examine the effect of the change to the water surface profile for the 1% and 0.5% AEP Atlas 14 unsteady flow events. A similar sensitivity analysis was not performed for the road structures due to the high confidence in their overtopping performance resulting in pressure and/or weir flow. This sensitivity analysis for the pedestrian and railroad bridges was performed due to the observed sensitivity of the water surface profile to the presence of bridge cross-sections within the flow conveyance area.

For the 1% AEP flow event, the difference in water surface profiles along the model stream alignment was within -0.04 foot at all pedestrian and railroad bridge locations, with the maximum observed value difference in the vicinity of the structure being -0.05 foot immediately upstream of the Shawnee Mission Parkway Pedestrian Bridge at model station 3.57. These values are within the uncertainty of the water surface profile. Anomalous differences in the water surface profiles at the DS Bus Lines Bridge (River Station 2.479) and Shawnee Mission Parkway Road Bridge (River Station 3.711), which are not pedestrian or railroad bridges, were observed and could not be explained. The difference between the two models was the high flow method at the pedestrian and railroad bridges only. In both cases, the differences are within +/- 0.14 foot which are also considered to be within the uncertainty of the water surface profile. A comparison of the water surface profiles and the computed differences in water surface profiles is presented in Figure 2.

For the 0.5% AEP flow event, the difference in water surface profiles along the model stream alignment was within -0.1 foot at all pedestrian and railroad bridge locations, with the maximum observed value difference in the vicinity of the structure being -0.1 foot in the immediate vicinity of the 67th Street Pedestrian Bridge at model station 4.238. These values are within the uncertainty of the water surface profile. Similar to the 1% sensitivity analysis, anomalous differences in water surface profile were observed at Merriam Drive and at the Shawnee Mission Parkway Road Bridge. In the case of the Shawnee Mission Parkway Road Bridge, the water surface profile immediately downstream of the bridge achieves a maximum difference of -0.29 foot, while immediately upstream of Merriam Drive, the water surface profile for the sensitivity analysis was -0.06 foot below the existing conditions water surface profile. A comparison of the water surface profiles and the computed differences in water surface profiles is presented in Figure 3.

In reviewing the sensitivity analysis profiles overlaid against one another within RASMapper, the differences at the pedestrian and railroad bridges were within the anticipated uncertainty of the

modeling at values of approximately +/- 0.1 foot or less. In the instances of the anomalous values at bridges that were not a part of the sensitivity analysis, the differences in value between the existing conditions and sensitivity analysis simulations are within a reasonable range. These anomalous differences could be due to a variety of factors, including the potential for 3-dimensional effects to flow due to the presence of the bridges, and the potential for debris or other non-aqueous objects within the stream. While debris or other objects were not simulated by the modeling, the sensitivity analysis validated that the adopted assumptions with respect to the high flow methods were reasonable, and that the adopted bridge modeling algorithms produce very similar results within the range of anticipated design profiles for the Upper Turkey Creek flood risk reduction project.

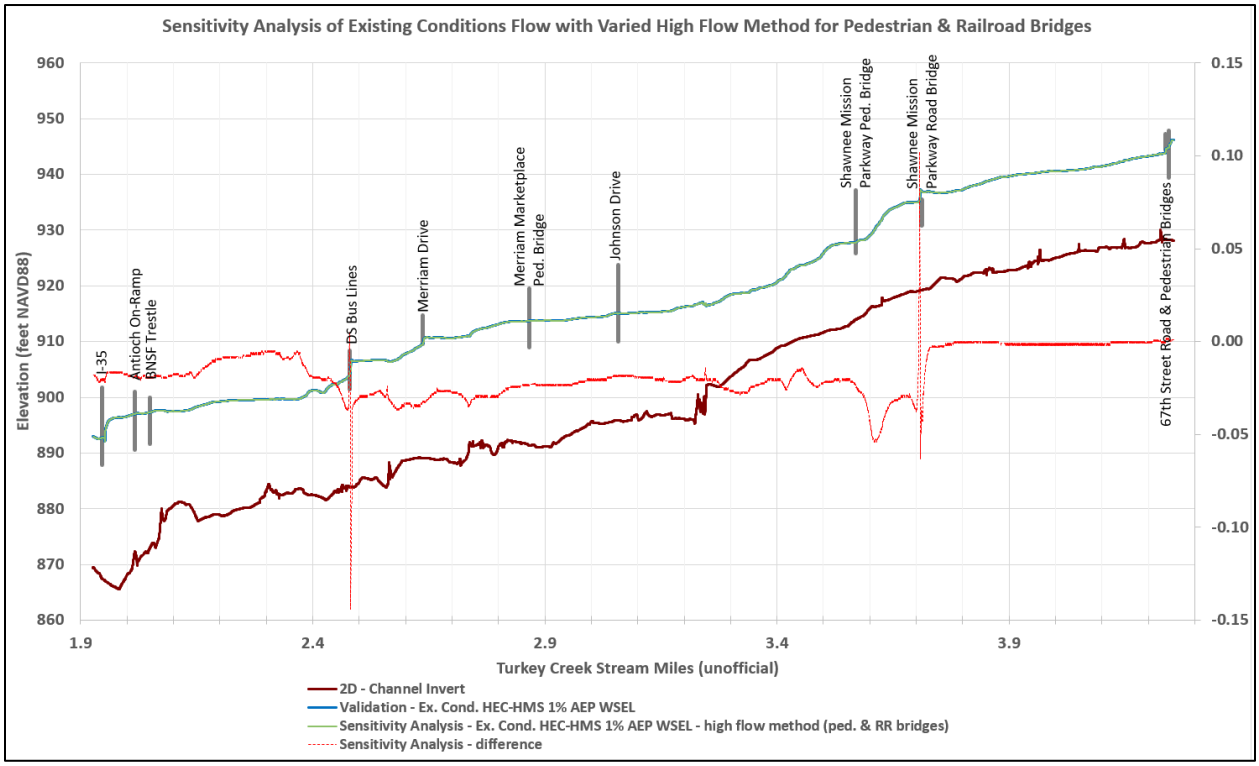

Figure 2. Sensitivity analysis of high flow methods for 1% AEP unsteady flow hydrograph for pedestrian & railroad bridges. Red line indicates difference between the existing conditions and sensitivity analysis water surface profiles, and y-axis difference values are along the right edge of the plot in units of feet. Left y-axis indicates maximum water surface elevation for both profiles. Brown line indicates the channel invert elevation along the stream model alignment, and its elevation is represented along the left y-axis.

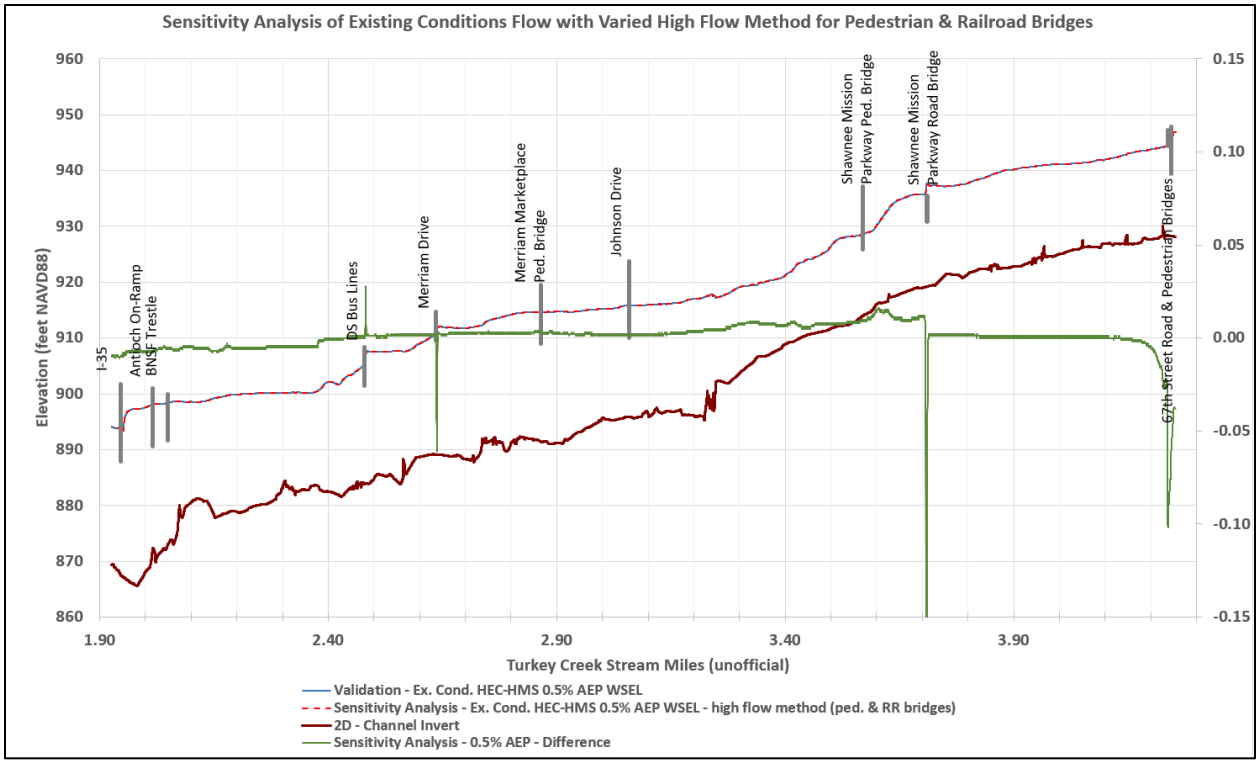

Figure 3. Sensitivity analysis of high flow methods for 0.5% AEP unsteady flow hydrograph for pedestrian & railroad bridges. Green line indicates difference between the existing conditions and sensitivity analysis water surface profiles, and y-axis difference values are along the right edge of the plot in units of feet. Left y-axis indicates maximum water surface elevation for both profiles. Brown line indicates the channel invert elevation along the stream model alignment, and its elevation is represented along the left y-axis.

E.1.4 Manning's Roughness Coefficients

A channel bed Manning roughness value of 0.035 and a streambank roughness value ranging from 0.04-0.045 were implemented as calibration regions based on the Feasibility Study modeling and validation with three 2017 flow events. Building structure footprints within the mesh area were identified and assigned a Manning's value of 0.2 to approximate the flow impedance these features are anticipated to represent during an out-of-bank flow event. This value is consistent with the values recommended for "Developed, High Intensity" description according to the 2D HEC-RAS User's Manual. Overbank roughness values were adopted based on the 2019 National Land Cover Dataset (NLCD), which is a digital raster file generated by the Multi-Resolution Land Characteristics Consortium (MRLCC)[1] that classifies land cover types. This digital raster file identifies land cover types based on specific ranges of light emissions returns from a range of sampling methods. Recommended Manning's roughness ranges for the specific land cover types classified by the NLCD dataset are presented in Table 2-1 of the HEC-RAS 2D User's Manual. The values adopted for this effort are presented in Table 2.

[1] The MRLCC is a group of federal agencies who generate land cover information at the national scale for a wide variety of modeling applications. Their website is https://www.mrlc.gov/.

Table 1. Summary of Bridges and Structures Crossing Turkey Creek.

Bridge Identifier	Feasibility Study River Station	Low Flow Method*	High Flow Method	Notes:
67th Street	4.244	Energy, Momentum (C_d = 1.2)	Pres. and/or Weir (Sub. Inlet + Outlet C_d = 0.8)	
67th Street Pedestrian Bridge	4.238	Energy (no piers)	Energy Only (Standard Step)	Not included in 1D model; walkway has gaps to equalize pressure if submerged
Shawnee Mission Parkway	3.711	Energy, Momentum (C_d = 2.0)	Pres. and/or Weir (Sub. Inlet + Outlet C_d = 0.8)	
Shawnee Mission Parkway Pedestrian Bridge	3.570	Energy (no piers)	Energy Only (Standard Step)	Not included in 1D model; walkway has gaps to equalize pressure if submerged
Channel Grade Control	3.23	N/A	N/A	Included in 2D model as a terrain feature
Johnson Drive	3.058	Energy, Momentum (C_d = 1.2)	Pres. and/or Weir (Sub. Inlet + Outlet C_d = 0.8)	
Merriam Marketplace Pedestrian Bridge	2.866	Energy (no piers)	Energy Only (Standard Step)	Not included in 1D model; walkway has gaps to equalize pressure if submerged
Merriam Drive	2.636	Energy, Momentum (C_d = 2.0)	Pres. and/or Weir (Sub. Inlet + Outlet C_d = 0.8)	
DS Bus Lines	2.479	Energy (no piers)	Pres. and/or Weir (Sub. Inlet + Outlet C_d = 0.8)	Surveyed; no plans available
BNSF Trestle	2.049	Energy, Momentum (C_d = 1.2)	Energy Only (Standard Step)	Bridge deck has gaps to equalize pressure if submerged
I-35 Antioch On-Ramp	2.016	Energy, Momentum (C_d = 1.2)	Pres. and/or Weir (Sub. Inlet + Outlet C_d = 0.8)	
I-35	1.946	Energy, Momentum (C_d = 1.2)	Pres. and/or Weir (Sub. Inlet + Outlet C_d = 0.8)	

* Highest energy answer adopted for all Low Flow Method computations

Table 2. 2016 National Land Cover Dataset (NLCD) values present within the simulated area, description, adopted Manning's roughness, and recommended ranges according to the 2D HEC-RAS User's Manual Table 2-1.

NLCD Value	Land Cover Description	Adopted Manning's roughness	Table 2-1 Recommended Range
11	Open Water	0.035	0.025 – 0.05
21	Developed, Open Space	0.035	0.03 – 0.05
22	Developed, Low Intensity	0.06	0.06 – 0.12
23	Developed, Medium Intensity	0.08	0.08 – 0.16
24	Developed, High Intensity	0.12	0.12 – 0.20
31	Barren Land Rock-Sand-Clay	0.027	0.023 – 0.030
41	Deciduous Forest	0.15	0.10 – 0.20
43	Mixed Forest	0.1	0.08 – 0.20
52	Shrub-Scrub	0.09	0.07 – 0.16
71	Grassland-Herbaceous	0.035	0.025 – 0.05
81	Pasture-Hay	0.035	0.025 – 0.05
82	Cultivated Crops	0.035	0.02 – 0.05
90	Woody Wetlands	0.08	0.045 – 0.15
95	Emergent Herbaceous Wetlands	0.06	0.05 – 0.085

E.1.5 Floodplain and Tributary Incorporation

Tributary stormwater culverts and/or conduits were implemented in select locations based on aerial imagery and approximate elevation and dimension measures were based on the LIDAR dataset and aerial imagery. These features were incorporated into the modeling to ensure that the volume represented by the tributary ditches and channels were attached to the Turkey Creek mainstem as they would be in the field. Surveyed elevations for these features were not collected, as detailed water surface profiles are not desired along the reaches of the respective tributary features, and the performance of the individual culverts and/or conduits is not being evaluated for this effort. During the site visit, no flap gates were identified on conduit and/or culvert features throughout the proposed project reach. As a result, conduits and culverts for the existing conditions simulations did not include any flap gates or closure features restricting backflow.

E.1.6 Boundary Condition Implementation and Sensitivity Analysis

The boundary conditions energy grade line (EG) slope values adopted for the Turkey Creek stream channel within the mesh were based upon the median value for the 50% through 0.5% friction slopes computed at the upstream (4.254) and downstream (1.927) cross-sections of the Feasibility Study 1-dimensional model. The median friction slope value was adopted based on the anticipated use of a varied flow hydrograph and the desire for the value to be representative throughout the simulation. The adopted upstream EG value was 0.004909, while the downstream EG value was 0.002583.

Boundary conditions for the modeling scenarios using the unsteady flow hydrographs were placed according to the cross-section stationing indicated in the Feasibility Study modeling, or near the node locations identified by GIS layers for the HEC-1 analysis. Cross-sections 2.065, 2.396,

2.813, 3.070, 3.665, 3.726, and 4.234 were adopted as boundary condition locations, consistent with the adopted flow change locations in the steady flow hydraulic modeling from the Feasibility Study. Similar to the upstream and downstream boundary condition locations, the median friction slope values for the 50% through 0.5% frequency events from the 1D Feasibility Study HEC-RAS model were adopted at the respective flow change cross-section locations.

The steady flow values corresponding with the 1% and 0.5% annual exceedance probabilities (AEP) indicated in the Feasibility Study model were implemented as constant flows within the Unsteady Flow Data Editor. Only these values were simulated as the design flow profile and levee/floodwall alignment were based on these values, respectively.

Unsteady flow hydrographs generated from the Feasibility Study hydrologic models were also simulated as part of the updated existing conditions analysis. Nodes from the hydrologic model identified as TCC23, TC94, TC-T71, TC-T59, TC66, TC-T50, TC64, TC79, TCT40, TC57, TC48, TC41, TC-T30, TC19, and TC38 were implemented as boundary conditions emptying into Turkey Creek according to their locations on Figure 6-1 of the “Northeast Johnson County Watershed Study” (2005). The EG slopes at the respective hydrologic node locations were based on the slope computed from the terrain approximately 10 to 25 feet upstream to downstream of the respective node location.

A sensitivity analysis of upstream and boundary conditions was performed to validate that the modeling extents are sufficient to not be significantly influenced by minor discrepancies in the adopted boundary condition slopes as compared to what exists for the reach of analysis. The sensitivity analysis consisted of three evaluations using an order of magnitude greater and less than the adopted value, as well as a decreased value within the same order of magnitude. The sensitivity analyses used upstream and downstream Turkey Creek EG slopes of 0.01 (BCTest1), 0.001 (BCTest2), and 0.0001 (BCTest3), and are presented in Figure 4.

The model was not particularly sensitive to variations in the upstream boundary condition EG slope; however, the model was highly sensitive to downstream boundary condition EG slopes less than those adopted for the modeling. The reach of analysis for the proposed levee and floodwall reach design, according to the cross-section reach adopted for the Feasibility Study, was from cross-section 3.665 (Station 3100 in Figure 3) at the upstream end to 2.594 (Station 8760 in Figure 3) at the downstream end.

Based on the sensitivity analyses, all three upstream water surface profiles approximately converge to within an absolute value of 0.1 foot difference from the existing conditions water surface by cross-section 4.05 (approximately Station 920 in Figure 2), which is upstream of the reach of interest at cross-section 3.665. At approximately cross-section 3.165 (Station 5750 in Figure 2), for the boundary condition EG slope an order of magnitude less than that adopted (BCTest3), the water surface profile diverges from the existing conditions profile and other sensitivity analyses by an absolute value greater than 0.1 foot. At approximately hydraulic model reach station 2.86 (Station 7360 in Figure 2), for the boundary condition EG slope of a similar order of magnitude as the existing conditions, but less than the adopted value (BCTest2), the water surface profile diverges from the existing conditions profile by an absolute value greater than 0.1 foot. At approximately hydraulic model reach station 2.478 (Station 9380 in Figure 4), for the boundary condition EG slope an order of magnitude greater than the existing conditions, the water surface profile diverges from the existing conditions profile by an absolute value greater than 0.1 foot.

Given the friction slope values computed by the Feasibility Study modeling, and the relative agreement of the water surface profiles for the sensitivity analyses with the existing conditions water surface within the reach of analysis, it is believed that the modeled reach extent is adequate to reasonably simulate the proposed Upper Turkey Creek flood risk reduction system.

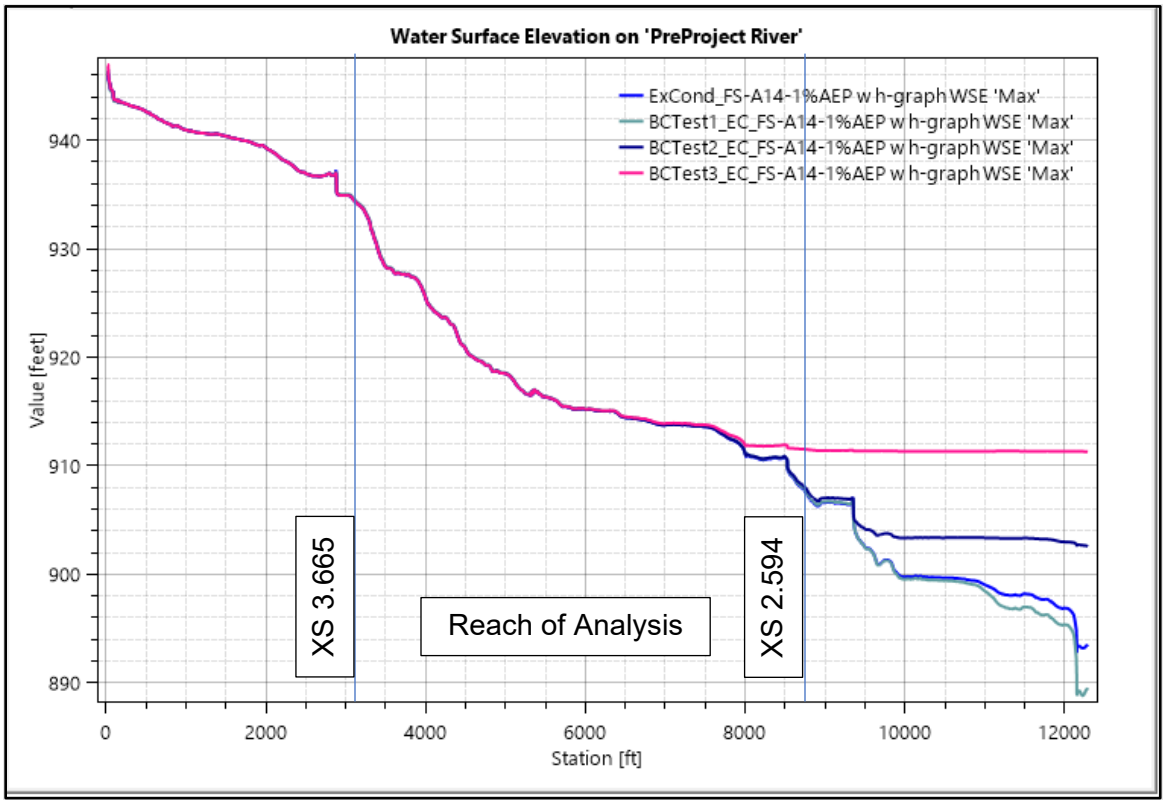

Figure 4. Comparison of boundary condition sensitivity analyses as compared to the existing conditions simulation (ExCond… with upstream EG = 0.002583 and downstream EG = 0.004909) simulations using an upstream and downstream boundary condition 1 order of magnitude greater than adopted (BCTest1 with EG = 0.01); 1 order of magnitude less than adopted (BCTest3 with EG = 0.0001); and within the same order of magnitude, but less than adopted (BCTest2 with EG = 0.001)

E.1.7 Stream Gauging

While no flow gauging is maintained on Turkey Creek, stage gauges are maintained at 67th Street, Johnson Drive, and at the Antioch Road On-Ramp for I-35. The 67th Street gauge is most upstream, while the Antioch On-Ramp gauge is the downstream gauge. Johnson Drive lies approximately halfway in between. These gauges are maintained as part of the Stormwatch gauge network by Johnson County, Kansas. Gauge datums were based upon the surveyed elevations from the current FEMA floodplain mapping effort. A summary of datums and stage adjustments for the purposes of analysis are presented in Table 3, while a map of the gauge locations is in Figure 4.

Table 3. Stormwatch Gauges used for analysis during hydraulic modeling with Stormwatch identifiers, datums and channel bottom stages.

Stormwatch Gauge Identifier	Gauge Location	Gauge Datum (NAVD88)	Channel Bottom Stage (feet)*
TU03	67th Street at Turkey Creek	928.06	2.15
TU04	Johnson Drive at Turkey Creek	895.418	1.65
TU06	Antioch On-Ramp at Turkey Creek	869.46	2.03

* Values are based upon documented measurements at Stormwatch website for the respective gauges.

E.1.8 Two-dimensional Modeling Algorithms and Parameterization

The adopted two-dimensional parameters used for simulation are presented in Table 4. In general, the default values were adopted. Notable exceptions to this include the Equation Set, Turbulence Model, and Matrix Solver parameters.

Due to the location of the project within a highly urbanized area, and some uncertainties with respect to the flow contributions of tributaries to the watershed, the SWE-ELM (original/faster) equation set was selected. The Diffusion Wave method was not anticipated to represent the momentum component of the flow analysis adequately, and the SWE-EM (stricter momentum) was believed to represent too high of a resolution and too lengthy of a computational time given the uncertainties in the precision of roughness values and the inability to reliably calibrate the model to recent flood events. The SWE-LIA (local inertia) equation set is useful for slow rising hydrographs or compound flooding where wind is important and cannot be simulated with the Diffusion Wave Equation. Turkey Creek is a flashy stream, and therefore, SWE-ELM was anticipated to represent the best available equation set option.

The Conservative Turbulence Model was selected to provide greater resolution with respect to the momentum components. Due to numerous features within the floodplain and crossing the channel, such as bridges, curves in the stream channel, in-channel features, and concrete encased pipes, it was anticipated that accounting for the momentum components would be critical to providing a more accurate water surface profile for selecting the appropriate flood risk mitigation measure for a highly developed area.

Longitudinal and Transverse Mixing Coefficient value defaults were adopted. This reach of Turkey Creek generally has gentle meanders and moderate surface irregularities, with some reaches of straight channel and relatively consistent cross-section. The default values are on the boundaries of the respective little- and moderate mixing descriptions in Tables 5.1 and 5.2 of the HEC-RAS 2D User's Manual and seem applicable to this analysis.

The SOR (Iterative) solver was not selected based on unsatisfactory results using the Pardiso solver. The FGMRES-SOR (Iterative) was not evaluated.

Table 4. Summary of adopted 2D simulation parameters for unsteady flow modeling

Parameter	Adopted Value
Theta	1
Theta Warmup	1
Water Surface Tolerance (ft)	0.01
Volume Tolerance (ft)	0.01
Maximum Iterations	20
Equation Set	SWE-ELM (original/faster)
Initial Conditions Time (hrs)	2
Initial Conditions Ramp Up Fraction	0.1
Number of Time Slices	1
Turbulence Model	Conservative
Longitudinal Mixing Coefficient	0.3
Transverse Mixing Coefficient	0.1
Smagorinsky Coefficient	0
Matrix Solver	SOR (Iterative)
Convergence Tolerance	0.00001
Minimum Iterations	3
Maximum Iterations	30
Relaxation Factor	1.3

E.2 Feasibility Study Hydrology – Northeast Johnson County Watershed Study

The Northeast Johnson County Watershed Study was completed in 2005 and provided the hydrology for the Feasibility Study. This analysis was supplemented using the same hydrologic modeling configuration within HEC-1 (and subsequently HEC-HMS) using Atlas 14 annual maximum series 24-hour total precipitation volumes. The hydrologic modeling for the Northeast Johnson County Watershed Study utilized the following parameterizations:

- Precipitation Quantity: KDOT published rainfall depths for 24-hour duration
- Precipitation Distribution: SCS 24-hour, Type II Distribution
- Surface Runoff Volume: SCS Curve Number
- Runoff Hydrograph: SCS Dimensionless Hydrograph
- Flow Routing:
    - Muskingum-Cunge (in streams and enclosed systems where backwater effects are negligible
    - Modified Puls (where significant flood storage is observed; used on selected lakes, detention basins, and upstream of selected bridges and culverts)
- Antecedent Moisture Condition: AMC 2.75 (calculated as AMC II plus 75% of the difference between AMC III and II)
- Subarea Delineation: Outfall locations at primary tributaries, primary crossings (i.e. roads), primary structures (i.e. dams) and the need to satisfy the 160-acre subwatershed drainage area goal for the project

E.3 Validation

A validation effort was undertaken using the 26-27 July 2017, 5-6 August 2017, and 21-22 August 2017 flood events. While Turkey Creek has gauges, none of the tributaries to Turkey Creek are

gauged, so there is uncertainty with respect to the contributions of each of these tributaries as they relate to the stage hydrographs at each site for the validation events. The StormWatch gauges evaluated as part of this validation are presented in Figure 5. In order to assess the gauges for validation, the stage hydrographs for each gauge for each event were overlaid against one another, and are presented in Figure 6, Figure 7, and Figure 8.

An evaluation of watershed geometry and the hydrologic modeling was also undertaken to assess whether the timing of the tributaries was likely to coincide with a peak on Turkey Creek, assuming an identical intensity and duration over the contributing watershed. A comparison of the approximate tributary length to that of the reach upstream of Turkey Creek was evaluated, as well as the flow hydrographs generated by the hydrologic modeling. A graphic of the approximate watershed boundary based upon the downstream end of the modeled reach is presented within the red boundary in Figure 9, while a comparison of a major ungauged tributary to the upstream boundary for the modeled reach is presented in Figure 10.

Based upon a comparison of the approximate watershed areas and the hydrologic response from the hydrologic modeling generated by the "Northeast Johnson County Watershed Study" in 2005 (Watershed Study), it was determined that it would not be possible to assume that the tributaries drained from their respective watersheds prior to the peak of the event on the mainstem of Turkey Creek. While the stage hydrographs from the respective gauges along Turkey Creek (i.e., TU03, TU04, and TU06) approximately coincide with one another in flow response shape and duration, it appears that the tributaries also very closely coincide with drainage response shape and duration relative to the Turkey Creek mainstem. An illustration of this is presented in Figure 11.

Due to the similarity in runoff response of the tributaries with that of mainstem Turkey Creek, the tributary inflow hydrographs could not be differentiated from the mainstem flows in the hydraulic modeling. If a differentiation in tributary versus mainstem hydrographs could have been identified, the identification of the mainstem hydrograph pulse could have been used to justify revising Manning's roughness values in the modeling to match the observed stage hydrographs at Turkey Creek StormWatch gauges at Johnson Drive (TU04) and I-35 (TU06). A rain-on-grid model has not been developed for the entirety of this watershed at this time, so a gridded precipitation simulation has not been performed to estimate the tributary flow contributions to improve the validation and/or calibration of the hydraulic model. Due to the highly developed nature of the entirety of the Turkey Creek watershed, the development of a detailed model would require significant time and cost. This effort is ongoing as part of the FEMA floodplain mapping update, however.

While it is not possible to calibrate the Manning's roughness values to closely approximate the observed stages at the stream gauges, it is possible to validate the results of the modeling with the observed stages. Figure 12, Figure 13, and Figure 14 provide illustrations of the computed water surface profile against the observed peak stage elevations according to the adopted datums. Note that for this analysis, the river centerline adopted for the Feasibility Study was used for the comparison of the computed flow profile to the stage measurements. Due to the inclusion of the turbulence components in the 2D analysis, slight variations in the water surface profile occur laterally within the channel. This variation in water surface elevation was previously separately computed as superelevation in one-dimensional hydraulic analyses according to Equation 2-31 in EM 1110-2-1601 but is now considered within the simulation capabilities of HEC-RAS. A comparison of the computed differences for the three events is presented in Table 5. Note that all simulations used the same mesh, bridge configurations, and roughness parameters.

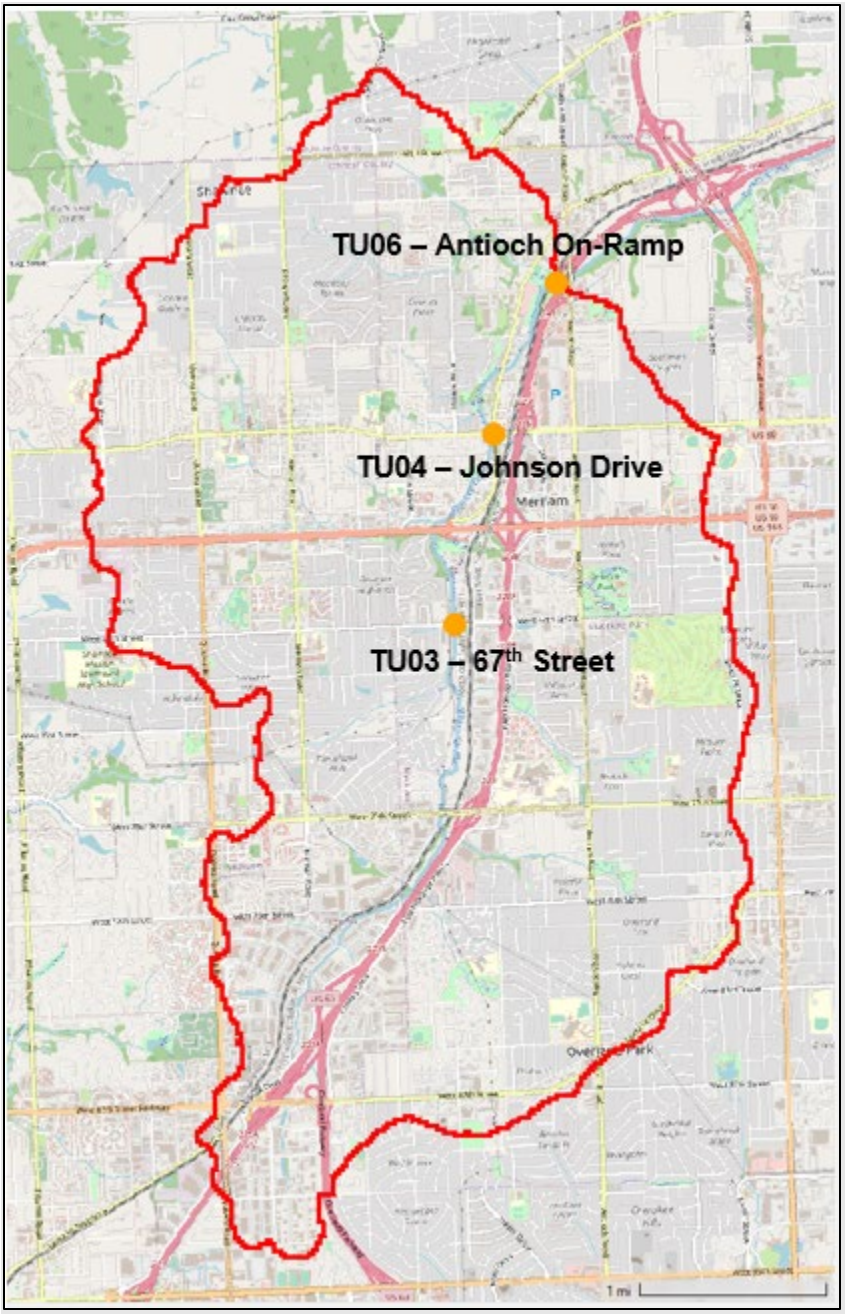

Figure 5. Orange dots indicate the locations of Stormwatch gauges TU03 – 67th Street; TU04 – Johnson Drive; and TU06 – Antioch On-Ramp within the Turkey Creek watershed upstream of I-35. The red perimeter indicates the approximate watershed extents of Turkey Creek upstream of where Turkey Creek passes under I-35 to the north. The modeled reach extends from I-35 at the downstream end to 67th Street at the upstream end. Flow direction is from south to north.

Table 5. Summary of computed differences between hydraulic model water surface and observed stage measurement at the respective 67th Street, Johnson Drive, and Antioch On-Ramp Stormwatch gauge locations.

Stormwatch ID	Location	26-27 July 2017 Elevation Delta	5-6 August 2017 Elevation Delta	21-22 August 2017 Elevation Delta
TU03*	67th Street*	0.00	0.00	0.00
TU04	Johnson Drive	2.69	4.12	2.63
TU06	Antioch On-Ramp	1.75	2.13	3.41

* This gauge was the upstream boundary condition location where a stage hydrograph was used. No difference in stage would be anticipated due to this.

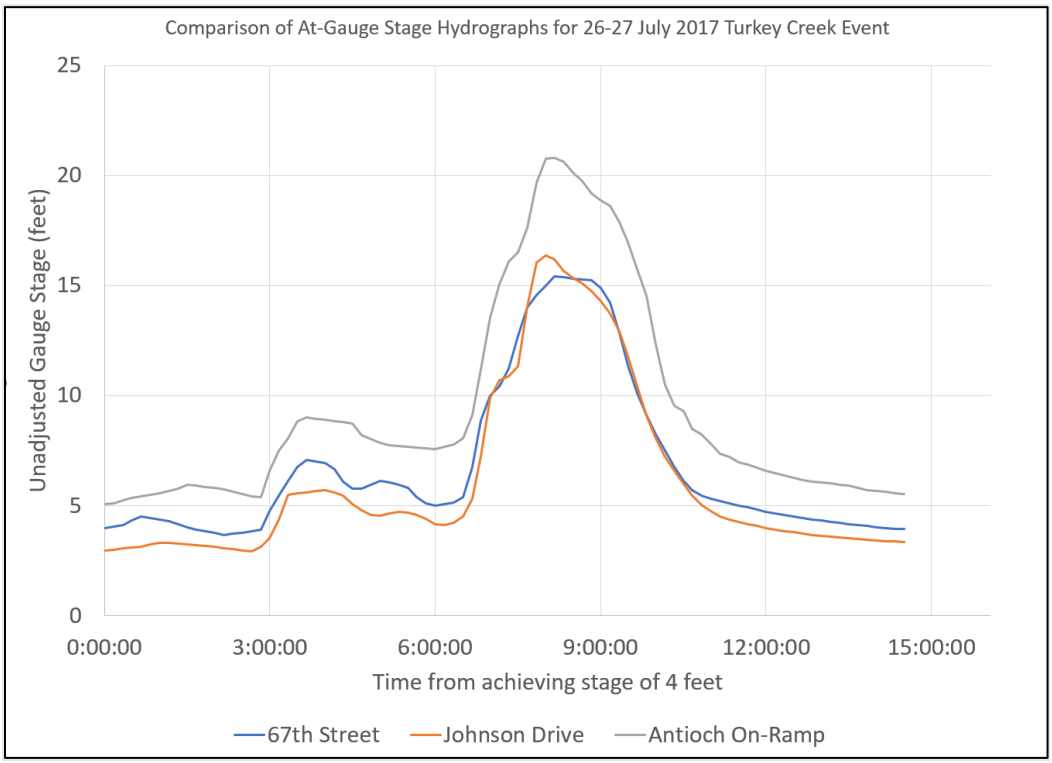

Figure 6. Stage hydrographs at 67th Street, Johnson Drive, and Antioch On-Ramp Stormwatch gauge locations for 26-27 July 2017 flow event.

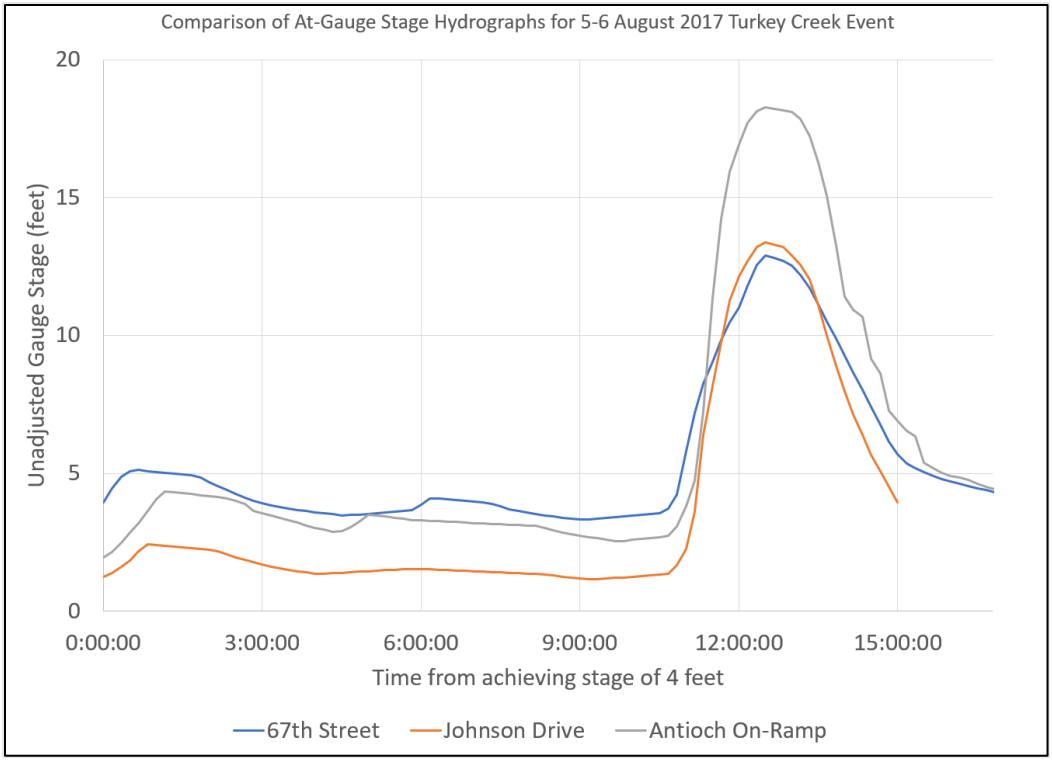

Figure 7. Stage hydrographs at 67th Street, Johnson Drive, and Antioch On-Ramp Stormwatch gauge locations for 5-6 August 2017 flow event.

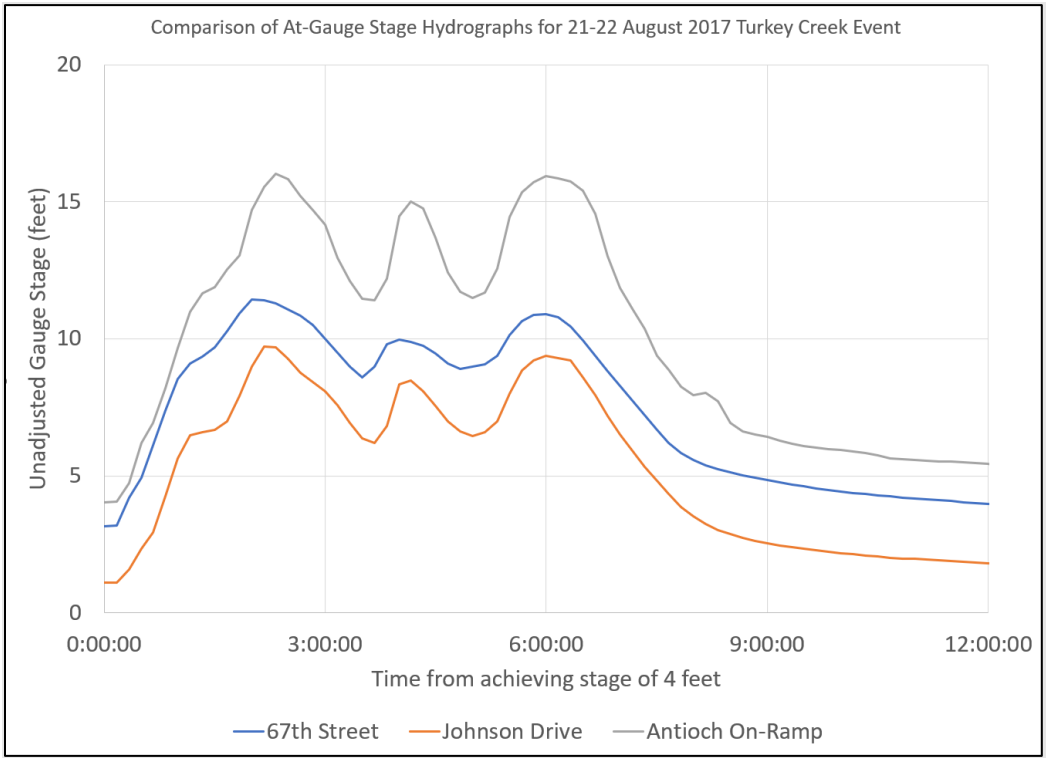

Figure 8. Stage hydrographs at 67th Street, Johnson Drive, and Antioch On-Ramp Stormwatch gauge locations for 21-22 August 2017 flow event.

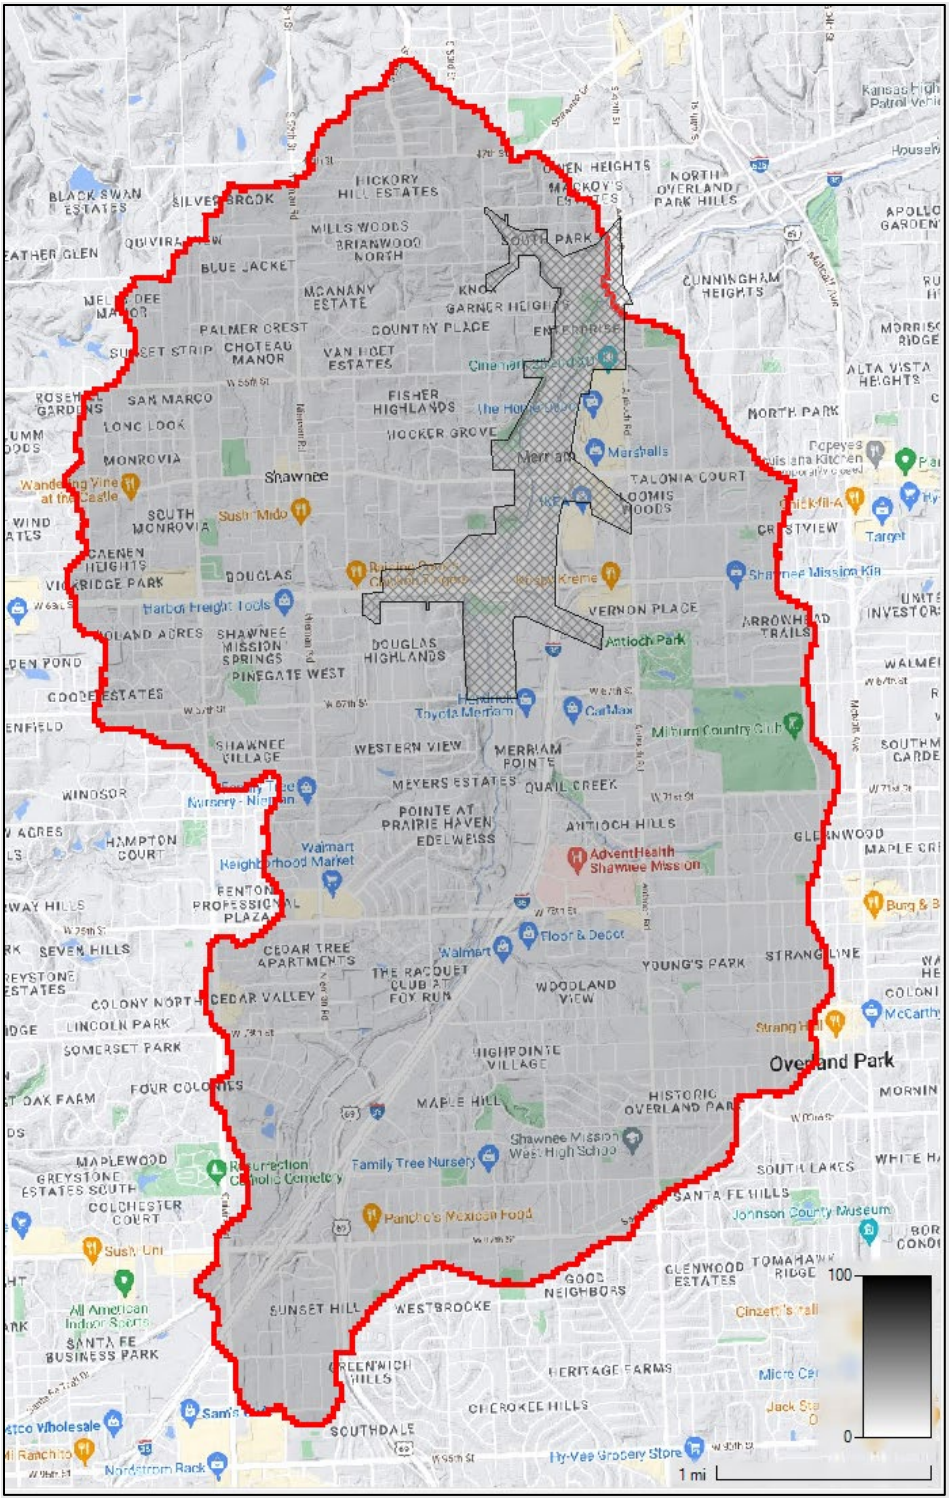

Figure 9. Approximate boundary for Turkey Creek watershed at Stormwatch gauge TU06 – Antioch On-Ramp at Turkey Creek.

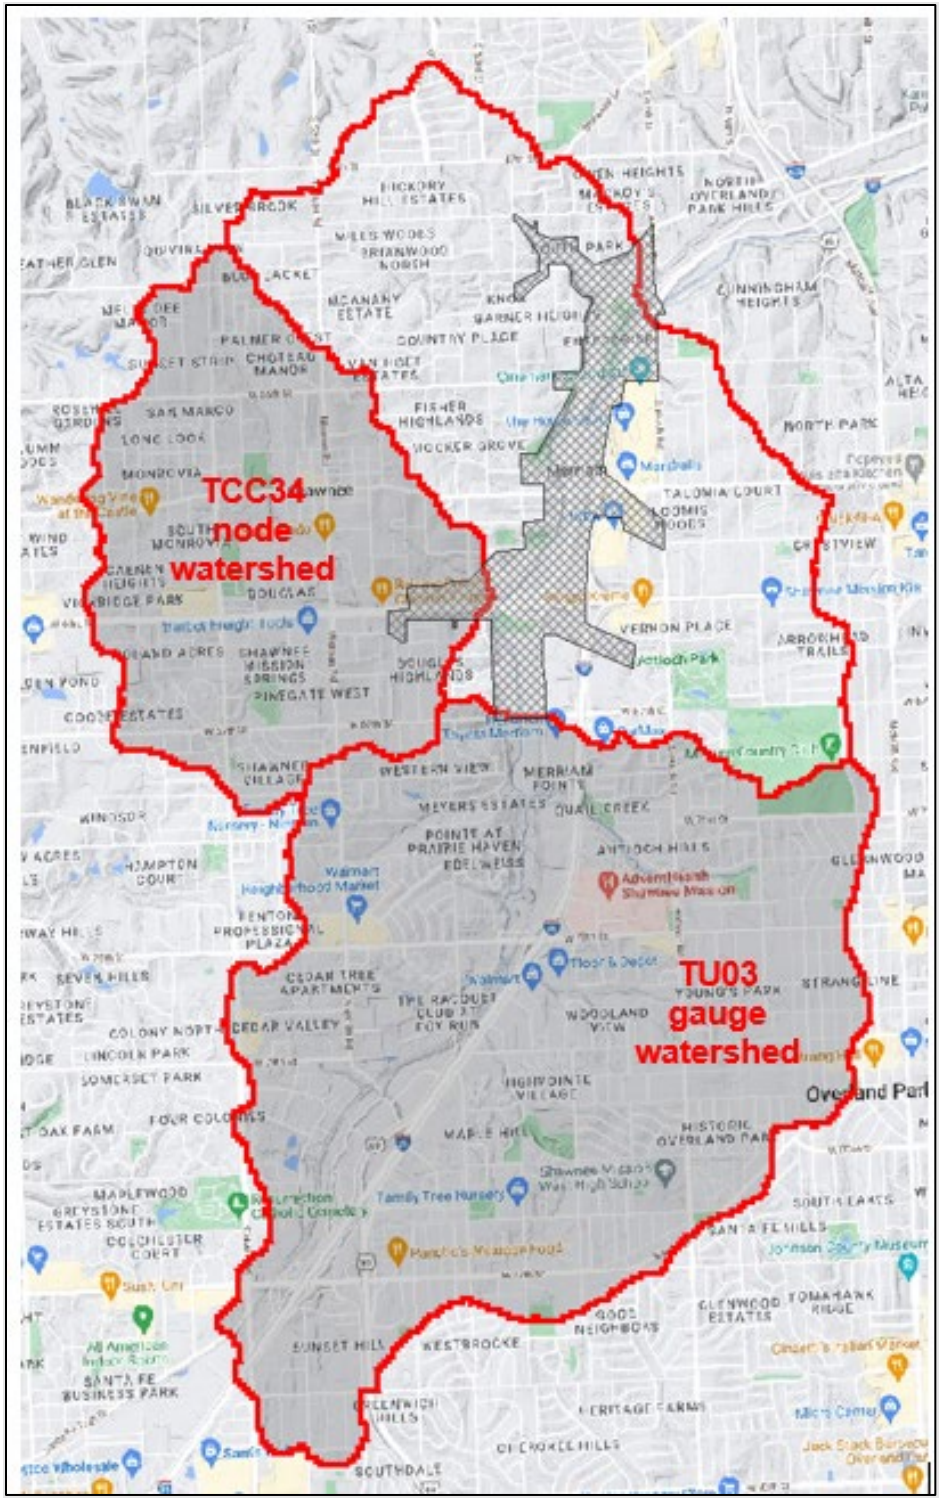

Figure 10. Approximate boundaries for Turkey Creek watershed at Stormwatch gauge TU03 – 67th Street at Turkey Creek and TCC34 node (i.e. the tributary which outlets adjacent to Shawnee Mission Parkway) from the hydrologic modeling. Larger boundary is extent of watershed boundary upstream of Stormwatch gauge TU03 – Antioch On-Ramp at Turkey Creek. Hatched area indicates simulated 2D mesh area.

E.4 Existing Conditions Comparison

Following the parameterization of the models, multiple methods of evaluation were identified using the more current two-dimensional modeling capabilities. The original one-dimensional Feasibility Study model was evaluated using a steady flow analysis only. The respective TP-40 and Atlas 14 24-hour precipitation accumulation values were evaluated over the entirety of the contributing watershed via the parameterized HEC-1 model, and only the peak discharges from the hydrologic model were entered at flow change locations within the HEC-RAS model as a steady flow model at cross-sections 2.065, 2.396, 2.813, 3.070, 3.665, 3.726, and 4.234.

For the two-dimensional analysis, two approaches were adopted for evaluation of the existing conditions. These were the use of a steady-unsteady simulation and the distribution of unsteady hydrographs within the Turkey Creek hydraulic model according to node location within the Feasibility Study hydrologic model.

E.4.1 Steady-Unsteady Simulation

The steady-unsteady simulation consists of using the same discharges adopted for the Feasibility Study over a 5-hour time interval to approximate a steady-state flow condition, like the steady-state modeling performed for the Feasibility Study. The flow change cross-section locations from the Feasibility Study were duplicated as boundary condition lines over the Turkey Creek channel, and constant value flow hydrographs were entered into the Unsteady Flow Data Editor within HEC-RAS to either add or subtract flow according to the differences computed from the flow change locations within the original steady-state model.

For the steady-unsteady flow simulation, two-dimensional boundary conditions are implemented as additive, in contrast to distinct value changes like they are in one-dimensional steady-flow HEC-RAS (at flow change locations). Therefore, the full upstream flow is entered, and then incremental positive or negative flow differences are entered at the respective downstream locations to add or subtract the necessary amount. A summary of the respective discharge increments, according to boundary condition location, are presented in Table 6.

Table 6. Summary of 1% and 0.5% AEP discharges from Feasibility Study and increments of discharge entered into two-dimensional existing conditions model at respective boundary condition locations.

Flow Change Cross Section (from Feasibility Study) (miles)	1% AEP Atlas 14 steady-state flow at flow change location (cfs)	Flow increment entered at respective 2D boundary condition (cfs)	0.5% AEP Atlas 14 steady-state flow at flow change location (cfs)	Flow increment entered at respective 2D boundary condition (cfs)
4.234 (Upstream)	10,047	10,047	11,248	11,248
3.726	10,381	334	11,629	381
3.665	16,855	6,474	18,610	6,981
3.07	17,691	836	19,657	1,047
2.813	17,348	-343	19,333	-324
2.396	16,613	-735	18,641	-692
2.065 (Downstream)	18,733	2,120	21,068	2,427

E.4.2 Distribution of Unsteady Hydrographs at Hydrologic Model Node Locations

For the second existing conditions flow profile evaluation, flow hydrographs from the hydrologic model were distributed within the hydraulic model at boundary condition lines within the model geometry according to their geographic node location within the hydrologic model used for the Feasibility Study. The computed flow hydrographs from the HEC-HMS model were scaled according to a ratio of the peak HEC-1 discharge divided by the the peak HEC-HMS discharge based upon the 1% and 0.5% AEP Atlas 14 discharges documented in the Feasibility Study.

Variations in the peak discharges were observed between the HEC-1 and HEC-HMS results, even though the HEC-1 modeled flows and geometry were directly imported into HEC-HMS. A spreadsheet adjustment of the HEC-HMS hydrographs was performed to exactly match the peak HEC-1 Atlas 14 discharges hydraulically simulated by the Feasibility Study. The HEC-HMS model was chosen to be carried forward for use for this evaluation due to the age of HEC-1 and the fact that the software is no longer updated or maintained by HEC for use. While the HEC-1 software is available, current software security measures in place within USACE makes its continued use challenging and HEC-HMS the preferred software tool.

For the unsteady flow simulation using the geographically-distributed unsteady flow hydrographs, HEC-HMS computed hydrographs were scaled according to the ratio of the peak discharges from the HEC-1 model to the peak discharge from the HEC-HMS model. Since HEC-HMS provides a timestep-by-timestep accounting of the flow contributions for each node, as well as at each combining node, the ratio of each subordinate node's discharge to the combining node discharge was used to scale the HEC-HMS computed discharges at each timestep according to the ratio of the peak HEC-1 discharge to peak HEC-HMS discharge via a spreadsheet. A sample computation for a single timestep flow adjustment at combining node TCC37 is presented below in Table 7.

An observed consequence of the insertion of unsteady flow hydrographs at the respective geographic node locations from the Feasibility Study hydrologic modeling into the existing conditions 2D hydraulic model is that the 2D mesh and digital raster terrain can intercept or generate storage of flows, or backwater, at the respective hydrologic model node locations.

Storage of flows or backwater may occur due to confinement or constriction of the stream due to a bridge or RCB. Ponding or interception may occur due to features in the terrain surface such as ponds or surface depressions, such as ditches or detention basins, which do not have drainage features, such as culverts or conduits, implemented within the hydraulic model. Due to the generalized parameterization which occurred with the hydrologic modeling of HEC-1 and HEC-HMS, detention and/or interception due to existing infrastructure and/or land surface modifications are not visualized and/or may not be accounted for in the same manner as they are in the hydraulic modeling.

Table 7. Sample adjustment computation for HEC-HMS individual timestep discharge to correspond with HEC-1 discharges evaluated by the Feasibility Study at combining node TCC37 (with subordinate contributing nodes TCR60, TC-T50, TC79, and TC67)

Node:	HEC-HMS Example Timestep Discharge (cfs):	Proportion of contributing node discharge to combining node TCC37 (percentage):	Arithmetic to scale contributing node from HEC-HMS (20,953 cfs) to correspond with Feasibility Study (HEC-1) peak discharge (17,691 cfs):	Scaled HEC-HMS discharge value used at individual timestep (cfs) in HEC-RAS:
TCR60	18.8	52.5%	35.8 x 17,691 / 20,953 x 52.5%	15.9
TC-T50	8.5	23.7%	35.8 x 17,691 / 20,953 x 23.7%	7.2
TC79	4.6	12.8%	35.8 x 17,691 / 20,953 x 12.8%	3.9
TC67	4.0	11.2%	35.8 x 17,691 / 20,953 x 11.2%	3.4
TCC37	35.8	100%	35.8 x 17,691 / 20,953 x 100%	30.2

A summary of the relationship between the Feasibility Study hydraulic model, and the hydrologic node corresponding with the flow change location is presented in Table 8. A description of the approximate node locations is presented in Table 9.

Table 8. Translation of Feasibility Study hydraulic model cross-sections to contributing hydrologic nodes

Feasibility Study Reach	Feasibility Cross-Section	Node – Contributing Nodes
TC-M80	4.234	TCC23 – none (upstream inflow boundary condition location)
TC-M80	3.726	TCC235 – TCR70*, TC94, TC-T71
TC-M80	3.665	TCC34 – TCR65*, TC-T59, TC66
TC-M80	3.07	TCC37 – TCR60*, TC-T50, TC79, TC64
TC-M80	2.813	TCC38 – TCR50*, TC-T40, TC57
TC-M80	2.396	TCC39 – TCR42*, TC48, TC41
TC-M80	2.065	TCC44 – TCC39*, TC-T30, TC19, TC38

* Locations on Turkey Creek included along routing reach. These nodes were not included in modeling as boundary condition locations.

A comparison of computed water surface profiles along the stream centerline adopted for the Feasibility Study is presented in Figure 15. It is noted that this profile comparison only represents the water surface elevations computed along the stream centerline adopted for the Feasibility Study. It does not represent the two-dimensional variability in water surface computed by this hydraulic analysis. The design water surface at the proposed levee/floodwall alignment for this project may be higher or lower than what is presented in this comparison due to two-dimensional effects, such as superelevation. A summary of the computed average, median, maximum, and minimum differences between the Feasibility Study and the current existing conditions models is presented in Table 9.

Table 9. Location descriptions of modeled hydrologic node locations

HEC-1/HEC-HMS Node	Boundary Condition Location Description
TCC23	Upstream boundary condition near XS 4.234. On Turkey Creek and immediately upstream of 67th Street Bridge
TC94	Approximately halfway between 67th Street and Shawnee Mission Parkway on the right bank of Turkey Creek
TC-T71	Right bank tributary to Turkey Creek immediately upstream of Shawnee Mission Parkway
TC-T59	Along tributary immediately east of Shawnee Mission Bridge over Turkey Creek.
TC66	Between Mastin Street and the left bank tributary to Turkey Creek immediately downstream of Shawnee Mission Parkway
TC-T50 & TC64	Along right bank of Turkey Creek approximately 250 feet upstream of Johnson Drive Bridge over Turkey Creek
TC79	Along left bank of Turkey Creek approximately 410 feet upstream of Johnson Drive Bridge over Turkey Creek
TC-T40	Along left bank tributary which drains into Turkey Creek near the Merriam Marketplace Pedestrian Bridge. Approximately 450 feet west of top of left bank.
TC57	Along right bank of Turkey Creek approximately 150 feet downstream of the Merriam Marketplace Pedestrian Bridge.
TC48	Along right bank of Turkey Creek. East of I-35 and approximately straight east of W 55th Street.
TC41	Along left bank of Turkey Creek. Approximately 90 feet upstream of the DS Bus Lines Bridge.
TC-T30	Along left bank of Turkey Creek. Along left bank tributary to Turkey Creek near Waterfall Park. Approximately 190 feet east of Merriam Drive.
TC19	Along left bank of Turkey Creek. Along left bank tributary to Turkey Creek near Waterfall Park. Approximately 70 feet east of Merriam Drive and 100 feet west of TC-T30.
TC38	Along left bank of Turkey Creek. Approximately 500 feet east-southeast of the intersection of W 53rd Street and Merriam Drive

Table 10. Computed statistics for differences between 1% AEP Feasibility Study Pre-Project Profile and respective existing conditions profiles

Scenario	Average Difference (ft)	Median Difference Value (ft)	Maximum Difference (ft)	Minimum Difference (ft)
1% AEP Atlas 14 Steady-Unsteady	0.67	0.82	3.89	-4.42
1% AEP Atlas 14 w/ flow hydrographs	0.41	0.65	5.43	-2.96

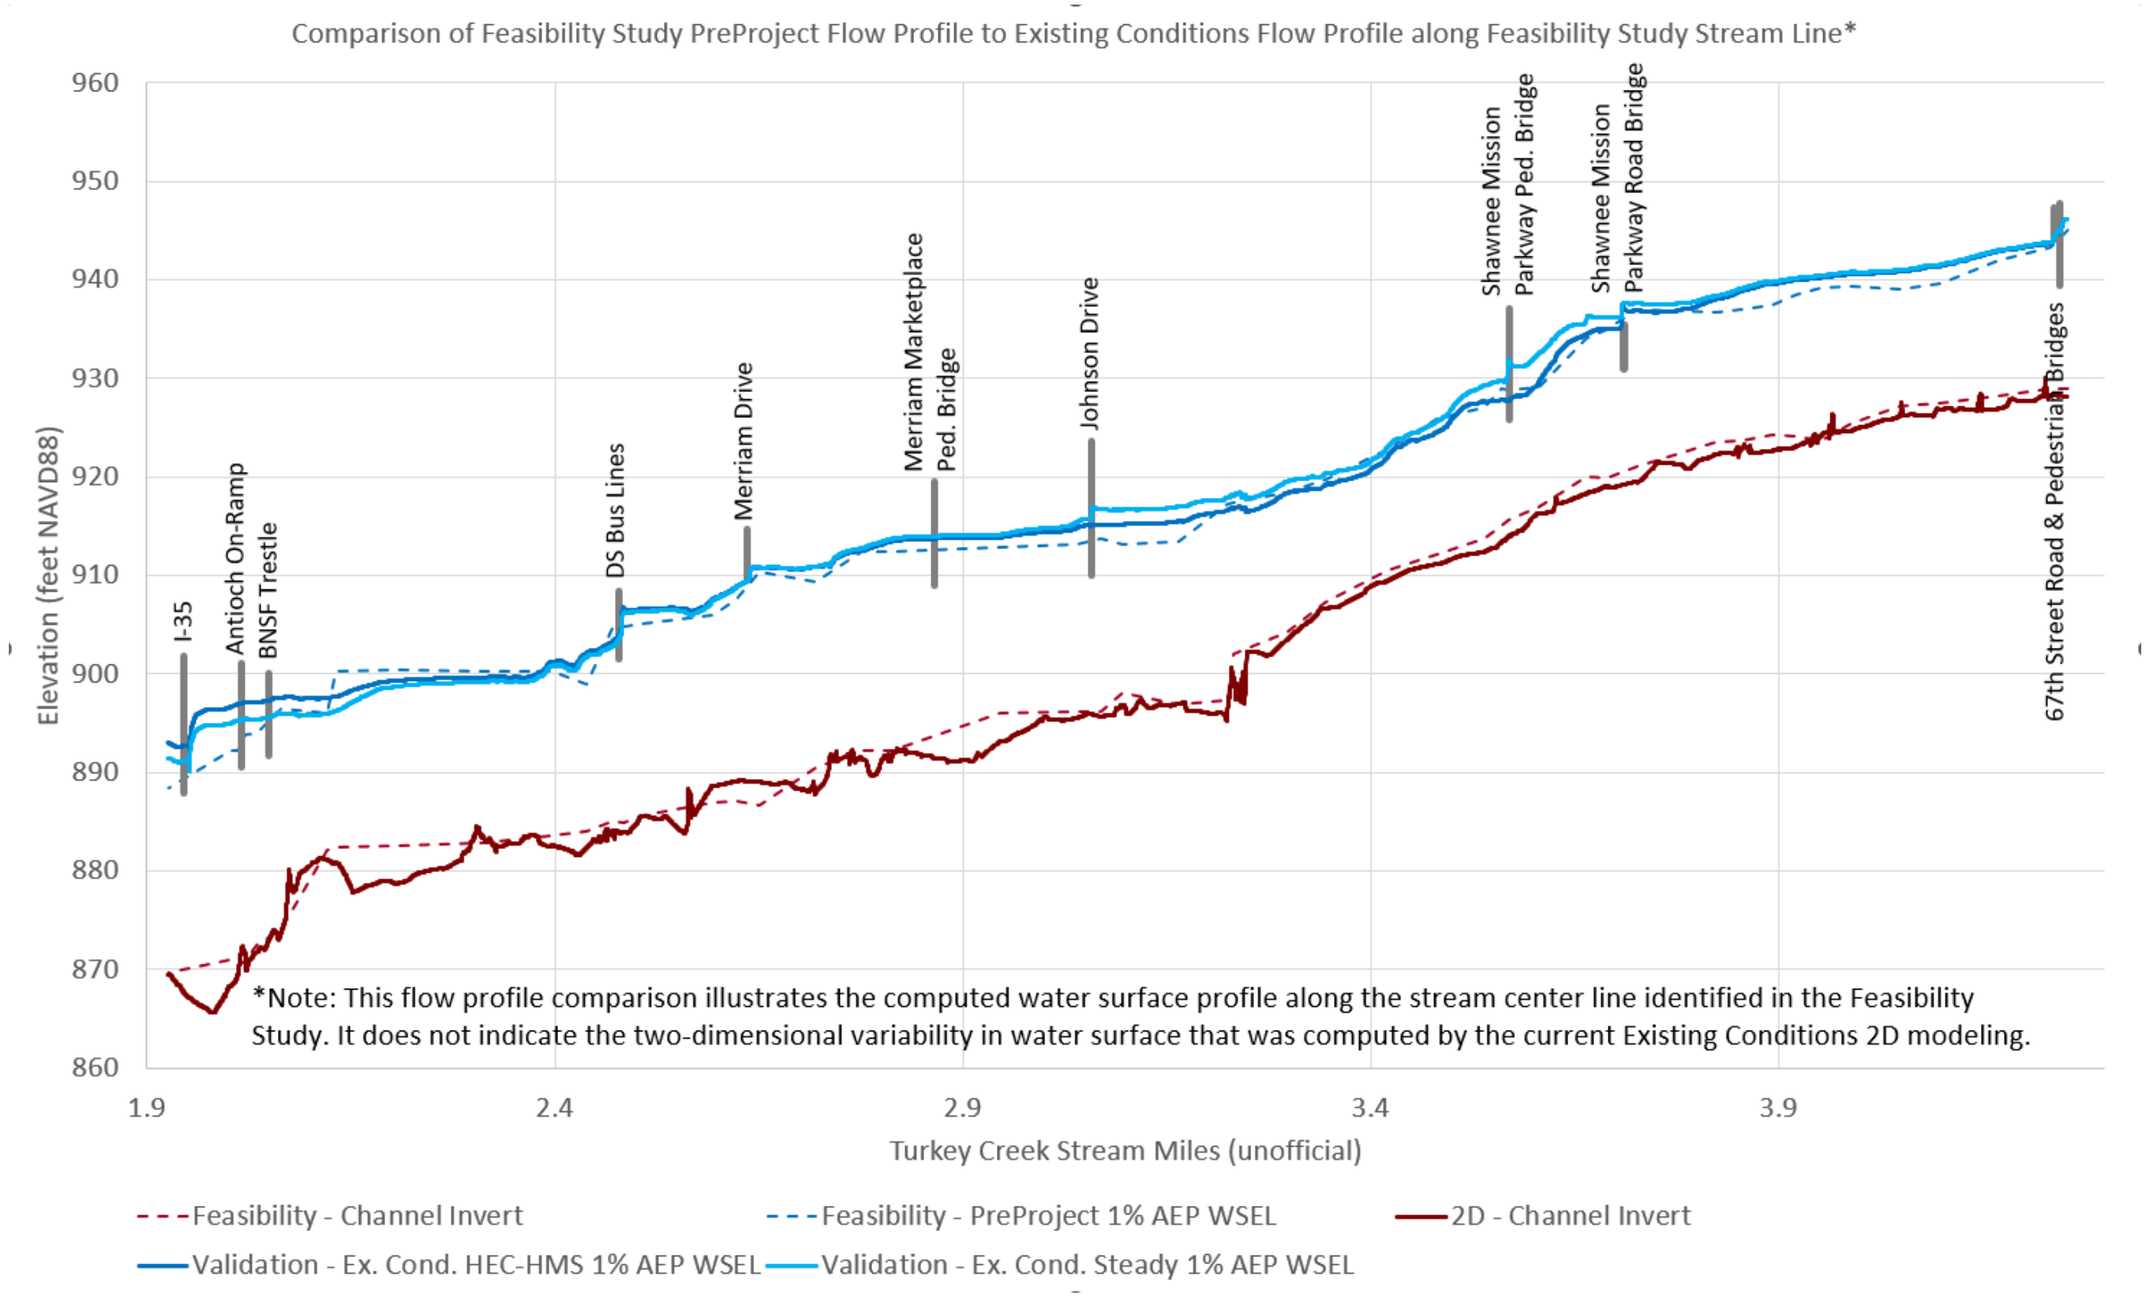

Figure 15. Comparison of pre-project or existing conditions 1% AEP, Atlas 14-based water surface profiles from the Feasibility Study (blue dashed line), and the current analysis (dark blue is the flow hydrograph analysis and light blue is the steady flow hydrograph analysis). The channel invert along the stream centerline is indicated by the brown lines (Feasibility Study is dashed; current analysis is solid).

Re: Preliminary Review, Upper Turkey Creek streambank protection, Merriam – Johnson County

We have reviewed the request for comment on a potential project that would be subject to review in accordance with 36 CFR Part 800. In reviews of this nature, the State Historic Preservation Office (SHPO) determines whether a federally funded, licensed, or permitted project will adversely affect properties that are listed or determined eligible for listing in the National Register of Historic Places. According to the submission, the proposed project will include the acquisition and potential demolition of residential structures of various ages. Without knowing which structures will be demolished, we are unable to comment on the architectural impact. However, we have reviewed the project for archeological potential and have no concerns with this aspect of it.

We expect to receive additional information regarding the structures to be demolished as they become available. Any work that does not include demolition of structures may proceed. Please submit any comments or questions regarding this comment to Lauren Jones at 785-272-8681, ext. 214 or lauren.jones@ks.gov.

Sincerely,

Patrick Zollner
Director, Cultural Resources Division
Deputy State Historic Preservation Officer

DEPARTMENT OF THE ARMY
U.S. ARMY CORPS OF ENGINEERS, KANSAS CITY DISTRICT
601 E. 12TH STREET, 635 FEDERAL BLDG
KANSAS CITY, MO 64106-2824

December 16, 2022

Mr. Patrick Zolner
Acting State Historic Preservation Officer
Kansas Historical Society
6425 SW 6th Avenue
Topeka, KS 6615-1099

Dear Mr. Zolner:

The U.S. Corps of Engineers, Kansas City District (USACE) is planning a feasibility study for flood risk management actions in a short stretch of Upper Turkey Creek in the city of Merriam, Johnson County, Kansas. The project area is a 1.25-mile section of the creek near downtown Merriam in Section 12 T12S R24E (Figure 1). This letter continues consultation for the project under Section 106 of the National Historic Preservation Act that was begun in May 2012, Kansas R&C number 12-OS-134. The letter from your office is attached for your reference in Appendix A. Cultural resources figures and maps are in Appendix B and the project details are in Appendix C.

Project Description

The Recommended Plan is a levee and floodwall along Turkey Creek in the city of Merriam. The features extend from Shawnee Mission Parkway to Merriam Drive, a stretch that includes Merriam's main downtown reach, as well as a commercial and industrial area just south of Johnson Drive. Most of the protected area is on the right bank of Turkey Creek (Figure 2). In the feasibility plan, four properties have been identified for removal (Appendix C).

Background

An archaeological background review of the project area was conducted including a search of the Kansas Archaeological Viewer (online); Kansas Historic Resources Inventory (KHRI, online) the NRCS Web Soil Survey (online); the online National Register of Historic Places (NRHP); LiDAR imagery; historic plat and topographic maps; General Land Office (GLO) records, and in-house USACE records.

As part of the 2012 cultural resources review for the previous feasibility study of the project, USACE archeologist David Cain performed a background review of the available resources and a field reconnaissance survey of the proposed project area. The crossing of the road connecting Ft. Leavenworth and Ft. Scott is depicted crossing Turkey Creek just north of Shawnee Mission Parkway (Figure 3). The trail is also noted in the project area with a marker sign. No LiDAR indications of the trail are present in or near the project area (Figure 4). Field investigations by Cain (2012) showed that the soils in the area are severely disturbed by urban development and historic properties of

an archaeological nature are very unlikely in the channel, a conclusion with which your office concurred in 2012.

No other archeological surveys have been performed since Cain's and no archeological sites have been recorded near the project area since his review. Cain was not able to access the KHRI database. As part of the current study, the KHRI online database was reviewed for architectural resources within or near the project area. Several resources are recorded within a few blocks of the study area (Figure 5), including the RW Hocker Subdivision spec house listed on the National Register of Historic Places (NRHP).

Two architectural resources are recorded directly adjacent to the Turkey Creek project area (Figure 5). The closer, southern building is Merriam School at 5820 Merriam Drive (KHRI 091-2463). The oldest part of the building was built in 1872 and was used as a school until 1911. Since then, it has been modified and used for retail space. The building is in good condition but has not been assessed for NRHP eligibility. It is only 45 m from Turkey Creek but there are no plans to affect it as part of this project. The second building is the subsequent Merriam school, built in 1911, located at 5701 Merriam Drive (KHRI 091-3781). The building served as a school until 1969 and served several other purposes including as the Merriam Community Center from 1990. The building is now gone, having been demolished at some time in 2021, per Google Earth historical images.

Five properties indicated for acquisition and removal in the feasibility plan (Appendix C) are:

- Property JP35000000-0009: a general office building (5568 Merriam Dr.). Built 1963.
- Property JF241212-3005: a warehouse structure (5726 Merriam Dr.). Built 1986.
- Property JF241212-3006: a warehouse/office structure (5816 Merriam Dr #A). Built 1962.
- Property JF84000009-0001A: a shed (5836 Merriam Dr). Possibly built 1986.
- Property JP28000033-0024D: a residence (9675 W. 61st St.). Built 1986.

The first three buildings appear to be concrete block commercial structures of various ages. The shed appears to be corrugated metal. Because it is very likely these properties will change during the design phase of the project, they will be surveyed and uploaded to KHRI at that time to aid their evaluation for NRHP eligibility.

Further consultation with your office will take place during the design phase of this project when specific locations and actions are determined. The project locations, such as the levee and detention basin footprints, will be reviewed again at that time. If your office has information on any cultural resource that may be affected by the proposed project of which we may be unaware, we would take such information into account for our final determination of effect.

Thank you for your consideration in this matter. If you have any questions or have need of further information please contact Gina Powell, USACE Kansas City Archeologist, at Gina.S.Powell@usace.army.mil or at (816) 389-2320.

Sincerely,

Dr. Gina S. Powell, Archeologist

RE: Flood Risk Management Project
Upper Turkey Creek Basin
Johnson County

Dear Mr. Meade:

In accordance with 36 CFR 800, the Kansas State Historic Preservation Office has reviewed a report entitled *Archeological Survey of Upper Turkey Creek Basin, Flood Risk Management Project Johnson County, Kansas*, by David I. Cain. We find the report to be acceptable and concur with the recommendation that the project as proposed should have no effect on properties listed in the National Register of Historic Places or otherwise identified in our files. This office has no objection to implementation of the flood risk management project.

This information is provided at your request to assist you in identifying historic properties, as specified in 36 CFR 800 for Section 106 consultation procedures. If you have questions or need additional information regarding these comments, please contact Tim Weston at 785-272-8681 (ext. 214) or Kim Gant at 785-272-8681 (ext.225).

Sincerely,

Jennie Chinn, Executive Director and
State Historic Preservation Officer

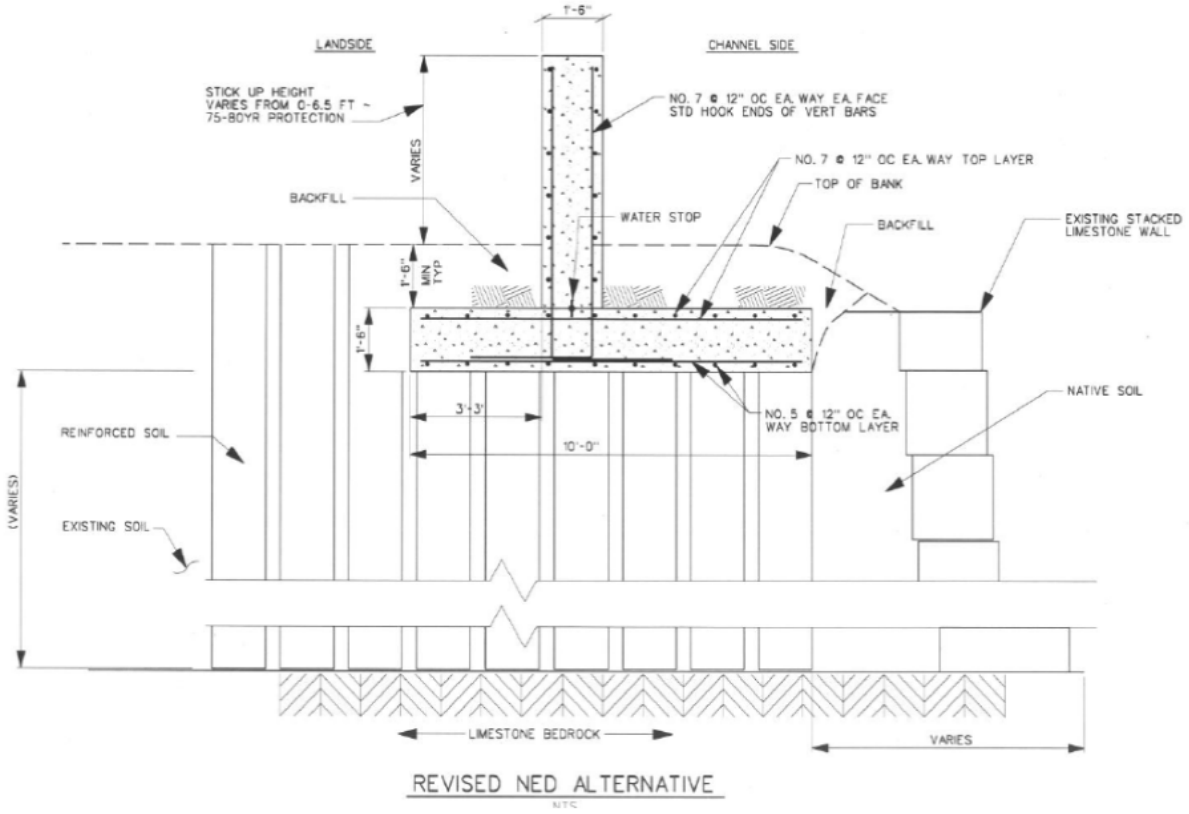
APPENDIX G
Typical Floodwall



Typical Floodwall Detail (FS)

APPENDIX H
Cost Estimate

APPENDIX H – COST ESTIMATE

COST ESTIMATE

H.1 General

A reprised feasibility level estimate has been developed and is provided under separate cover upon request. The scope of work includes the recommended alternative to construct a flood risk management project in the City of Merriam in Johnson County, Kansas along Turkey Creek. The recommended plan is a levee and floodwall plan in the City of Merriam. The current working estimate is not considered “For Official Use Only.”

H.2 Contract Acquisition

The acquisition method is assumed to be full and open IFB.

H.3 Estimated Project Duration

The estimated duration for this contract is 40 months. It is assumed the construction will begin in February 2027. The midpoint of construction is assumed to be in December 2028.

H.4 Basis of Estimate

The basis of the estimate is the final feasibility study dated December 2014.

H.5 Estimate Preparation

This cost estimate was prepared using the Micro Computer Aided Cost Engineering System (MCACES) Second Generation (MII), version 4.4.2. The following supporting databases were used in the preparation of the cost Estimate:

H.5.1 Cost Book

CB22EN (2022 MII English Cost Book); each unit cost was analyzed and adjusted to reflect current costs.

H.5.2 Labor Rates

This estimate uses a prevailing wage labor rates for Jackson County, MO. The Davis Bacon Wages from decision KS20210026 dated 1 June 202022 were used for

preparing the estimate.

H.5.3 Equipment Rates

This estimate is based on the latest available/supported MCACES MII equipment rate database (EP20R05), which has been updated for the estimate to more accurately represent current prices.

H.5.4 Contractors/Subcontractors

The estimate assumes the majority of the work will be performed by the prime but some subcontracting will be needed by the prime to execute the project.

A surety bond rate was assumed for the Prime Contractor. The bond rate is calculated by the MCACES MII software.

The following markups were applied to the Prime Contractor's work: Job Office Overhead, Home Office Overhead, Profit, Bond, Contingency. Currently a contingency of 44% is being applied until further design detail is provided. Other specific percentages are retained in MII.

The following markups were applied to any subcontracting work: General Overhead and Profit.

An equipment adjustment factor has been applied to the 2020 Equipment prices to update the equipment to current pricing. An equipment adjustment factor has been applied to all equipment items. The adjustment factor has been derived by assuming and escalation factor of 2.0% per year.

A material adjustment factor of 15.03% has been applied to the 2022 Cost Book Material prices to update the materials to current pricing. The adjustment factor has been derived from the Engineering News Record index for construction material.

A sub bid adjustment factor of 4.42% has been applied to the 2022 Cost Book Sub Bid prices to update the sub bids to current pricing. The adjustment factor has been derived from the Engineering News Record index for construction cost.

H.6 Project Owner Markups

The owner also has markups on the project level that are applied after contractor markups. These markups are include: escalation and supervisory and administration. below.

Escalation = 17.5%

Construction Contingency = Included in design contingency.

S&A = 10%

H.7 Cost Drivers and Risks

Updating the cost and schedule risk analysis (CSRA) after each design submittal will help better define cost and schedule risks and provide confidence levels in being able to complete the project at various funding amounts. Below are high level risks.

- Bridge headwall modification and bridge scour not adequately scoped in feasibility
- Flood Wall Lengths
- Ground Improvement - AGP Depth and Width
- Real Estate Limits
- Relocations
- Flood Wall Lengths
- Scope Uncertainty
- Market Conditions and Competition

H.8 Market Conditions and Competition

A large factor in the total project cost will be the number of bids received as open competition has a significant impact on receiving a fair and reasonable price. Historical data shows a small labor pool and the lack of labor could affect cost and schedule.

H.9 Scope Uncertainty

There are many unknowns in the current scope that could impact the total project cost. The estimate will change throughout design as the scope becomes better defined. Below are a few of the unknowns.

- Fill Material sourcing is not final
- Secant Wall or AGP T Wall designs are not final.
- Unknown condition of limestone retaining wall.
- Possible new bridge
- Long term city plans

APPENDIX H – SURVEY REPORT

This page was intentionally left blank for duplex printing.

STOCKWELL

Topographic Survey, GPR and Drafting of Upper Turkey Creek, Merriam, Kansas

Performed by Stockwell Engineers Inc.
for the U.S. Army Corps of Engineers, Kansas City District
Under Contract No. W912DQ-19-D1006
Delivery Order No. W912DQ23F1001

Coordination of the work started prior to crews being on site between Joe Whitlock and Brett Kennedy with Stockwell, Greg Fox and David Kuxhausen of Woolpert and Katrina Marx, John Calcara, Courtney Forsythe and Brian Vanbockern of the USACE, Kansas City District.

This task order involves project setup, checking of existing control, topographic data collection, GPR investigation and drafting of collected survey data for use in upcoming design projects along the Upper Turkey Creek corridor in Merriam, Kansas. The field work for this project was completed from February to April of 2023. Temperatures ranged from 25˚ to 75˚ F.

Stockwell Engineers Survey Crews mobilized to the site in Merriam, Kansas on the 21st of February 2022. Our crews set a base point (CP-1) towards the south end of the site near “Skate City”. We performed two separate OPUS solutions on the point to obtain an accurate position. We then completed checks on NGS points R328 and Shawnee2. During these checks we determined that horizontally the position was accurate but vertically it was about 0.3’ difference. We then adjusted to NGS point R328 to establish the elevation of CP-1.

Once the position was established Stockwell’s crews checked existing control established by BHC for the Merriam Drive project for the City of Merriam in drawing page 4 of 94 in the vicinity of the Upper Turkey Creek survey and determined that it was within 0.1’ horizontally and vertically which we felt was acceptable. Our crews then went through the site and set control points every 800’ to 1000’ to use while surveying with robotic total stations. After the control was set and marked, we completed a level loop across the control using a Trimble DiNI level.

During the first week on site February 20 thru February 24, Bill Welbaum with Woolpert, Inc. was onsite doing GPR work on the 4 sites in question. During that time our surveys crews would meet with Bill a couple of times each day to pick up all marked out areas before they were lost due to traffic or work activities that were going on in the area. *(See attached report from Woolpert describing their findings and showing pictures of field conditions.)*

Upon completion of the Level Loop our crews began performing the topographic survey for the site utilizing both GNSS and Robotic Total Stations using three to four crew members at all times.

STOCKWELL

During this week we completed the topographic survey of the creek bed and the intersection around Mastin and Shawnee Mission Parkway north to the north end of the Skate City property.

Stockwell's crews continued to work on the topographic survey for the next 6 weeks. During that time, our crews continued utilizing both GNSS and Robotic Total Stations along with a Trimble SX10 Terrestrial Scanner to scan the overhead power and communication lines that cross the project.

Along with the ground survey our crews measured the inverts of all manholes, storm inlets and boxes and utility vaults and manholes. Manhole information sheets were created and provided to Woolpert Staff to add all necessary information to the topographic survey drawing.

Throughout this Delivery Order there were only a few issues. One minor one was that the property owner at 5920 Merriam Drive did not receive our letter informing them that there was going to be a survey going on around their property. When our crew was working on site they were told to leave and stay off the property. Upon this interaction our crews left the site and contacted Katrina Marx with the USACE, Kansas City District to let her know what the situation was. Katrina then talked to some people at the City of Merriam, and they stopped over at the property, talked with the property owner and explained what we were doing and they then allowed us back on the property to complete the topographic survey. Stockwell's Crews arrived the next morning and completed the survey on that property.

The biggest issue throughout the topographic survey was getting the underground utility locates completed. Stockwell Engineers, Inc. called in three different locate tickets with little to in most cases no locates being marked in the field. Joe Whitlock called all utility companies that were contacted as part of the Kansas State One Call System and spoke with representatives of the companies trying to get their locating contractor to mark the lines in the field. Through all of this Joe Whitlock spoke to the different utility companies and to USIC, LLC who was the utility locating contractor that wasn't performing their work. After quite a bit of back and forth they assured me that all of this would be located, and they would let Joe Whitlock know when the work was complete. Mr. Whitlock was never contacted by USIC, he traveled to Merriam, KS the first week in June to pick up a couple of building corners and finished floor elevations, while on site he walked the site and didn't find any new markings that were marked as part of the Upper Turkey Creek Topographic Survey.

STOCKWELL

Throughout the duration of the survey of Upper Turkey Creek Stockwell Engineers has been in contact with Katrina Marx and other staff from USACE Kansas City District. We had the kickoff meeting, CADD progress and review meetings and numerous phone calls and emails to discuss the progress and issues that have been noticed.

Stockwell Survey Crews:
The daily field data collection was overseen by Joe Whitlock.

Stockwell Crew Members:
Logan Hanzel
Dan Feucht
Jared Reed
Trenton Olson

Stockwell sub-contracted the GPR and Drafting portion of the work to Woolpert, Inc., which is Stockwell's team member on the IDIQ for this contract.

Equipment utilized by Stockwell Engineers Inc. for this survey included:

- ♦Trimble TSC7 Data Collectors
- ♦Trimble TSC3 Data Collectors
- ♦Trimble R10-2 GNSS Receivers
- ♦Trimble R12i GNSS Receivers
- ♦Trimble R8 Model 3 GNSS Receivers
- ♦Trimble R6 Model 3 GNSS Receiver
- ♦Trimble S6 Robotic Total Station
- ♦Trimble SX10 Scanning Total Station
- ♦Trimble Business Center Software Version 5.2.

The horizontal datum for the project is Kansas State Plane North (1501), NAD83 in U.S. Survey Feet. The vertical datum used was NAVD88, (Geoid 18) also with all elevations in U.S. Survey Feet.

All survey field notes were kept in a field book and transferred to an electronic daily notes' spreadsheet. Photographs were taken when needed to assist in answering questions that come up. Manhole Information Sheets were also used to better describe the interior of the manholes giving depths to the inverts, size and materials of pipes, and the present use. These sheets were filled out in the field and have been since scanned and saved for possible future use.

Field Report

Upper Turkey Creek **Kansas City, KS** **Date Written:** ***July 27, 2023***	
Order Number : 10017662	**Field Report Number : 10017662**

Date of Visit	Time of Visit	Weather	Present at Site
February 20, 2023	7:30am	Clear	Bill Welbaum

Introduction:

Ground Penetrating Radar (GPR) was deployed to investigate the potential existence of abandoned underground fuel / storage tanks at four (4) different locations withing the project area.

Objectives:

Identify the potential existence of abandoned underground fuel / storage tanks.

Methodology:

Woolpert deployed a one-man field crew outfitted with the Sensors and Software LMX200 Ground Penetrating Radar using ultra-wideband 250 MHz frequency. The GPR unit was used to assess the possible existence of buried structures. Any identified abnormalities in the soils were painted on the ground as part of that survey. Those marks were then surveyed by Stockwell Engineers. GPR data was reviewed in real time. The LMX200 unit deployed did not store raw data files.

Survey Results:

Any soil inconsistencies or areas that the GPR indicated that soil abnormalities were outlined with paint on the surface, photographed, and reviewed with the survey crew that was on-site.

Data Analysis and Interpretation:

The most common feature seen in GPR data is hyperbolic reflections. These hyperbolas are produced by subsurface objects or interfaces that reflect the radar waves back to the antenna. The shape and position of the hyperbolas provide information about the depth and geometry of subsurface structures. When hyperbolic reflections were seen in the GPR display, paint marks were placed to outline the data findings in real-time.

EXECUTIVE SUMMARY

Project Description

The Upper Turkey Creek Flood Risk Management (FRM) project is located in the City of Merriam, in Johnson County, Kansas. Turkey Creek is a right-bank tributary of the Lower Kansas River. The project consists of levee, floodwall, drainage structure, bridge replacement, and recreation features. The project length is approximately 1.5 miles on both left and right banks of the creek. Levee and floodwall features have a maximum height of approximately 10-14 feet. The non-federal sponsor for this project is the City of Merriam, Kansas. Johnson County, Kansas, contributes to the city's cost share and is involved in the design phase. Part of the Turkey Creek channel in the study area is operated and maintained by the Merriam Drainage District (MDD) under a state charter that provides MDD authority independent of the City of Merriam or Johnson County. MDD may be responsible for operation and maintenance of this project in the future. The project is currently at 35% design, at which point a risk assessment for the purposes of risk-informed design was conducted with the Project Delivery Team, facilitated by the Levee Safety Center.

Risk Characterization

The incremental life safety and economic risk of the Upper Turkey Creek FRM project, for both the left and right bank levee systems, is estimated to be driven by capacity exceedance of the levees and floodwalls resulting in an overtopping breach potential failure mode. The proposed project is in the design phase and the final configuration is still being developed, however, prior-to-overtopping potential failure modes were identified with the current plan and found to be tolerable or sufficiently excluded through the proposed design. Due to the location of the project within an urban area, there is extensive infrastructure along and through the proposed alignment including thousands of feet of sanitary sewer up to 42" in diameter. The team identified a risk associated with the plan to minimize relocations of the sanitary sewer in certain cases and found the risk to be more than one order of magnitude lower than overtopping breach risk. While some cases, such as existing sewer junctions (e.g., "manholes") within the levee footprint and their associated pipes, will need to be relocated, other cases of existing sewer crossing the channel or along the proposed levee toe were found to have low risk and are likely able to remain in place. The risk of internal migration of embankment and foundation material into these pipes is estimated to be low due to the short duration of flood events and the unlikely condition of major defects in the pipes, provided they are inspected prior to approving the pipes to remain in place. The other identified risk of the project is levee global instability if steady-state conditions were to develop, creating high landside seepage pressures, and no mitigating features are included in the design. The team estimated this risk to be low due to the short duration of the flood event making steady-state conditions unlikely and the low likelihood that an instability would progress in a sufficient amount of time and extent to result in a breach of the levee. Intervention for all potential failure modes is likely to be unsuccessful due to the nature of the fast-rising flood event with little warning or preparation time and intense rainfall conditions during the time to take action. Both incremental life loss and incremental economic damages are expected to be low. The short duration of the flood event results in low peak flows and total volumes through potential breach openings. The non-breach risk quickly approaches the total risk of the project for overtopping scenarios due to the small leveed areas filling quickly from overtopping flows. Economic damages are largely driven by damages to the commercial area located within the right bank system. Life safety risk is

primarily present in the residential area in the left bank area at night and in the commercial area on the right bank during the day.

The societal incremental life safety risk estimates with and without intervention are portrayed in Figure ES-1 and summarized in Table ES-1.

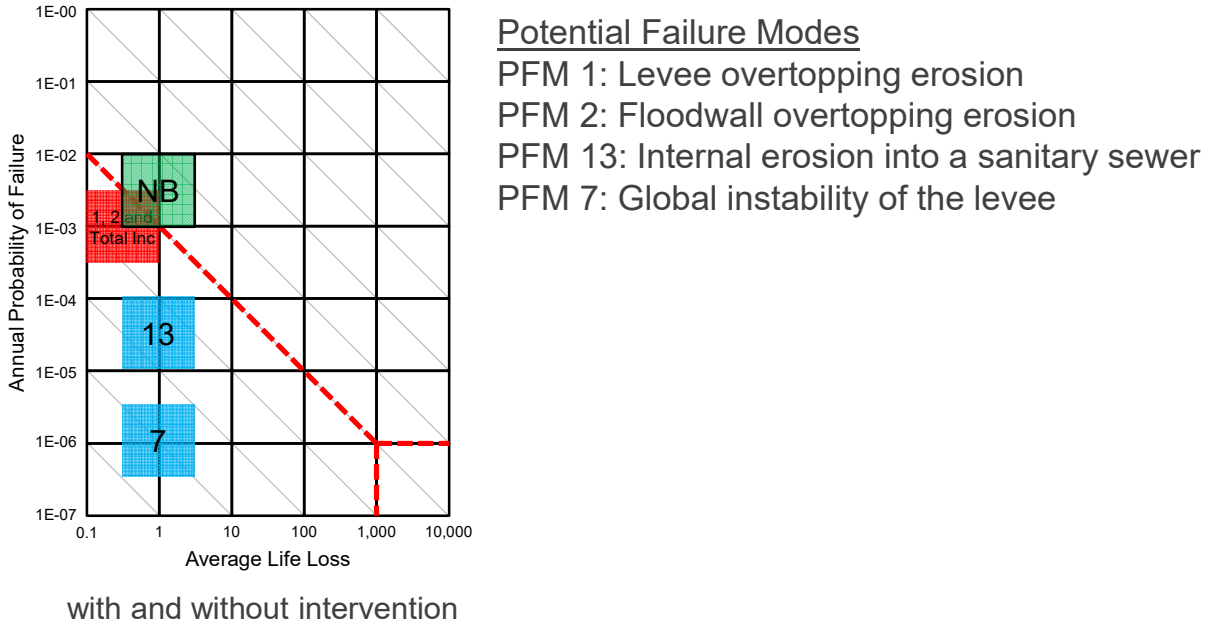

Figure ES-1 Societal Incremental Life Safety Risk Matrix

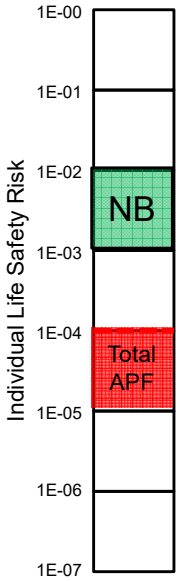
Table ES-1.
Societal incremental life safety risk summary (with and without intervention).

Potential Failure Mode	Annual Probability of Failure, APF (failures/year)	Average Incremental Life Loss, $\bar{N}$ (lives/failure)	Average Annual Incremental Life Loss, AALL (lives/year)		
PFM 1&2: Overtopping breach	3E-04 to 3E-03	0.1 to 1	3.5E-04		
PFM 13: Internal erosion into a sanitary sewer	1E-05 to 1E-04	0.3 to 3	3E-05		
PFM 7: Global instability of the levee	3E-07 to 3E-06	0.3 to 3	1E-06		
Total			3E-04 to 3E-03	0.1 to 1	3E-04

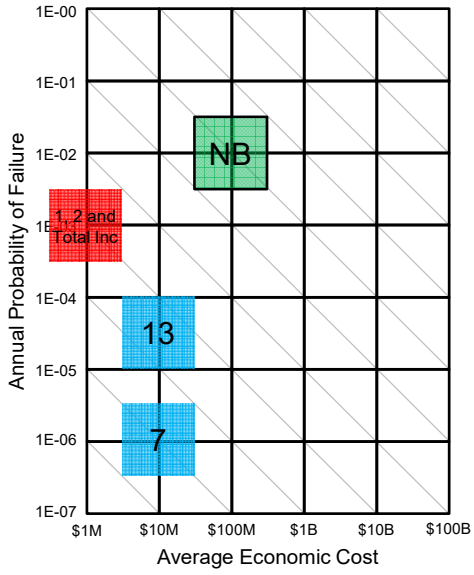
The individual incremental life safety risk estimates with and without intervention are portrayed in Figure ES-2.



With and without intervention

Figure ES-2 Individual Incremental Life Safety Risk Matrices

The incremental economic risk estimates with and without intervention are portrayed in Figure ES-3 and summarized in Table ES-2.



Potential Failure Modes
PFM 1: Levee overtopping erosion
PFM 2: Floodwall overtopping erosion
PFM 13: Internal erosion into a sanitary sewer
PFM 7: Global instability of the levee

With and without intervention

Figure ES-3 Incremental Economic Risk Matrices

Table ES-2.
Incremental economic risk summary (with and without intervention).

Potential Failure Mode	Annual Probability of Failure, APF (failures/year)	Average Incremental Economic Cost, $\bar{\$}$ ($/failure)	Average Annual Incremental Economic Cost, AAEC ($/year)
PFM 1&2: Overtopping breach	3E-04 to 3E-03	$300K to $3M	$1E03
PFM 13: Internal erosion into a sanitary sewer	1E-05 to 1E-04	$3M to $30M	$3E02
PFM 7: Global instability of the levee	3E-07 to 3E-06	$3M to $30M	$1E01
Total	3E-04 to 3E-03	$300K to $3M	$1E03

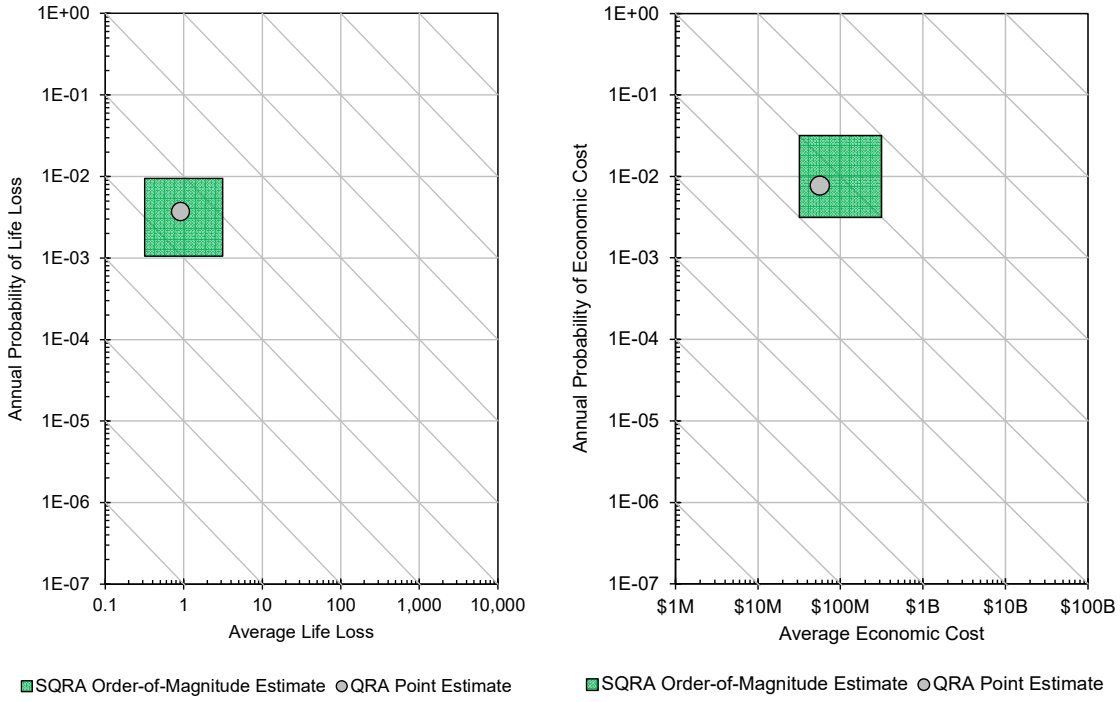


Figure ES-3 Non-Breach Risk Matrices

The annual probability of flooding with non-breach life loss was estimated between 1E-03 and 1e-02 floods per year. The average annual non-breach life loss ($AALL_{NB}$) was estimated to be 3E-03 lives per year. The weighted average non-breach life loss per flood ($\bar{N}_{NB}$) was calculated to be 0.9 lives per flood. Therefore, the estimated average non-breach life loss was estimated between 0.3 and 3 lives per flood.

The average annual non-breach economic cost ($AAEC_{NB}$) was estimated to be $400k per year. The weighted average non-breach economic cost per flood ($\bar{\$}_{NB}$) was calculated to be $56M per flood. Therefore, the average non-breach economic cost was estimated between $30M and $300M per flood.

There is high uncertainty in peak flood levels and durations due to the limited historic data available for the creek. There is uncertainty present in the estimated soil parameters due to the limited data collected to date and the unknown response of the levee fill and foundation material to short duration flood loading. Only minimal information is available about the condition of the sanitary sewer lines, but the uncertainty

should be reduced through televised inspections of the pipes prior to allowing any to remain in place within the zone of influence of the project.

Recommendations

1. Design culvert outfalls with one single passive flap gate closure as the flashy nature of flood events make active closures unlikely and the additional risk reduction of a secondary passive gate is minimal. (PFM 6; TRG 1, USACE).

2. Consider targeted sanitary sewer relocations to only those that pose the highest risk. These include pipes with manholes located in the construction footprint and associated pipes and any pipes that are in a deteriorating condition. (PFM 13; TRG 1&4, USACE).

3. Perform additional stability analysis for the detention basin, including appropriate water levels. (Stability PFMs; TRG 1, USACE).

4. Specify levee fill to use CL or ML and remove other soil classifications that are not fine grained. (All levee PFMs; TRG 4, USACE).

5. Ensure that, if I-walls are included, they have concrete or asphalt surface or armoring with riprap on the landside. (PFM 2; TRG 4, USACE).

6. Ensure all transitions from I-walls to levees have paved surface or armoring to mitigate overtopping erosion at these more critical locations. (PFM 1&2; TRG 4, USACE).

7. Inspect flap gates multiple times a year during routine inspections and perform post flood inspections for every high water event above a threshold to be determined by the PDT. (PFM 6; TRG 3, Sponsor).

8. Perform stability check on a T-wall with landside soil eroded to the base of the footing for top of wall loading. (PFMs 9, 11, 29; TRG 1, USACE).

9. Ensure pipes under the channel and under the levee are televised and show no defects before adopting continued use of the pipes. Ensure inspections are performed every five years and pipes are slip lined upon any sign of defect. (PFM 13; TRG 3, USACE and sponsor).

10. Ensure bridge replacement construction is conducted in a way that does not significantly raise life safety and economic risk to the community. The current plan is that bridge replacements will occur prior to levee and floodwall construction, so the construction specifications should ensure the bridges maintain appropriate conveyance and have emergency flood plans in place. (Existing risk; TRG 4, USACE and contractor).

1. Findings and Recommendations

Kansas City District has completed a Semi-Quantitative Risk Assessment (SQRA) for Upper Turkey Creek FRM Levee design in general accordance with Engineer Circular (EC) 1165-2-218 *USACE Levee Safety Program* (USACE 2021) and Dam and Levee Safety (DLS) Standard Operation Procedure (SOP) DLS-SOP-2023-03 *PFMA and SQRA Methodology* (USACE 2023c), and Appendix A of DLS-SOP-2023-04 *Periodic Assessments* (USACE 2023d). The SQRA consisted of a facilitated Potential Failure Mode Analysis (PFMA), a site visit, and a risk assessment of potential failure modes judged to be risk drivers.

1.1. Societal Incremental Life Safety Risk

A total of 37 potential failure modes (PFM) were identified by the SQRA team for consideration. Table 1 summarizes the risk-driving PFMs that were fully evaluated and are discussed in more detail in Chapter 7. The remaining 33 PFMs were not developed in detail because they were not considered to be risk drivers for the project. They are discussed in Appendix A.

Table 1.
Life safety risk-driving potential failure modes.

Potential Failure Mode	Description
PFM 1	Overtopping breach of the levee
PFM 7	Global instability of the levee
PFM 13	Internal erosion into a sanitary sewer

A risk matrix has been established to portray the incremental life safety risk (due to failure) with annual probability of failure (APF) on the vertical axis and the associated incremental life loss on the horizontal axis. Cell divisions correspond to order-of-magnitude ranges of APF and incremental life loss. The risk matrix is similar to the f-$\overline{N}$ diagram for portraying societal incremental life safety risk for quantitative risk analysis.

An approximate numerical estimate of APF and average incremental life loss was obtained for each PFM using the centroid (geometric mean) of the box (order-of-magnitude estimate). The total APF was calculated by summing the APFs for all primary risk-driving PFMs assuming they are mutually exclusive. The total average annual incremental life loss (AALL) was calculated by summing the product of the APF and average incremental life loss for all primary risk-driving PFMs. The weighted average incremental life loss ($\overline{N}$) was calculated by dividing by the total AALL by the total APF. Calculations are provided in Appendix C.

The societal incremental life safety risk estimates with and without intervention are portrayed i**n Figure 1 and summarized in Table 2.**Figure 1

Figure 1. Societal incremental life safety risk matrices.

Table 2.
Societal incremental life safety risk summary (with and without intervention).

Potential Failure Mode	Annual Probability of Failure, APF (failures/year)	Average Incremental Life Loss, $\bar{N}$ (lives/failure)	Average Annual Incremental Life Loss, AALL (lives/year)
PFM 1&2: Overtopping breach	3E-04 to 3E-03	0.1 to 1	3.5E-04
PFM 13: Internal migration into a sanitary sewer	1E-05 to 1E-04	0.3 to 3	3E-05
PFM 7: Global instability of the levee	3E-07 to 3E-06	0.3 to 3	1E-06
Total	3E-04 to 3E-03	0.1 to 1	3E-04

Additional details about the risk-driving PFMs and associated incremental life loss are provided in the following sections.

1.1.1. PFM 1 & 2: Overtopping breach of the levee and/or floodwall

PFM 1, Overtopping breach of the levee, was estimated to be the highest risk-driver of the system. The project is authorized to convey flood flows up to a 1% annual exceedance probability with 82.9% assurance of not overtopping. The current estimate of the overtopping frequency of the proposed design is a 1/130 AEP, however, additional hydraulic uncertainties are being incorporated into the design which may result in a higher design height and a lower overtopping AEP. The annual probability of failure from overtopping of the levee is estimated to be approximately one order of magnitude lower than the incipient overtopping probability due to the well-vegetated, lean clay, wide embankment that would be exposed to short durations of overtopping flows for extreme events. The flashy nature of the small, steep watershed results in sharp flood peaks and overtopping durations lasting an expected two hours or less for overtopping depths up to two feet. Additionally, the volume and extent of the leveed area is small, which would likely result in tailwater building quickly, which could limit the progression to a full breach and limit incremental consequences of a breach. The probability of unsuccessful intervention, however, is very likely due to the limited time to forecast a flood event and limited time to respond to quickly rising water levels.

PFM 2, Overtopping breach of the floodwall is included in this risk description as the team did not fully estimate the risk, as it was assumed the risk would be equal to or less than the risk of a levee breaching. T-wall floodwall types are expected to remain stable with erosion of the soil material above the footing and it is unlikely that erosion would reach this extent given the short duration. I-wall floodwall types would be more susceptible to instabilities from overtopping erosion, however, the current plan and one of the risk team's recommendations is to provide armoring or paving on the landside of I-wall features to mitigate overtopping erosion. Similarly to levees, unsuccessful intervention is very likely for the same reasons that the probability of failure without intervention is low – that the duration of flood events is extremely short due to the flashy nature of floods in this watershed.

Incremental life loss is expected to be low associated with overtopping breach of a levee or floodwall. Breach modeling indicates generally low peak breach flows and low breach volumes of inundation with no expected life loss associated with a failure up to top of levee. For overtopping depths of 1-2 feet, breach and non-breach conditions could result in life loss, with an estimate of 1 incremental life loss in both cases.

1.1.2. PFM 13: Internal migration into a sanitary sewer

PFM 13, Internal migration into a sanitary sewer, consists of areas where existing sanitary line that is not relocated beneath the zone of influence of the levee could be a location where a defect in the pipe could allow enough material to move through and eventually collapse the embankment. The team assessed different locations of sanitary infrastructure including manholes in and near the alignment and pipes through and parallel to the alignment. The team concurred that any manholes directly in the alignment of the levee or floodwall will need to be relocated, along with the incoming and outgoing pipes associated with the relocated manholes. However, existing pipes that are under the levee or wall or parallel to the levee or wall that are found to be in good condition and will continue to be inspected in the future could likely remain in place. Many pipes are 50 years old, but the pipe materials range from ductile iron pipe (DIP), clay, concrete, and PVC with design life ranging from 75-150 years so they may still be in good condition. Some pipes are larger (up to 42”) which could move a significant amount of material away over time, however, the flashy nature of storms makes it unlikely that enough material could be moved to cause failure in a single event. A good inspection program could ensure that these pipes continue to be in good service and any signs of defects would need to be replaced or relocated in the future. The team judged for any prior to overtopping failure scenarios, the incremental life loss could be around 1, so the team estimated life loss at 0.3 to 3 lives per failure.

1.1.3. PFM 7: Global instability of the levee

PFM 7,

1.2. Individual Incremental Life Safety Risk

Individual risk (IR) is the annual probability of life loss for the most exposed person or group. An estimate of the likelihood of the most exposed person or group losing their life was obtained from LifeSim software output (USACE 2023a). LifeSim computes a mean fatality rate at each structure over all LifeSim iterations, which includes those people that started in each structure and lost their life while evacuating. The structure inventory was reviewed for all flood scenarios, and the maximum of the mean fatality rates of .057 was multiplied by the estimated mean APF to obtain the mean individual risk estimate of 0.00002907 (2.91E-05). Therefore, the annual probability of life loss for the person or group most at risk was estimated between 1E-05 and 1E-04. This estimate is associated with LCL 2ft OT breach at Sta. RB 56+63 and the structure shown in Figure 2. The individual incremental life safety risk estimates with and without intervention are portrayed in Figure 3.

Figure 2. Structure used to estimate individual risk.

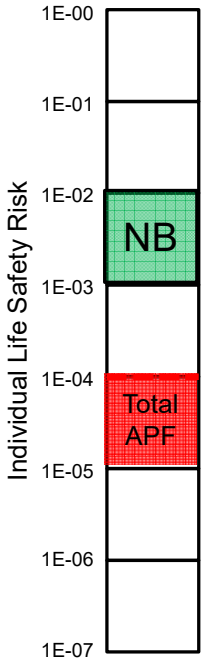

Figure 3. Individual incremental life safety risk matrix.

1.3. Incremental Economic Risk

A risk matrix has been established to portray the incremental economic risk (due to failure) with annual probability of failure (APF) on the vertical axis and the associated incremental economic cost on the horizontal axis. Cell divisions correspond to order-of-magnitude ranges of APF and incremental economic cost. The risk matrix is similar to the f-$\bar{\$}$ diagram for portraying incremental economic risk for quantitative risk analysis.

An approximate numerical estimate of APF and average incremental economic cost was obtained for each PFM using the centroid (geometric mean) of the box (order-of-magnitude estimate). The total APF was calculated by summing the APFs for all primary risk-driving PFMs assuming they are mutually exclusive. The total average annual incremental economic cost (AAEC) was calculated by summing the product of the APF and average incremental economic cost for all primary risk-driving PFMs. The weighted average incremental economic cost ($\bar{\$}$) was calculated by dividing by the total AAEC by the total APF. Calculations are provided in Appendix C.

The incremental economic risk estimates with and without intervention are portrayed in Figure 4 and summarized in Table 3.

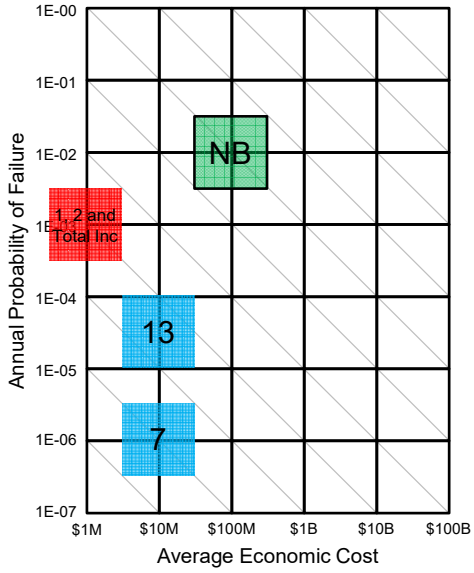

Figure 4. Incremental economic risk matrices.

Table 3.
Incremental economic risk summary (with and without intervention).

Potential Failure Mode	Annual Probability of Failure, APF (failures/year)	Average Incremental Economic Cost, $\bar{\$}$ ($/failure)	Average Annual Incremental Economic Cost, AAEC ($/year)
PFM 1&2: Overtopping breach	3E-04 to 3E-03	$300K to $3M	$1E03
PFM 13: Internal erosion into a sanitary sewer	1E-05 to 1E-04	$3M to $30M	$3E02
PFM 7: Global instability of the levee	3E-07 to 3E-06	$3M to $30M	$1E01
Total	3E-04 to 3E-03	$300K to $3M	$1E03

Additional details about the risk-driving PFMs and their associated incremental economic cost are provided in the following sections.

1.4. Non-Breach Life Safety Risk

Non-breach risk occurs when the flood capacity of the levee is exceeded. At this point, the levee transitions from managing the flood to passing the flood. For levees, the transition occurs at the overtopping stage. This elevation corresponds to the annual probability of non-breach inundation but may not result in life loss. The annual exceedance probability (AEP) when life loss begins to occur ($AEP_{N>0}$) is estimated based on available consequence information and judgment. The annual probability of flooding with non-breach life loss was estimated to be 1/250 AEP based on one foot of overtopping above top of levee (TOL) elevation (AEP_{TOL}). Therefore, the annual probability of flooding with non-breach life loss was estimated between 1E-03 and 1E-02 floods per year.

The non-breach life safety risk was estimated from a quantitative risk analysis (QRA). The stage-frequency curve in Chapter 4 defines a continuous loading relationship between peak water surface elevation and AEP. Z-variate interpolation was used to calculate the AEP for intermediate peak water surface elevations. The overtopping without breach life loss scenarios in Chapter 6 define a continuous relationship between peak water surface elevation and non-breach life loss. Linear interpolation was used to calculate non-breach life loss for intermediate peak water surface elevations. Average non-breach life loss estimates were weighted 0.45 for daytime and 0.55 for nighttime.

The average annual non-breach life loss ($AALL_{NB}$) was estimated to be 0.3 lives per year. The weighted average non-breach life loss per flood ($\overline{N}_{NB}$) was calculated by dividing the $AALL_{NB}$ by the annual probability of flooding with non-breach life loss resulting in 0.9 lives per flood. Therefore, the average non-breach life loss was estimated between 0.3 and 3 lives per flood. Calculations are provided in Appendix C. The results are plotted on a separate non-breach life safety risk matrix, similar to the societal incremental life safety risk matrix previously described. However, the vertical axis is labeled “annual probability of life loss,” and no tolerable risk limit lines are shown since they are not applicable. The non-breach life safety risk is portrayed in Figure 5.

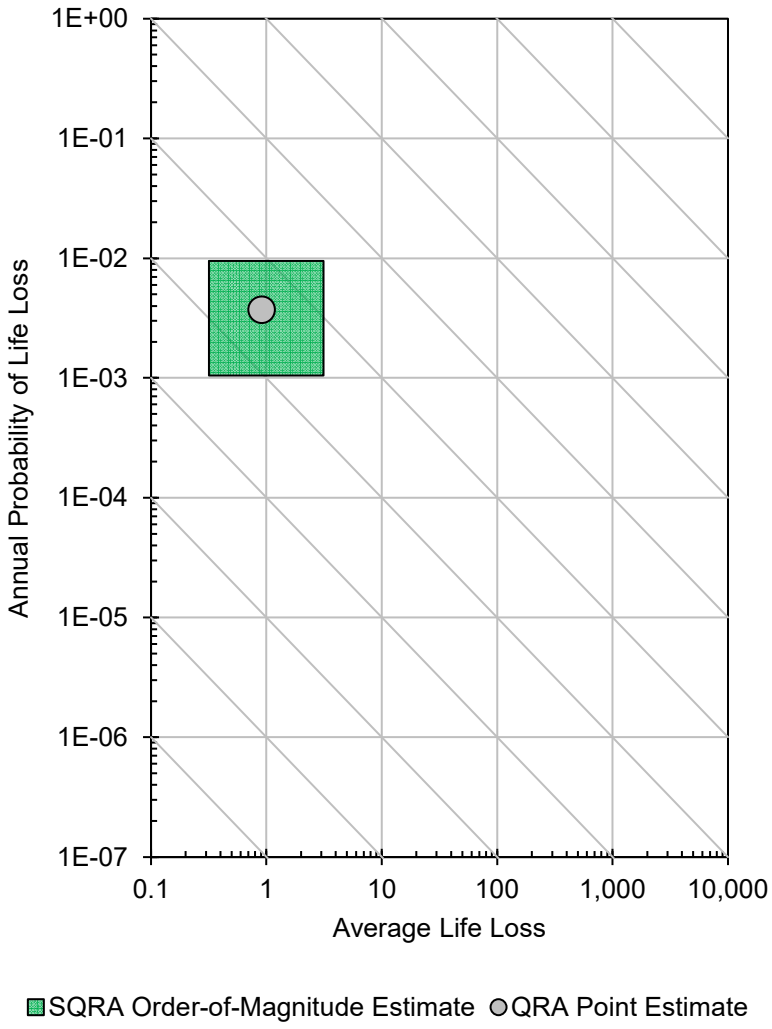

Figure 5. Non-breach life safety risk matrix.

The levee system overtops at an estimated 1/130 AEP. Due to the short duration of overtopping flows, non-breach life loss does not occur until one foot of overtopping depth, approximately 1/250 AEP. Non-breach life loss is estimated to occur for depths of overtopping greater than 1 foot on the right bank during the day in the highly commercial area or on the left bank at night where the leveed area has more residential structures.

1.5. Non-Breach Economic Risk

Non-breach risk occurs when the flood capacity of the levee is exceeded. At this point, the levee transitions from managing the flood to passing the flood. For levees, the transition occurs at the overtopping stage. This elevation corresponds to the annual probability of non-breach inundation but may not result in flood damages. The annual exceedance probability (AEP) when flood damages begin to occur ($AEP_{\$>0}$) is estimated based on available consequence information and judgment. The annual probability of flooding with non-breach economic cost was estimated to be 1/130 AEP based on the top of

levee (TOL) elevation (AEP_{TOL}). The annual probability of flooding with non-breach economic cost was estimated between 3E-03 and 3E-02 floods per year.

The non-breach economic risk was estimated from a quantitative risk analysis (QRA). The stage-frequency curve in Chapter 4 defines a continuous loading relationship between peak water surface elevation and AEP. Z-variate interpolation was used to calculate the AEP for intermediate peak water surface elevations. The overtopping without breach economic cost scenarios in Chapter 6 define a continuous relationship between peak water surface elevation and non-breach economic cost. Linear interpolation was used to calculate non-breach economic cost for intermediate peak water surface elevations

The average annual non-breach economic cost ($AAEC_{NB}$) was estimated to be $400k per year. The weighted average non-breach economic cost per flood ($\bar{\$}_{NB}$) was calculated by dividing the $AAEC_{NB}$ by the annual probability of flooding with non-breach economic cost resulting in $56M per flood. Therefore, the average non-breach economic cost was estimated between $30M and $300M per flood. Calculations are provided in Appendix C. The results are plotted on a separate non-breach economic risk matrix, but the vertical axis is labeled “annual probability of economic cost.” The non-breach economic risk is portrayed in Figure 6.

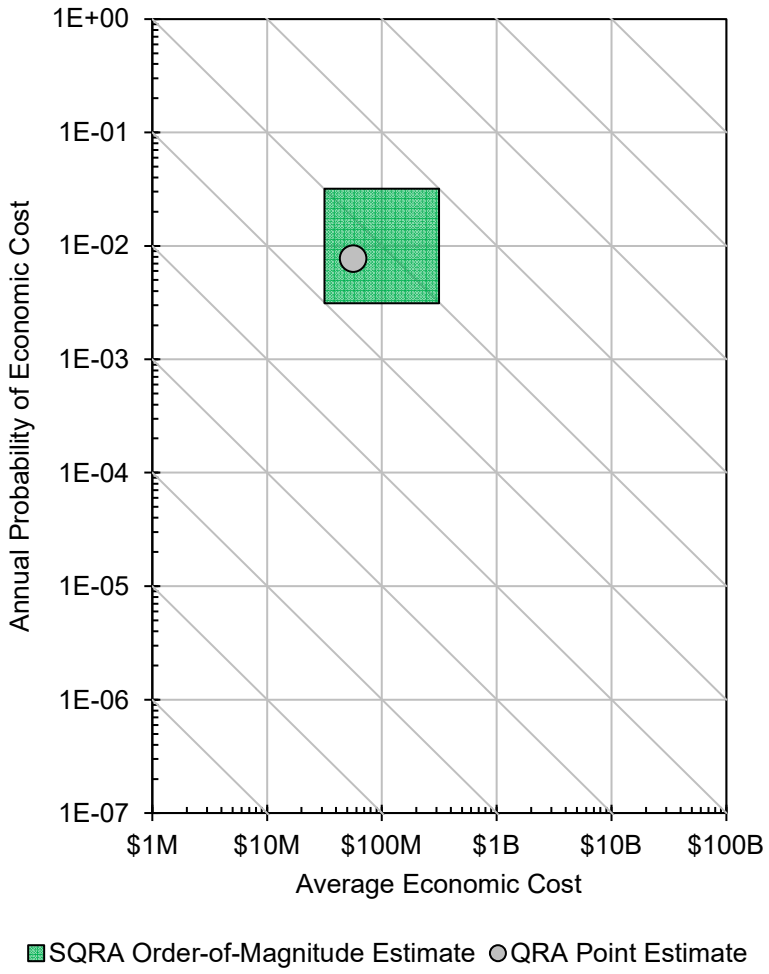

Figure 6. Non-breach economic risk matrix.

Non-breach economic risk is limited by the limited leveed area extent and volume associated with breaching. The primary impacted area is commercial development along the right bank levee.

1.6. Major Findings and Understandings from the Risk Assessment

The following major findings and understandings were developed by the SQRA team:

- The proposed sheet pile for the T-wall does not mitigate intended potential failure mode
- As part of this effort, the design team indicated they will move toward including armoring of transitions to mitigate vulnerabilities to overtopping flows.
- Culverts through the levee of less than 36” diameter are proposed to have a single passive closure, which meets guidance in EM 1110-2-2902.

- The current plan for two passive flap gates for culverts larger than 36” meets the intention of EM 1110-2-2902 to have two means of closure, however, it does not meet the criteria that one of the closures is an active closure. The PDT and risk team concurred that the flashy nature of flooding would not allow the eight culvert locations that are greater than 36” to be actively closed ahead of a flood event.

- There is extensive existing sanitary sewer infrastructure that falls along and near the proposed alignment.

- The flashy nature of flood loading is not expected to approach steady state seepage conditions for all possible flood conditions.

- The levee lies within a small watershed and any creek flooding is associated with heavy rainfall over the entire watershed including the leveed area

- As a new system, it is expected that the entire alignment of both levee systems is expected to overtop at approximately the same frequency.

- Bedrock is not deep – approximately the same elevation as the channel bed for the entire alignment

- Pedestrian bridges remain in place and will likely have flood inundation that exceeds the low chord.

- Life safety risk associated with a breach or overtopping is low based on the current population and structures at risk. If the PAR, development, or zoning changes, this life safety risk could change.

- The channel banks are stabilized with a limestone wall that regularly experiences loss of some of the limestone blocks. The Merriam Drainage District regularly repairs these blocks and works to keep rodents from causing instabilities. There are instances of more permanent repair measures along the wall including concrete placement to stabilize toe scour.

- Hydraulic modeling indicates up to 2 feet of super elevation, which needs to be verified.

1.7. Recommendations

Tolerable Risk Guidelines (TRG) are used for risk-informed decision making within the USACE Dam and Levee Safety Programs. These guidelines are the criteria USACE uses to determine if the risks associated with dams and levee systems are “tolerable.” The four TRG are provided below.

- TRG 1 (Understanding the Risk): Society is willing to live with the risk associated with the dam or levee to secure the benefits provided by the dam or living and working downstream or in the leveed area.

- TRG 2 (Building Risk Awareness): There is a continuation of recognition and communication of the dam or levee risk.

- TRG 3 (Fulfilling Daily Responsibilities): The risks associated with the dam or levee system are being properly monitored and managed by those responsible for managing the risk.

- TRG 4 (Actions to Reduce Risk): There are no cost-effective, socially acceptable, or environmentally acceptable ways to reduce risks.

Recommendations were formulated based on these four TRG to manage and reduce risk. Additional details about the hazard, performance, and consequences can be found elsewhere in this report. The following recommendations were developed by the SQRA team.

11. Design culvert outfalls with one single passive flap gate closure as the flashy nature of flood events make active closures unlikely and the additional risk reduction of a secondary passive gate is minimal. (PFM 6; TRG 1, USACE).

12. Consider targeted sanitary sewer relocations to only those that pose the highest risk. These include pipes with manholes located in the construction footprint and associated pipes and any pipes that are in a deteriorating condition. (PFM 13; TRG 1&4, USACE).

13. Perform additional stability analysis for the detention basin, including appropriate water levels. (Stability PFMs; TRG 1, USACE).

14. Specify levee fill to use CL or ML and remove other soil classifications that are not fine grained. (All levee PFMs; TRG 4, USACE).

15. Ensure that, if I-walls are included, they have concrete or asphalt surface or armoring with riprap on the landside. (PFM 2; TRG 4, USACE).

16. Ensure all transitions from I-walls to levees have paved surface or armoring to mitigate overtopping erosion at these more critical locations. (PFM 1&2; TRG 4, USACE).

17. Inspect flap gates multiple times a year during routine inspections and perform post flood inspections for every high water event above a threshold to be determined by the PDT. (PFM 6; TRG 3, Sponsor).

18. Perform stability check on a T-wall with landside soil eroded to the base of the footing for top of wall loading. (PFMs 9, 11, 29; TRG 1, USACE).

19. Ensure pipes under the channel and under the levee are televised and show no defects before adopting continued use of the pipes. Ensure inspections are performed every five years and pipes are slip lined upon any sign of defect. (PFM 13; TRG 3, USACE and sponsor).

20. Ensure bridge replacement construction is conducted in a way that does not significantly raise life safety and economic risk to the community. The current plan is that bridge replacements will occur prior to levee and floodwall construction, so the construction specifications should ensure the bridges maintain appropriate conveyance and have emergency flood plans in place. (Existing risk; TRG 4, USACE and contractor).

2. Background

2.1. Location and Purpose

The Upper Turkey Creek FRM project is located in the City of Merriam, in Johnson County, Kansas. Turkey Creek is a right-bank tributary of the Lower Kansas River located in Johnson and Wyandotte counties, Kansas, between approximate river miles (RMs) 2.7 to 3.7. Figure 7 shows the location of the Upper Turkey Creek FRM project.

The project was originally authorized for a feasibility study by the Resolution of the Committee on Transportation and Infrastructure, U.S. House of Representatives, Docket 2616, adopted 16 February 2000. Authority for the design and construction of this project was provided in the Water Infrastructure Improvements for the Nation Act (WIIN Act) of 2016, Public Law (PL) 114-322, as recommended in the report of the Chief of Engineers dated 22 December 2015, based on the 15 March 2015 Feasibility Report with Integrated Environmental Assessment. Funding was provided in the amount of $500,000 under the fiscal year (FY) 2022 Omnibus funding-Community Project Funding/Congressionally Directed spending and in the amount of $23.9 million under the Infrastructure Investment and Jobs Act, PL 117-58.

The non-federal sponsor for this project is the City of Merriam, Kansas. Johnson County, Kansas, contributes to the city's cost share and is involved in the design phase. Part of the Turkey Creek channel in the study area is operated and maintained by the Merriam Drainage District (MDD) under a state charter that provides MDD authority independent of the City of Merriam or Johnson County. MDD may be responsible for operation and maintenance of this project in the future.

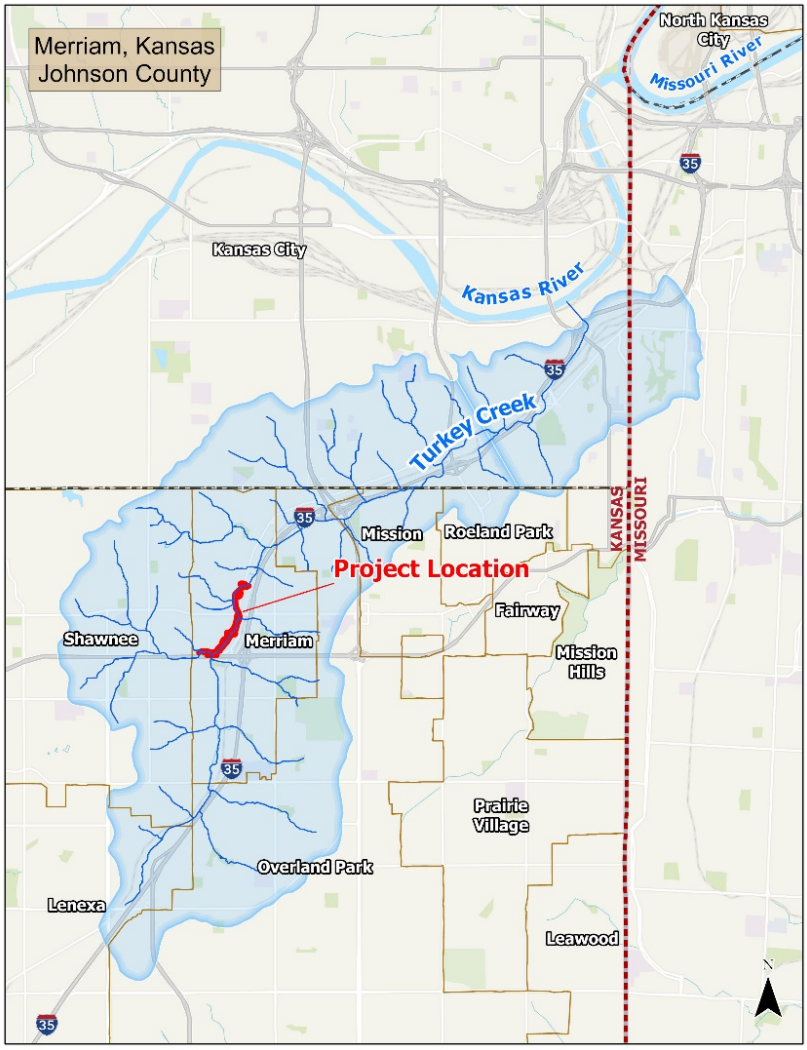

Figure 7. Project location.

2.2. Project Description and Pertinent Data

The main components of the project are shown in Figure 8 and include earthen levee, floodwalls, bridge replacements, detention basin, and drainage structures. The overall project is approximately 1.5 miles long. A majority of the existing limestone block wall will remain, but the floodwall/levee will be set back so the projected toe will not be impacted by the existing wall. The maximum levee height is approximately 10 feet, and the floodwall height ranges from 6 to 14 feet. The levee embankment consists of compacted impervious material.

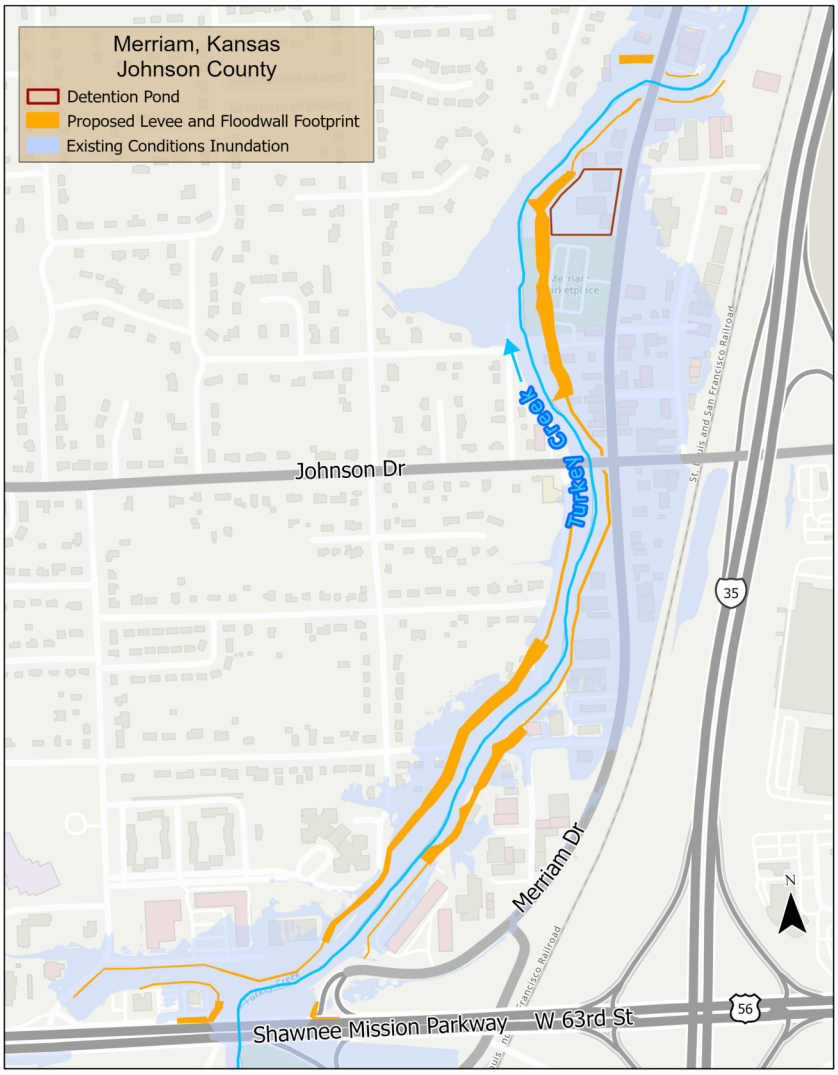

Figure 8. Project overview.

2.3. Levee Embankments

There is roughly 4,000 linear feet of levees with a maximum levee height of approximately 10ft along the left and right banks of this approximately 1.5-mile-long project. The levee embankment consists of compacted impervious material with a 10ft wide crest and 3:1 side slopes. A majority of the existing limestone block wall will remain, but the levee will be set back so the projected toe will not be impacted by the existing wall.

The levee stability design is controlled by drained strength. To meet the required 1.4 factor of safety for steady state stability, some of the levee embankment requires sand drains or stability berms and sand drains. See Figure 9 for a typical levee section showing the stability berm and sand drain. During the SQRA elicitation, the team investigated the risk of not designing to steady state criteria. That discussion can be found in Chapter 7.

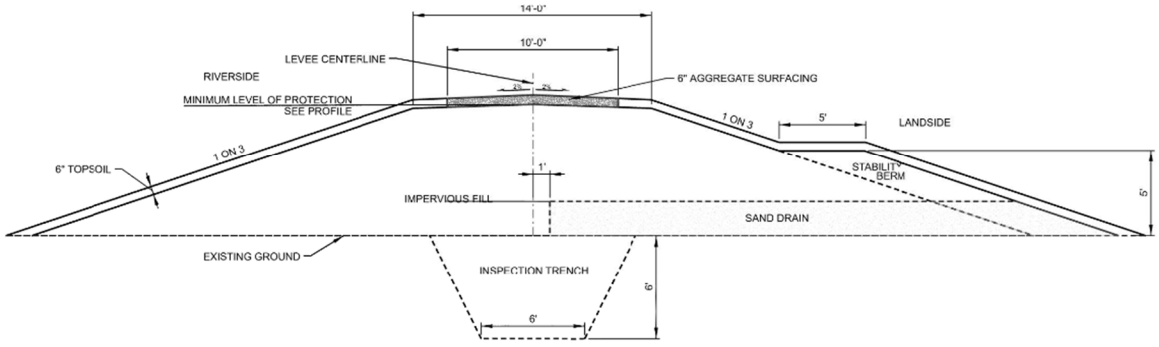

Figure 9. Levee Embankment Typical Section.

2.4. Floodwalls

There is roughly 6,000 linear feet of spread footing floodwalls ranging from 6 feet to 14 feet in height along the left and right banks of this approximately 1.5 mile long project. A majority of the existing limestone block wall will remain, but the levee will be set back so the projected toe will not be impacted by the existing wall.

In areas where floodwalls are required, the original design intent was to use I-walls where feasible, based on their smaller footprint. Based on Table 9.4 in EM 1110-2-2502 (12/2022), for the Unusual load category, using soft clay foundation type, I-walls used as floodwalls should be limited to a maximum wall height of 7 feet.

During initial I-wall analysis, the required embedment depth for rotational stability is greater than depth to bedrock for all configurations, resulting in selection of T-wall instead of I-wall for all floodwall areas. The I-wall design is controlled by drained strength. During the SQRA elicitation, the team investigated the risk of not designing to steady state criteria. That discussion can be found in Appendix A. See Figure 10 for Floodwall Typical Section.

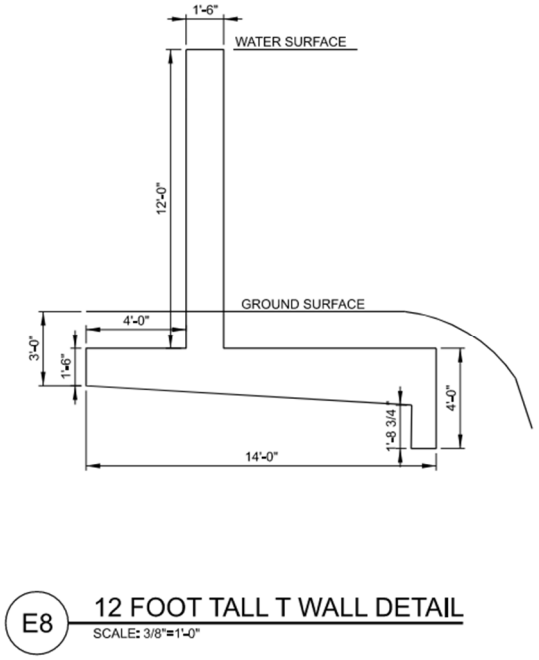

Figure 10. Floodwall Typical Section.

2.5. Relocations

Due to the urban and developed nature of this project location, there are several existing utilities within the project footprint. Existing pipelines crossing the levee that do not meet current USACE criteria will be replaced with pipelines that are compliant. If feasible, all utilities should be located outside of the influence zone. The influence zone at levees is identified as the 15-foot distance from the centerline of the levee on both the riverside and landside. The influence zone at floodwalls is identified as the 15-ft distance from the outside stem wall face or a minimum of 8-ft distance from the footer of the floodwall base, whichever is greater. Existing pipe strengths, unless otherwise known, will be assumed to be that required by USACE criteria at the time of their installation. Pipe condition shall be determined by field assessment.

Gravity lines should be relocated under the crest of the levee raise if it cannot be located outside of the influence zone.

Pressure lines should be relocated over the crest of the levee raise if it cannot be located outside of the influence zone. Pipes crossing over the levee shall have enough cover for local frost protection, one foot minimum. 10:1 slopes on either side of the raised utility to allow for vehicular traffic. Pressure pipes need to be designed and constructed to prevent and control seepage and erosion along the pipe.

Before consideration is given to allowing a pressure pipe to remain through or beneath the levee, the pipe owner will provide an engineering study to support their request. The owner, regardless of the type of pipe, must show adequate capability as to the condition of the existing pipe. An agreement will then be formed between the owner and the levee district to the effect that should repairs to a pipe in the levee become necessary, the pipe will be abandoned, grouted, and relocated over the levee.

Pipes that have been abandoned and do not meet criteria will be removed or grouted accordingly. Pipelines that are currently active but are to be abandoned as part of this project will be removed or grouted full in accordance with criteria.

Utility structures should be located outside of the influence zone if feasible. Structures that are placed inside of the influence zone must be evaluated to mitigate any potential breach. Existing and proposed storm pipes should have a gate box on the riverside. Sanitary pipes should have a manhole located on the landside when feasible. During SQRA elicitation, the team investigated the risk of only removing pipe sections that impact construction and grout-fill remaining lines to abandon within construction limits. That discussion can be found in Chapter 7 and Appendix A.

2.6. Gravity Drainage

There are approximately 27 gravity drainage crossings under the levee/floodwall. The portion of the existing drainage pipe crossing the levee or floodwall will be replaced with reinforced concrete pipe (RCP) and any existing pipes smaller than 24-inch will be upsized to 24-inch with this project. See Figure 11 for an example of an existing drainage crossing.

Figure 11. Existing CMP Crossing Limestone Block Wall.

EM 1110-2-2902, *Conduits Pipes and Culverts Associated with Dams and Levee Systems* lists the closure type requirements for different flood rise conditions. See Figure 12 for a typical drainage crossing. Table 4 summarizes the closure requirements.

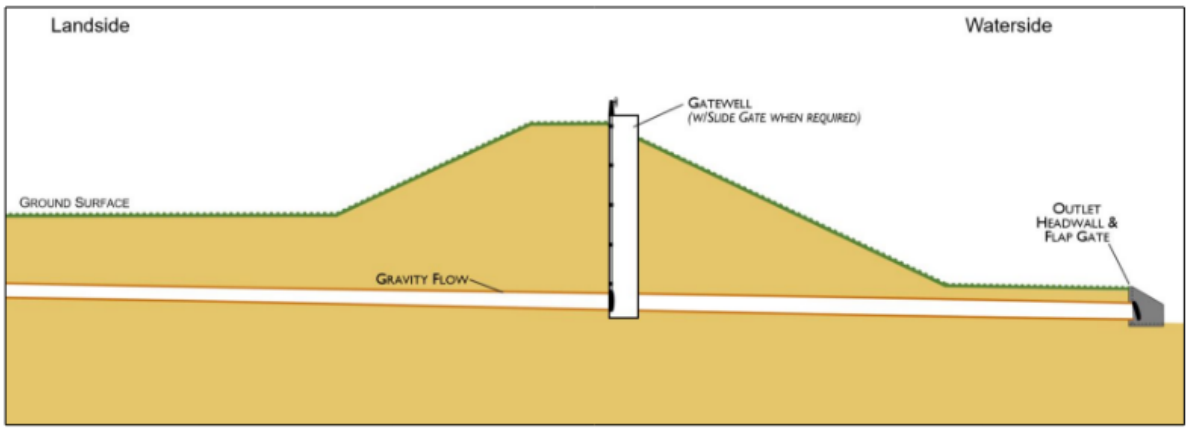

Figure 12. Typical Drainage Crossing Through Levee Embankment.

Table 4.
Closure Type Requirements[1]

Flood Rise[2]	Pipe Diameter (inches)	Closure Configuration
Fast	<36	One Passive
Fast	≥36	One Passive AND One Active
Slow	<36	One Passive OR One Active
Slow	≥36	One Passive AND One Active OR Two Active

[1]Table 9-1 of EM 1110-2-2902
[2]Fast flood rise refers to floods capable of rising to a flood stage with less than 12 hours prediction time. Slow flood rise refers to floods capable of rising to a flood stage with greater than 12 hours prediction time

The flood rise condition for our project is considered fast since there is less than 12 hours of prediction time. The Project Delivery Team (PDT) recommends a deviation from Table 9-1 of EM 1110-2-2902 to use one passive closure at the outlet for all pipes including those greater than or equal to 36 inches. This recommendation affects 7 of the 27 drainage crossings and is based on the short duration of the design storm. There is also a concern that it is not feasible for the Sponsor to manually operate more than 7 sluice gates throughout the project with less than 12 hours prediction time.

2.7. Limestone Wall

The existing limestone block retaining wall is a gravity block wall with no reinforcements tying the blocks together. The individual blocks are approximately 6 feet long, 2 feet deep, and 14 to 18 inches tall. The face of each block in the stack is offset approximately 2 inches back from the face of the block below it. There is no drain behind the wall. The wall was backfilled with local soil which appears to be mainly

clay. In some recent replacement sections of wall, filter fabric and aggregate backfill were placed behind the wall. This limestone block wall is considered a non-engineered structure and was not considered to provide support to the proposed levees or floodwall.

Figure 13. Existing Limestone Block Wall.

2.8. Bridge Replacements

There are two roadway bridges within the project limits that must be removed and replaced. Due to increased water elevations, the existing bridges at Johnson Drive and Merriam Drive do not meet the required uplift or overturning criteria to remain. The new bridge for Merriam Drive is planned tobe a Kansas Department of Transportation (KDOT) slab bridge. The new bridge at Johnson Drive will require further analysis and a new bridge will be selected at the 65 percent phase.

Figure 14. Merriam Drive Bridge.

Figure 15. Johnson Drive Bridge.

2.9. Non-Project Features

The Shawnee Mission Parkway immediately east of Turkey Creek acts as a non-project portion of the flood protection system which prevents inundation that builds up in Chatlain Park from flowing into the proposed levee interior. An upstream view of the embankment is shown below in Figure 16

Figure 16. Shawnee Mission Parkway roadway embankment.

2.10. Site Characterization

2.10.1. Geologic Setting

The Turkey Creek Flood Control Project is in the Osage Plains region of the central lowland physiographic region. The generally rolling to level upland has been eroded by Turkey Creek and associated drainageways to create vertical relief of more than 200 feet between the highlands and lowlands of the Turkey Creek channel. Bedrock is exposed in numerous places along the valley walls and in the creek bottom.

2.10.2. Bedrock Geology

Bedrock is exposed in numerous places along the valley walls and in the creek bottom. Bedrock consists of sedimentary bedrock of the Pennsylvanian Age. The rock units along the creek bottom and the valley walls are alternating shales and limestones of the Bronson and Linn subgroups of the Kansas City Group. The high hilltops outside the study area are part of the Zarah subgroup.

The valley walls are eroded into the formations of the Linn subgroup, which are predominantly shales with several limestones. From the top down, the rock units are the Iola Limestone Formation, the Chanute Shale Formation, the Drum Limestone Formation, and the Cherryvale Formation. The Cherryvale Formation consists of the following members in descending order: Quivira Shale, Westerville Limestone,

Wea Shale, Block Limestone, and Fontana Shale. Of particular note is the Westerville Limestone, which in the upper portion is highly variable in lithology, usually consisting of cross-bedded oolitic limestone but may contain varying amounts of shale. The lower 3 to 4 feet is consistently hard, dense limestone. Vertical faces of the Westerville Limestone in this area may not be stable over the long term and the unit may be water bearing.

The valley floor is cut into the formations of the Bronson Subgroup, which are predominately limestones with several shales.In descending order, the rock units are the Dennis Limestone Formation, the Galesburg Shale Formation, and the Swope Limestone Formation. The Dennis Formation consists of the Winterset Limestone Member and the Stark Shale Member. The Swope Limestone Formation consists of the Bethany Falls Limestone Member, the Hushpuckney Shale Member, and the Middle Creek Limestone Member. The upper several feet of the Bethany Falls Limestone consist of a nodular limestone in a shale matrix and is referred to as the peanut zone.

The intervening Galesburg Shale Formation consists of Canville Limestone (usually absent) and the Galesburg Shale. Differentiating the Galesburg Shale from the overlying Stark Shale is sometimes difficult. The two shales are frequently grouped together as the Stark-Galesburg Shale even though they are from different formations. Review of KDOT profiles for I-35 in the project vicinity indicates a noticeable thickening of this unit to the north, with the appearance of the Canville Limestone.

The present Turkey Creek alignment generally flows on or near the top of the bedrock surface. The exposed bedrock in the channel is either shale or Winterset Limestone in the upper reaches while Bethany Falls Limestone is present in the lower reaches near the tunnel entrance.

2.10.3. Unconsolidated Deposits

The soils in the Turkey Creek flood plain area are mostly alluvial deposits overlying eroded bedrock surface. The surficial soils generally are comprised of unclassified fill overlying lean clay with layers of clayey gravel found at depth near the bedrock surface. The native alluvial silts and clays belong to Onawa-Haynie Association. The hillside soils in the valley are derived from loess and residual soils of the Knox-Ladoga Association.

The native lean clay deposits (CL) are described as medium to stiff and very stiff consistency materials with liquid limits less than 50 percent and plasticity indices varying from about 13 to 29 percent. Natural moisture contents reported in the exploration data vary from 21 to 29 percent.

There are occasional layers of fat clay deposits within these natural deposits. The fat clays have liquid limits on the order of 52 percent.

Groundwater is generally encountered a few feet above the bedrock surface and fluctuates with ground surface elevation. A relatively thin layer (approximately 4 feet) of clayey gravel immediately above the bedrock is a water bearing layer.

Some fills from the channelization of Turkey Creek were randomly placed in the project area. Fills from I-35 rock cuts were placed along the left bank and the construction of a low-level levee and railroad yard on the right bank resulted in fills of unclassified materials. The fills have been in place for many years and appear to have consolidated under their own weight.

Some evidence of dumped debris along the right bank and within the flood plain area exists. This dumped debris is generally unsuitable material for use in engineered fills.

3. Periodic Inspection

The semi-quantitative risk assessment did not include a periodic inspection. Therefore, this chapter is left blank intentionally.

4. Hydrologic Hazards

4.1. Introduction

USACE uses a risk-informed approach where risk assessments and deterministic design standards provide more information for decision makers. The primary objectives of the hydrologic hazard analysis for levees to support a semi-quantitative risk assessment (SQRA) are:

- Characterize the dominant flood hazard(s) for the watershed and system and document/describe the history of past flood events.
- Estimate the discharge-frequency relationship and maximum flood events, considering effects of any upstream regulation.
- Characterize the typical duration of flood events and the annualized water surface elevation-duration relationship.
- Estimate the water surface elevation-discharge relationships and uncertainties across the entire levee system through hydraulic modeling, including the effects of coincident flooding sources.
- Provide water surface elevation-frequency relationship at numerous index locations throughout the system and through development of system water surface profiles along the levee.
- Summarize risks related to overtopping flows and outflanking of the levee system and provide preliminary expected annual exceedance probability of overtopping inundation.
- Document other known hydrologic and hydraulic concerns and uncertainties for the levee system such as channel or bank erosion, sedimentation, stage impacts, wind-wave or wake impacts, ice and debris, known interior drainage issues, or water management operational changes.

4.2. Background Data

Table 5 provides pertinent information for the current effective design of the levee system. The SQRA is taking place during the design of Upper Turkey Creek levee. Authorization is for the design 0.01 AEP (1/100-yr) event with an assurance of 82.9%. The levee height has been adjusted to meet the 85% assurance to meet USACE certification standards given negligible height increases are needed. The updated levee design passes the 0.01 AEP design flow with an assurance of 85%, surpassing the authorized assurance level. There is desire to modify the levee profile to have a designed overtopping location that would be both hydraulically advantageous and of low consequences. This is one of the risk informed design decisions that are to be discussed during the risk assessment.

The flood of record on Turkey Creek occurred on October 4th, 1998. At this time, there were no active flow recording gages. Peak flow was estimate using a hydraulic model based on surveyed high-water marks as part of the USACE 2003 General Reevaluation Report (GRR).

Table 5.
Pertinent information for the levee system.

Description	Value
Authorization	Water Infrastructure Improvements for the Nation Act (WIIN Act) of 2016, Public Law 114-322
Watercourse(s)	Turkey Creek (RM 7.3 to 6.1)[1]
Watershed	Turkey Creek Basin
Drainage Area[3]	12.3 square miles

[2]Flood of record was estimated using hydraulic modeling and highwater marks. Not observed gage flow
[3]Upstream Drainage area from downstream extent of project

The Turkey Creek at Kansas City, KS (USGS 06892940) gage conversion between the North American Vertical Datum of 1988 (NAVD88) and National Geodetic Vertical Datum of 1929 (NGVD29) is as follows:

$$\text{NAVD88} = \text{NGVD29} + 0.32 \text{ ft} \quad (1)$$

Table 6 summarizes historical flood events at Turkey Creek at Kansas City, KS (Southwest Blvd). This gage is downstream of the project extents. This gage was used as a common reference point to report historic Turkey Creek flooding. Documentation reported estimated flood magnitudes at various locations along Turkey Creek, so all flows were scaled to Turkey Creek at Kansas City, KS using a basin area ratio.

Table 6. Historical flood events.

Date	Peak Discharge (cfs)	Peak Water Surface Elevation (ft-NAVD88) at Turkey Creek at Kansas City, KS Gage (USGS 06892940)	Peak Gage Height (ft)[1] at Turkey Creek at Kansas City, KS Gage (USGS 06892940)	Source Location (Basin Area Ratio)
04 October 1998	23,800 cfs[3]	792.36[2]	29.94	Southwest Blvd.
21-22 April 1944	15,900 cfs[3]	-	-	Johnson Dr. (1.41)

[2]Surveyed high water mark
[3]Estimated flow

The Upper Turkey Creek levee project is located on Turkey Creek from approximately river mile 7.3 to 6.1 in Johnson County, Kansas. The levee is located along Merriam, Kansas approximately 8 miles southwest of the Kansas City district office in downtown Kansas City, Missouri. Figure 7 provides an overview of the project location, and Figure 17 provides an overview of the leveed area. The levee protection project is currently in design as of April 2025. The levee is being designed by USACE. It is not yet determined who the sponsor for the levee will be, but it will likely be the city of Merriam or the Merriam Drainage District. The drainage area above the levee system is approximately 12.3 square miles and is characterized as heavily urbanized. USGS StreamStats (https://streamstats.usgs.gov/ss/) characterizes the upstream drainage area as 100% developed and 43.2% impervious according to the 2011 NLCD layer. Flood events are influenced by intense local storm events that lead to large volumes of surface runoff mainly during the spring and summer seasons but can occur in any month with sufficient rainfall. Turkey Creek flooding is not significantly driven by antecedent conditions and can occur from one single storm event with no prior rainfall.

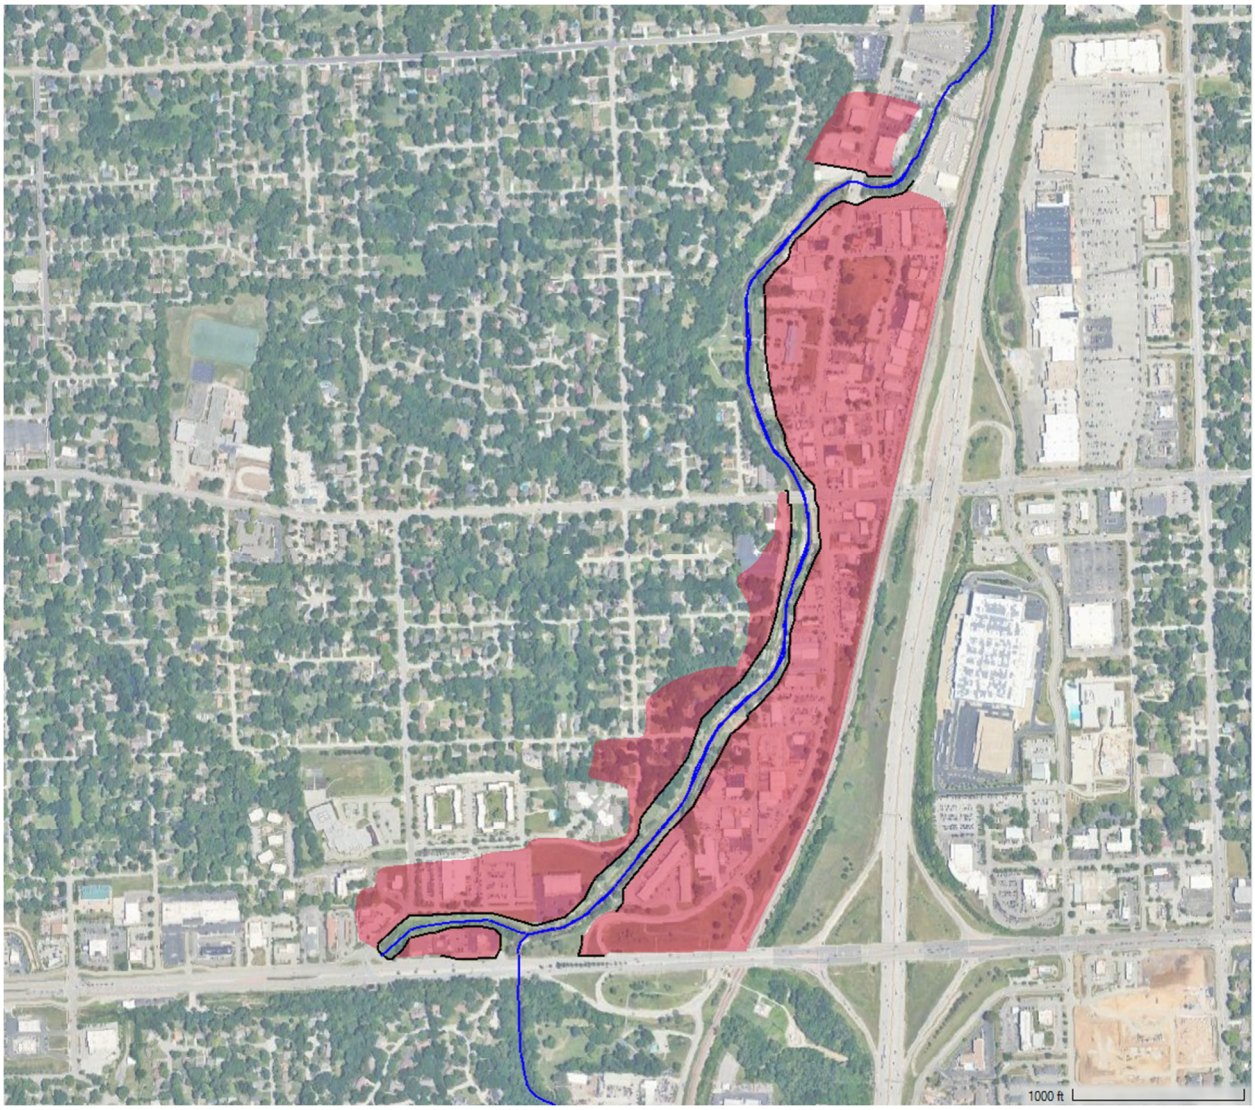

Figure 17. Proposed leveed area.

Table 7 provides pertinent information for the two Lower Turkey Creek levee projects which were approximately 2-3 miles downstream of the Upper Turkey Creek project area. There are no other levee systems along the Turkey Creek watershed.

Table 7. Pertinent information for neighboring levee systems.

Description	Value

4.2.1. Data Sources

There is a notable lack of continuous and consistent period of record data for gages within the Turkey Creek watershed. Majority of gages along Turkey Creek are operated by StormWatch (SW) (https://www.stormwatch.com), a county wide flood warning system managed mostly by Johnson County, KS but extends to the larger Kansas City metro as well. Stormwatch has one gage located within the project extents, Johnson Drive at Turkey Creek (SW TU04). This gage along with the rest of the storm gages only record stage. Figure 18 provides locations of the StormWatch gages along Turkey Creek. All gages record both river stage and rainfall, with the exception of TU09, which records rainfall only.

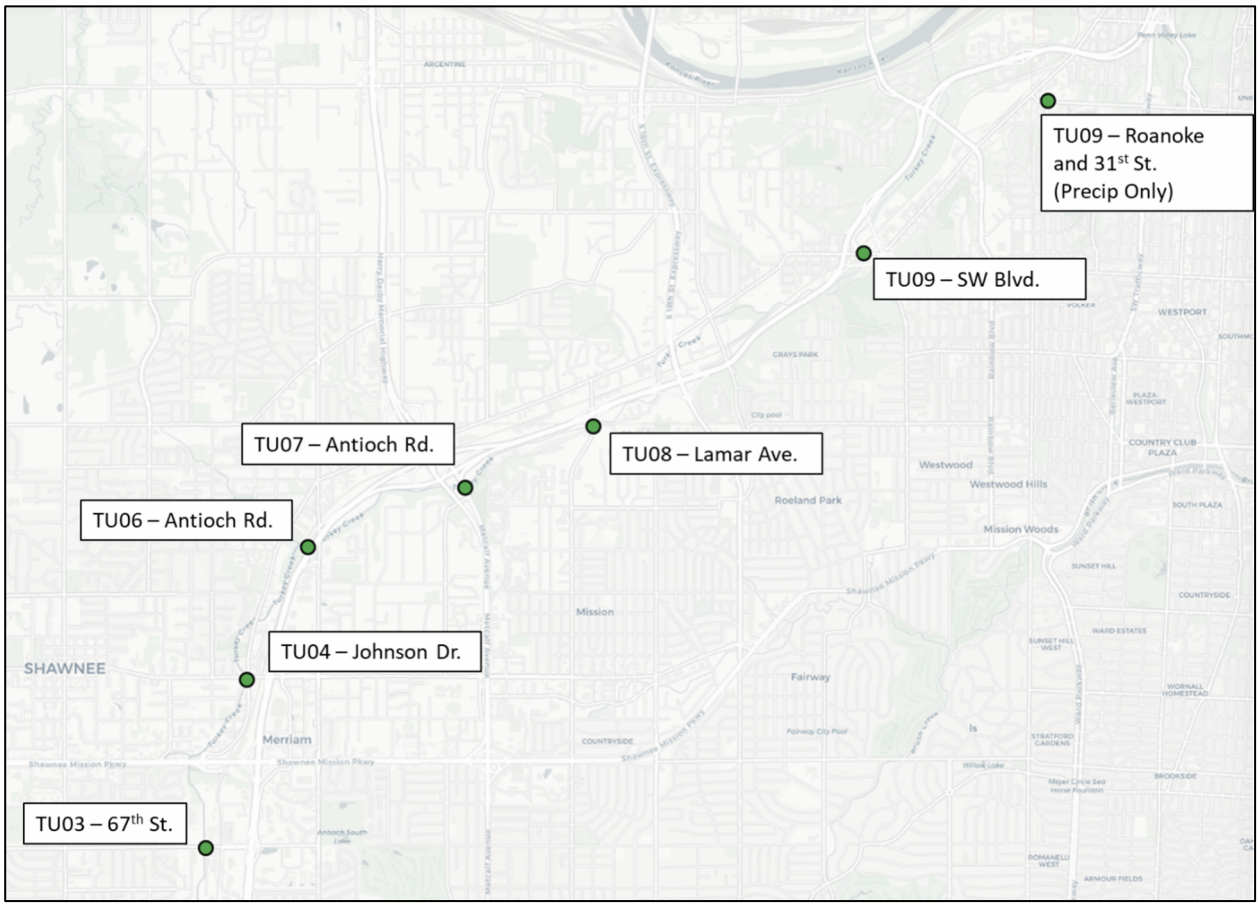

Figure 18. Turkey Creek StormWatch gages.

Johnson Drive at Turkey Creek (SW TU04) has a stage period of record from 1998 to current day. The StormWatch gages seemingly have the capability to record instantaneous data, even sub-15-minute increments, but appear to only do so during times of flow increases. An example of this is shown below in Figure 19. During times of typical stages, the gage records stage at 12-hour increments, but during increases in stage, even well below the 14-feet monitor stage (yellow line), observation frequency picks up to as low as 3-minutes in this example. This leads to fairly irregular observation increments and irregular observation times. The 12-hour readings prior to the rise in stage occurred at 10:36:18 am/pm and then 10:37:18 am/pm after the peak. This varies significantly over the period of record.

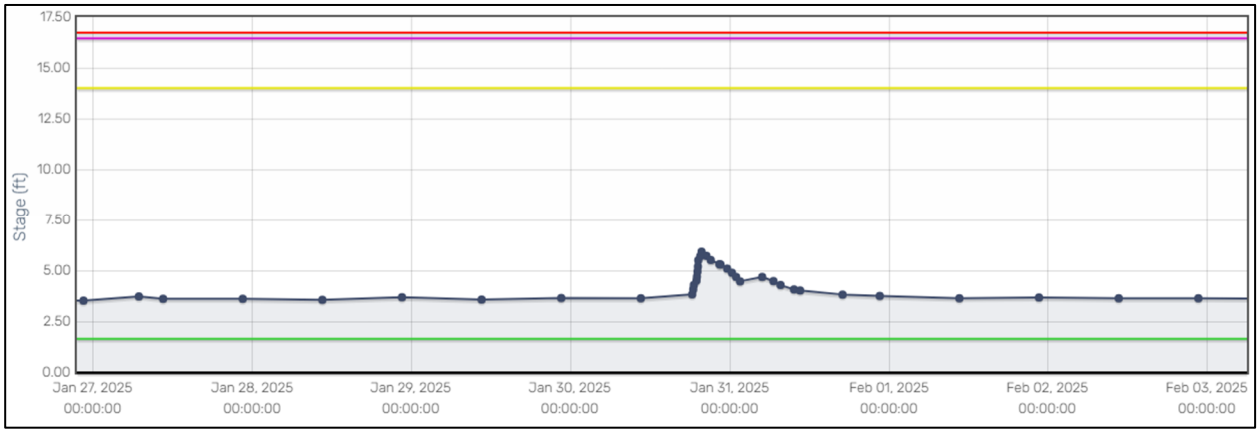

Figure 19. Example of irregular stage observation intervals at Johnson Dr. at Turkey Creek gage (SW TU04).

Period of record data previously analyzed and used for this SQRA included peak annual stage and flow data at the, now inactive, Turkey Creek at Kansas City, KS gage (USGS 06892940) from 1974 to 1987. Additionally, field measurements were taken from 1987 to 1989 at this gage. This gage is located approximately 4.7 river miles downstream of the project area.

Period of record data is also available at the Turkey Creek at Merriam, KS gage (USGS 06892800), including annual peak data from 1974 to 1986 and 2006 to current. There are also field measurements from 2003 to 2018. This gage location does not record daily or instantaneous data.

Period of record data is also available from the Turkey Creek at Mission, KS gage (USGS 06892900). This gage records stage only and only began instantaneous observations in August of 2022. Annual peak data is not published at this gage as of now. This gage is located about 2.5 river miles downstream of the project and is within the model extents.

Table 8. Systematic record of gage data for the levee system.

Gage	Daily Water Surface Elevation (ft-NAVD88)	Daily Discharge (cfs)	Peak Annual Elevation (ft-NAVD88) and Flow (cfs)	Field Measurements Elevation (ft-NAVD88) and Flow (cfs)	Instantaneous (15-min, hourly) Elevation (ft-NAVD88) and Flow (cfs)
Johnson Dr at Turkey Creek gage (Stormwatch TU04)[1]	N/A	N/A	N/A	N/A	1998-Current[2]

Gage	Daily Water Surface Elevation (ft-NAVD88)	Daily Discharge (cfs)	Peak Annual Elevation (ft-NAVD88) and Flow (cfs)	Field Measurements Elevation (ft-NAVD88) and Flow (cfs)	Instantaneous (15-min, hourly) Elevation (ft-NAVD88) and Flow (cfs)
Lamar Ave at Turkey Creek gage (Stormwatch TU04)[1]	N/A	N/A	N/A	N/A	1998-Current[2]
Turkey Creek at Merriam, KS (USGS 06892800)	N/A	N/A	1974-1986, 2006-Current	2003-2018	N/A
Turkey Creek at Mission, KS (USGS 06892900)[1]	N/A	N/A	N/A	Aug2022-Current	Aug2022-Current
Turkey Creek at Kansas City, KS (USGS 06892940)	N/A	N/A	1974-1987	1987-1989	N/A

[1]Stage gage only. No flow data is recorded
[2] Instantaneous data is irregular and inconsistent over the period of record

Record stages on Turkey Creek were produced prior to most StormWatch gages coming online and outside of the period of record of Turkey Creek USGS gages. It should be noted that the below list of historic data was used for developing a flow frequency curve as a check to the hydrology being used for design. Additionally, many of these flows are rough estimates from historic documentation or from RAS modeling. Some have had a basin area ratio applied to shift all historic flows to the Southwest Blvd gage location for the purposes of a semi-comprehensive input for Bulletin 17C. Floods that were described in documentation as having *minimal* ponding at State Line were given a best estimate flow of 9,000 cfs based on HEC-RAS rating curves developed during a previous Lower Turkey Creek study. Floods with *some* ponding at State Line were given a best estimate flow of 10,000 cfs.

Table 9. Historical data prior to systematic record.

[2]Flow estimated based on description of event.

4.2.2. Historic Floods

Major floods on Turkey Creek are usually caused by short-duration, high-intensity storms following an extended period of general rainfall over the basin. The rainfall preceding the heavy rains saturates the soil, preventing further infiltration and producing runoff into the Turkey Creek channel, creating higher than average flow. Since the Turkey Creek channel is so narrow and urbanized, it is usually subject to flash flood events, which are difficult to forecast and prepare for. Earlier flood events on Turkey Creek are known to have happened in 1844, 1935, 1944, 1958, 1961, and 1968. Little information was documented for these specific events. Recent flood events that have available records and documentation include 1977, 1993, 1995, 1996, 1998, and 2017. However, the focus will be on the four of the largest flood events, which were 1977, 1993, 1998, and 2017. The 1977, 1993, and 1998 floods' rainfall data were recorded by the same rain gage at Shawnee, Kansas. Precipitation for the 2017 events were determined using both Johnson County StormWatch rain gage data and National Weather Service (NWS) radar observations. A basin average is provided for 21–22 August 2017. Table 10 summarizes the observed precipitation events. Subsections 4.2.2.1 through 4.2.2.8 discuss details pertaining to historic flood events.

Table 10. Comparison of Rainfall Totals for Major Turkey Creek Floods

Flood Event Date	Peak Hour Rainfall (inches)	Total Rainfall (inches)	Recorded Dates
1977	1.60	10.90	12–13 September 1977
1993	1.50	6.00	10 July 1993
1998	3.51	5.61	04 October 1998
2017	1.05	5.71	21–22 August 2017

4.2.2.1. June 1935

The greatest known flood at Merriam, KS at the time occurred in June 1935 with an estimated Turkey Creek discharge of 13,650 cfs. It should be noted that a specific location of estimated flow was not given in the historic documentation, but it is assumed that flow was estimated at Johnson Dr. in Merriam, KS. This flood inundated the city area to depths of 7 feet above what was considered flood stage at the time. Development in the area was not extensive in 1935 and no estimated damage caused by this flood is available.

4.2.2.2. April 1944

The April 1944 flood at Merriam, KS had an estimated Turkey Creek discharge of 11,300 cfs. It inundated the city to depths of about 6 feet above what was considered flood stage at the time. 58 residences and businesses were affected, and the damage was estimated at $118,700 in 1944 price levels.

4.2.2.3. July 1958

In July 1958, a flood with an estimated discharge of 4,400 cfs inundated a total of 69 residences and business establishments and resulted in damages estimated at $155,000 in 1958 price levels.

4.2.2.4. September 1961

The September 1961 flood at Merriam had an estimated discharge of 4,700 cfs and inundated a total of 82 residences and business establishments. An exhaustive damage survey, conducted shortly after the flood, established a value of $257,000 (1961 price levels) in damages in the city, of which $240,000 occurred along the main stem of Turkey Creek. This survey included all flood damages within the corporate city limits. The previous flood damage estimates may have included a smaller area, but the primary reason for the increasing damage values is the rapid development of the flood plain at the time.

4.2.2.5. September 1977

Locally known as the Plaza Flood, this was a flash flood event that occurred 12–13 September 1977, throughout the Kansas City metropolitan area. It was caused by a high intensity storm following a long period of light rain. Approximately 16 inches of rain fell over the Kansas City, Missouri, area over the course of the event.

Most of the focus was on Brush Creek, which travels through the Plaza and discharges into the Blue River. During this event, there were 25 fatalities and 1,000 automobiles totaled, along with millions of dollars in damages to the commercial and residential areas surrounding Brush Creek.

In the Turkey Creek area, $8.1 million (1977 price levels) in damages occurred from flooding. Although damages were extensive, the urban study conducted after the flood determined implementing a program for managing flood events along Turkey Creek was not feasible.

4.2.2.6. July 1993

Extensive flooding occurred on 10 July 1993. Although this year was also a major flood year for the Missouri and Kansas Rivers in Kansas City, this was an unrelated flash flood event caused by high intensity storms on that date. When Turkey Creek flooded in 1993, it overtopped I-35 at five different locations. The flooding occurring during this event caused one fatality. Damages from the 1993 event were estimate at $3.4 million in Merriam, Kansas, and $20 million in the lower basin in 1993 price levels. A rainfall gage located at Overland Park City Hall (approximately 3.3 miles south of Merriam, Kansas) recorded the July 1993 storm event. Figure 20 provides a rainfall hyetograph of the event. According to this observed data, approximately 5.8 inches of rain fell over the upper portion of the Turkey Creek watershed within a 12-hour period.

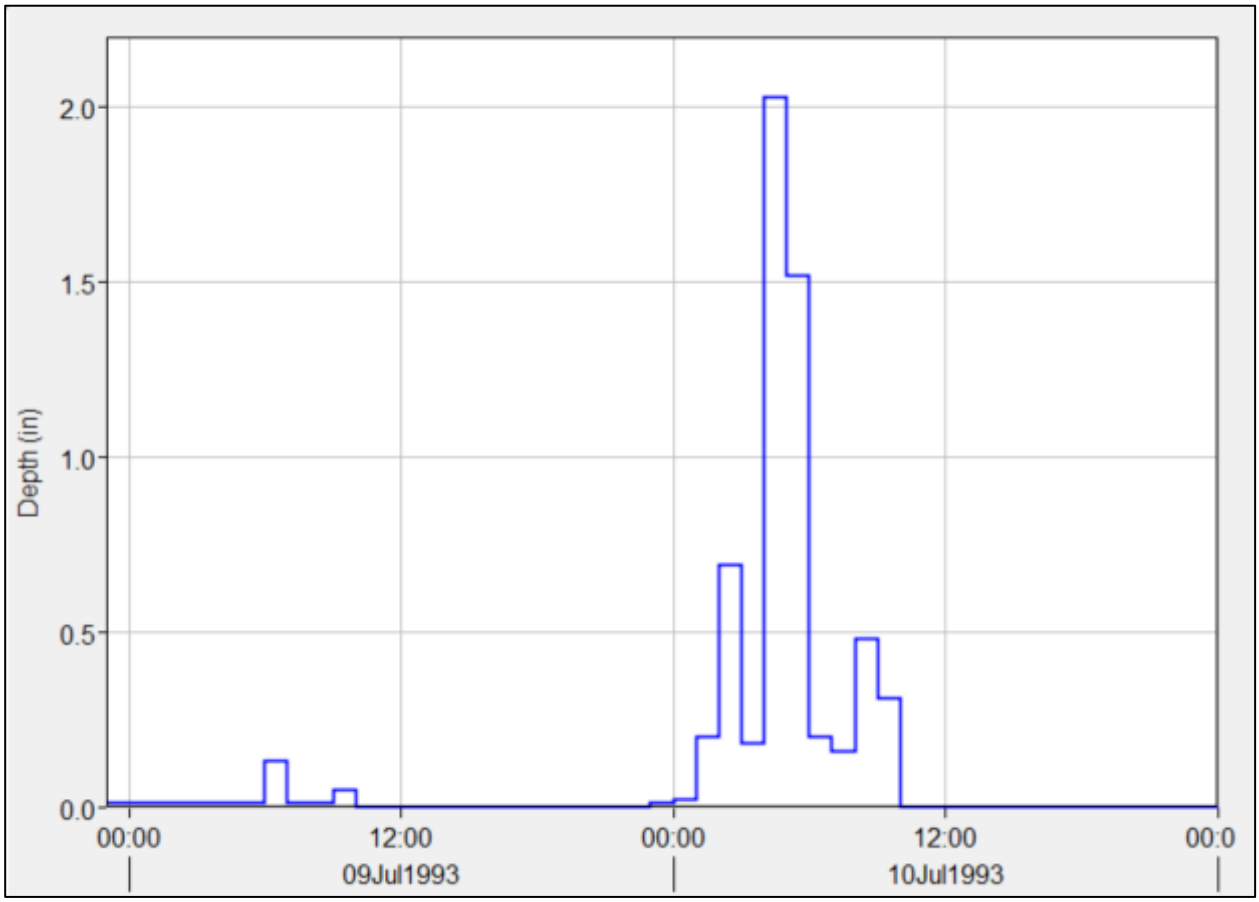

Figure 20. 10 July 1993 Rainfall hyetograph for Overland Park, Kansas City hall rain gage.

4.2.2.7. October 1998

The maximum flood of record for Turkey Creek occurred in October 1998 and resulted from the combined effects of saturated soil due to rain on 6 out of 7 days in one week and a high intensity storm that started 4 October 1998. The storm covered the Kansas City metropolitan area with rain for the entire day with afternoon rainfall totals of 0.25 to 1.00 inches. Around 7:00 p.m., another round of storms produced an additional 3 to 5 inches of rain in a 2-hour period. The rainfall produced by this event exceeded the rainfall amount defined as the 0.01 AEP (1/100-year event) at the time. Although this flood had the least amount of total rainfall when compared to the 1977 and 1993 floods, it produced the highest amount of rainfall in the peak hour. Figure 21 illustrates the 10 hours of highest rainfall intensity of the 1998 rainfall event hyetograph emphasizing the rapidness of this event. The worst damages caused by this flood occurred at Merriam, Kansas, near the midpoint of the Upper Turkey Creek reach. Multiple bridges and roadways were flooded during this event including I-35 and the BNSF railroad tracks south of 75th Street. The total cost of damages was estimated at $12 million in Merriam, Kansas, and $20 million in the lower basin area, in 1998 price levels.

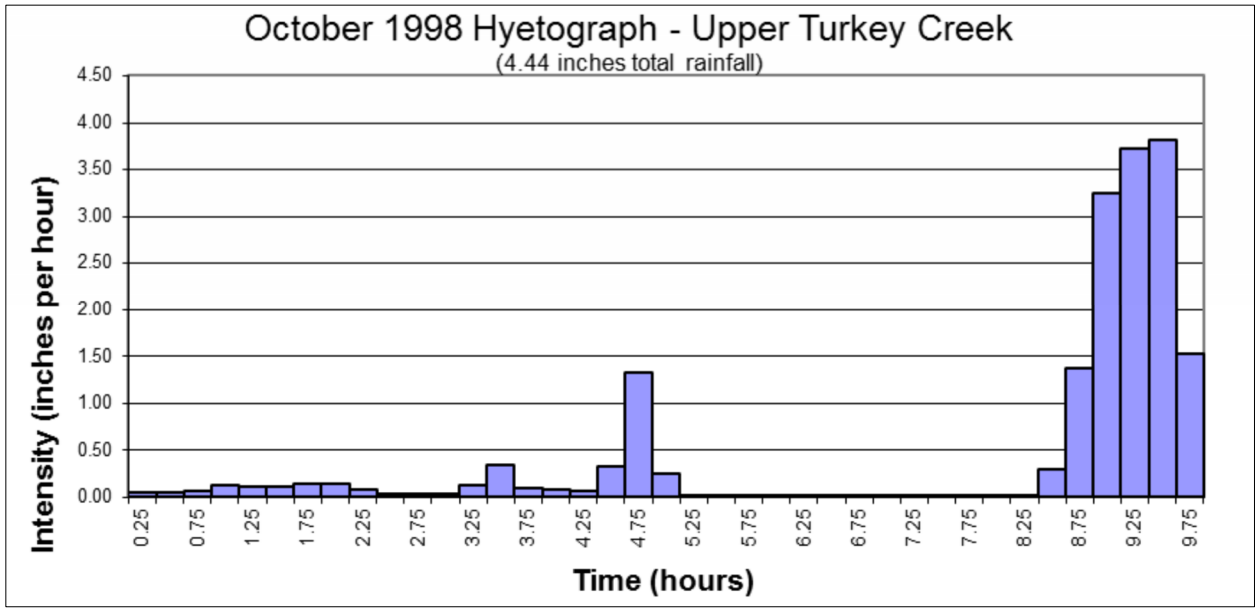

Figure 21. Hyetograph of 4 October 1998 Storm Event

4.2.2.8. 2017 Floods

Three significant rainfall events occurred in the Turkey Creek watershed during the summer of 2017 on 26–27 July, 5–6 August, and 21–22 August. Storm total precipitation was highest on 21–22 August, but the intensity was greater for 26–27 July and 5–6 August. Rainfall from the events produced some of the highest stages along Turkey Creek since the flood of record on 4 October 1998. Of the 2017 events, 26–27 July resulted in the record stage of 16.45 feet at the Johnson Drive gage.

Precipitation, flow rate, and stream stage from the 2017 events were compared to historical records and to published data. Precipitation totals for the 2017 events were determined using both Johnson County StormWatch rain gage data and NWS radar observations. The rain gages were located along Turkey Creek at Johnson Drive, Southwest Boulevard, and Lamar Avenue. Average basin precipitation totals

were estimated from the NWS radar data using the Meteorological Visualization Utility Engine (MetVUE) software.

26-27 July 2017 Flood

An average of 5.27 inches of rain fell over the Turkey Creek Basin between 12:00 p.m. on 26 July 2017, and 6:00 a.m. on 27 July 2017. Approximately 68 percent of this total fell in a three-hour period between 1:00 and 4:00 a.m. on the 27th; while the maximum hourly total was 1.52 inches, occurring between 2:00 and 3:00 p.m. on the 27th. Table 11 shows precipitation totals for the gages and the basin. All the rain gages recorded higher totals and more intense rainfall than the basin average. Figure 22 shows the basin average hyetograph.

Table 11. Precipitation totals for 26–27 July 2017.

Location	Total (inches)	Maximum 1-hour (inches)	Maximum 3-hour (inches)	Maximum 6-hour (inches)
Southwest Boulevard	5.92	1.80	4.12	5.32
Lamar Avenue	5.24	1.76	3.96	4.80
Johnson Drive	5.56	2.16	4.28	5.20
Basin Average	5.27	1.52	3.58	4.51

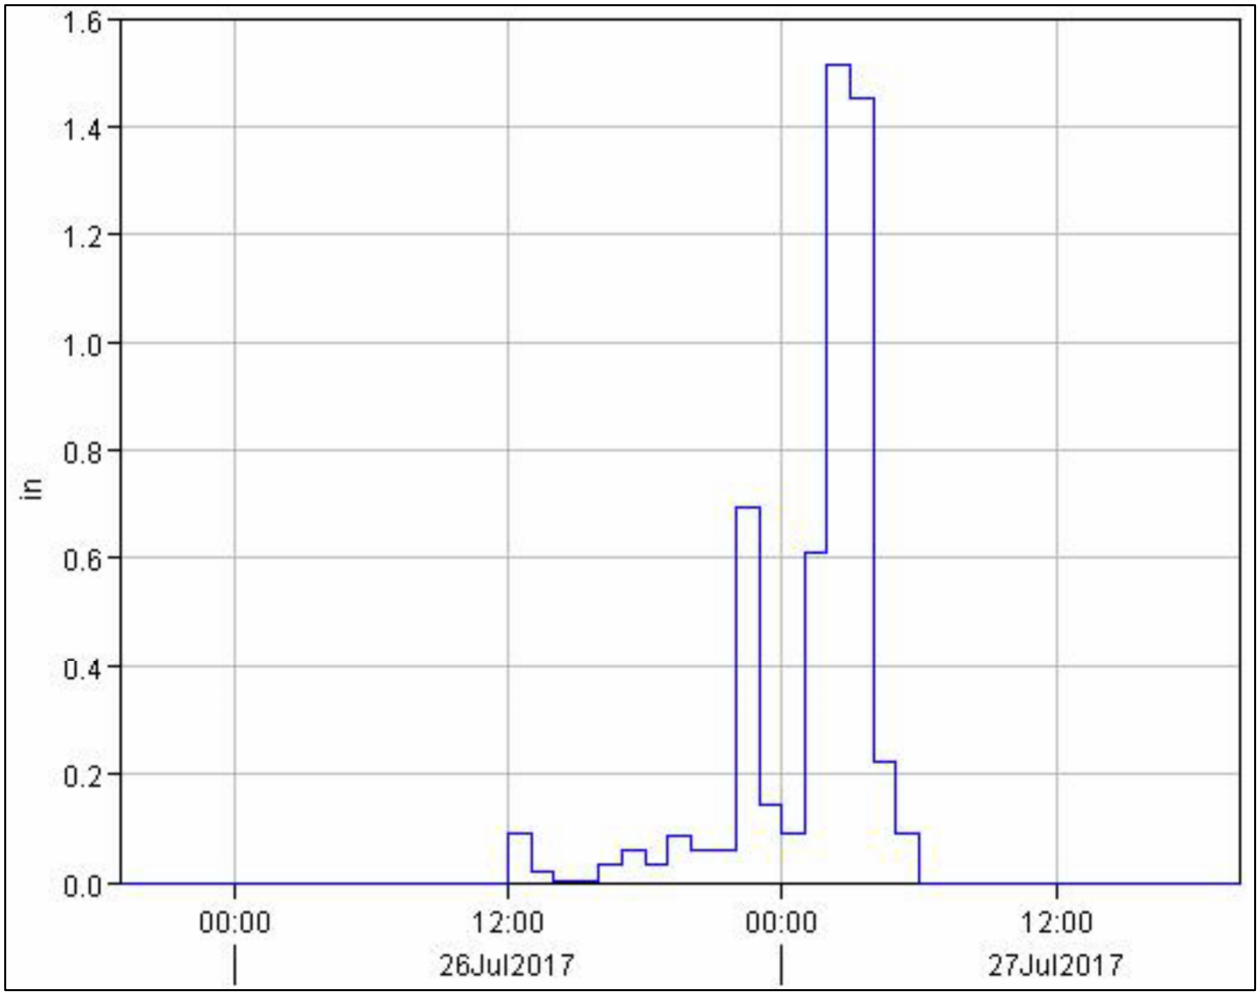

Figure 22. Turkey Creek Basin Average Hyetograph for 26–27 July 2017.

5-6 August 2017 Flood

A total of 4.75 inches of rain fell over the Turkey Creek Basin between 8:00 a.m. 5 August 2017, and 2:00 a.m. 6 August 2017. Approximately 75 percent of the total precipitation fell in a three-hour period between 8:00 p.m. and 11:00 p.m. on the 5th; while the maximum 1-hour intensity was 1.55 inches between 10:00 p.m. and 11:00 p.m. Table 12 shows storm precipitation totals for the gages and the entire basin. The rainfall totals were significantly higher at the Lamar Avenue and Johnson Drive gages than the basin average and the Southwest Boulevard gage. Peak discharge was estimated using the USACE lower Turkey Creek design model at Johnson Drive and Southwest Boulevard in the Turkey Creek 2017 flood report. Figure 23 shows the basin average hyetograph.

Table 12. Precipitation totals for 5–6 August 2017.

Location	Total (inches)	Maximum 1-hour (inches)	Maximum 3-hour (inches)	Maximum 6-hour (inches)
Southwest Boulevard	4.72	1.48	3.64	4.04
Lamar Avenue	6.32	2.24	4.48	5.20
Johnson Drive	6.12	2.68	5.20	5.40
Basin Average	4.75	1.55	3.58	3.89

*Note: Peak discharges estimated using RAS rating curves from lower Turkey Creek design model

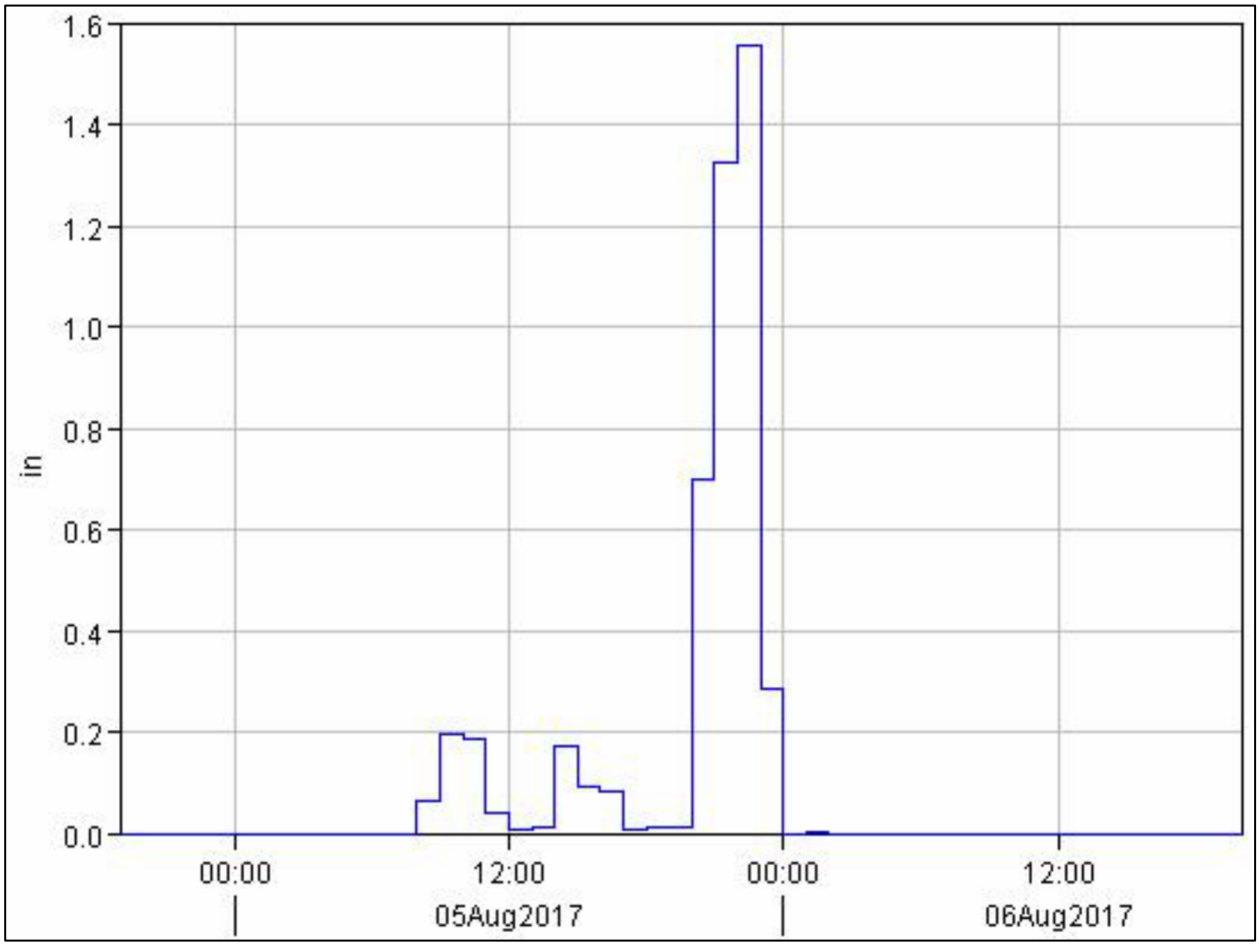

Figure 23. Turkey Creek Basin Average Hyetograph for 5–6 August 2017

21-22 August 2017 Flood

The total basin precipitation for 21–22 August 2017, was 5.71 inches, and occurred between 8:00 a.m. on the 21st and 6:00 a.m. on the 22nd. The maximum hourly total was 1.05 inches between 2:00 and 3:00 a.m. on the 21st, and the maximum three-hour total was 2.76 inches between 1:00 and 4:00 a.m. on the 21st. Table 13 contains the gage and basin rainfall totals for the event and indicates that the Southwest Boulevard gage recorded the greatest amounts. Figure 24 shows the hyetograph for the basin.

Table 13. Precipitation totals for 21–22 August 2017.

Location	Total (inches)	Maximum 1-hour (inches)	Maximum 3-hour (inches)	Maximum 6-hour (inches)
Southwest Boulevard	6.24	1.40	3.16	5.32
Lamar Avenue	5.24	1.08	2.72	4.64
Johnson Drive	4.96	1.08	2.84	4.56
Basin Average	5.71	1.05	2.76	4.60

4.2.3. Historic Trends and Ratings

The USGS has a published rating curve (https://waterwatch.usgs.gov/?id=mkrc), which relates the discharge to a water surface elevation (converted to "stage" at the gage). The rating curve is based on recent field measurements of water surface elevation and discharge and is typically "shifted" over time to better reflect the more recent data compared to older measurements. These shifts in the rating curve can be from a better understanding of the uncertainty of the field measurement data or could be an indication of geomorphologic changes to the river. Figure 25 shows the published USGS rating curve at Turkey Creek at Mission, KS (USGS 06892900). This gage has only been active since late 2022, so there has been little data of high magnitude events (field measurements) to develop the rating curve beyond the lower portion.

It should be noted that the USGS rating notes a stage of 3.43 feet as the 0 cfs flow, which corresponds to an elevation of 840.43 feet-NAVD88. This elevation differs significantly from the LiDAR channel bottom in the RAS model, which was determined to be 828.81 feet-NAVD88. LiDAR channel bottom is nearly 12 feet lower than the USGS rating curve zero flow stage which prevents the usability of this rating curve for calibration or validation purposes. The difference is illustrated below in Figure 26.

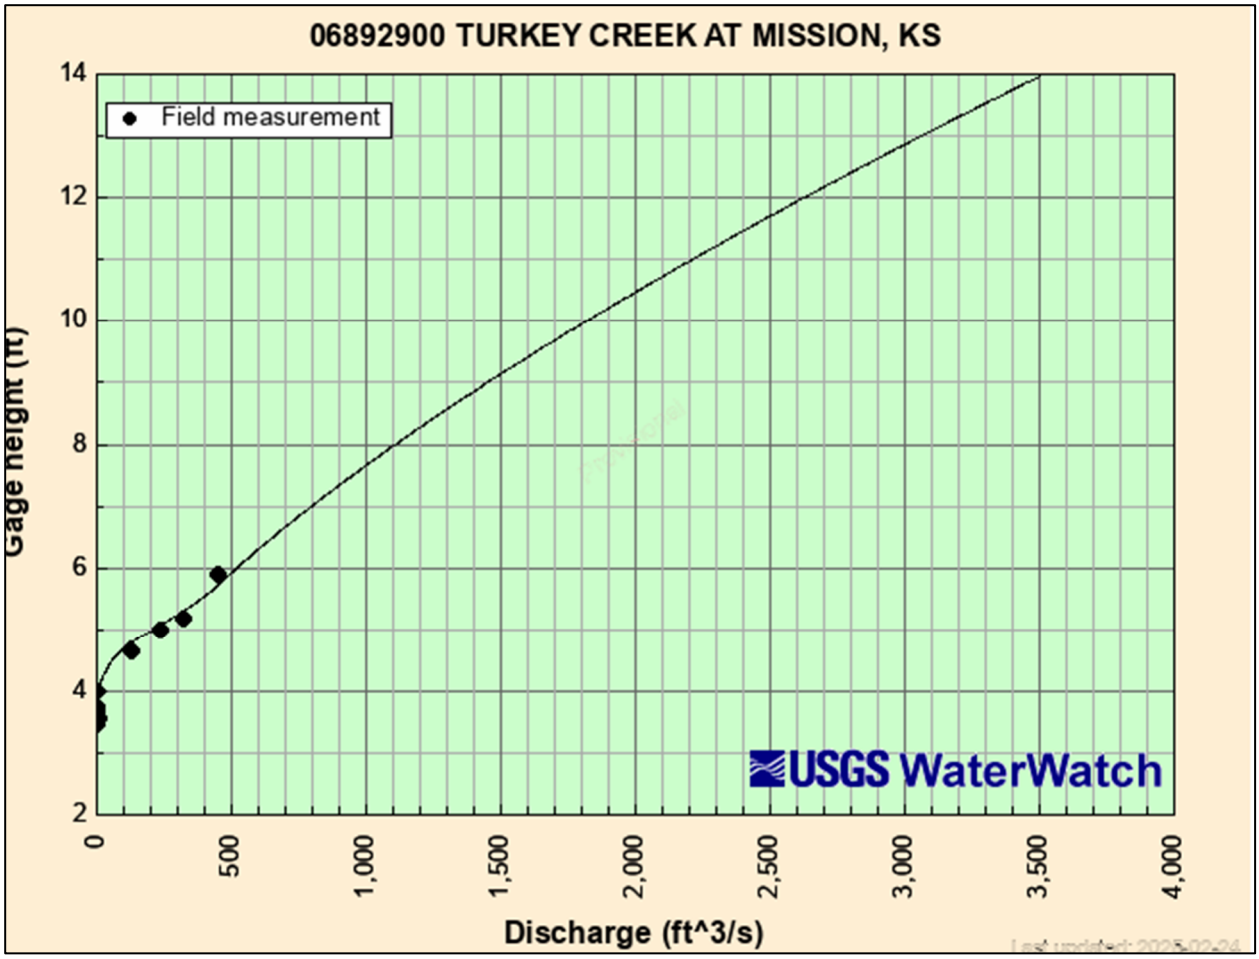

Figure 25. USGS discharge rating curve (zero gage height = 837.0 ft-NAVD88).

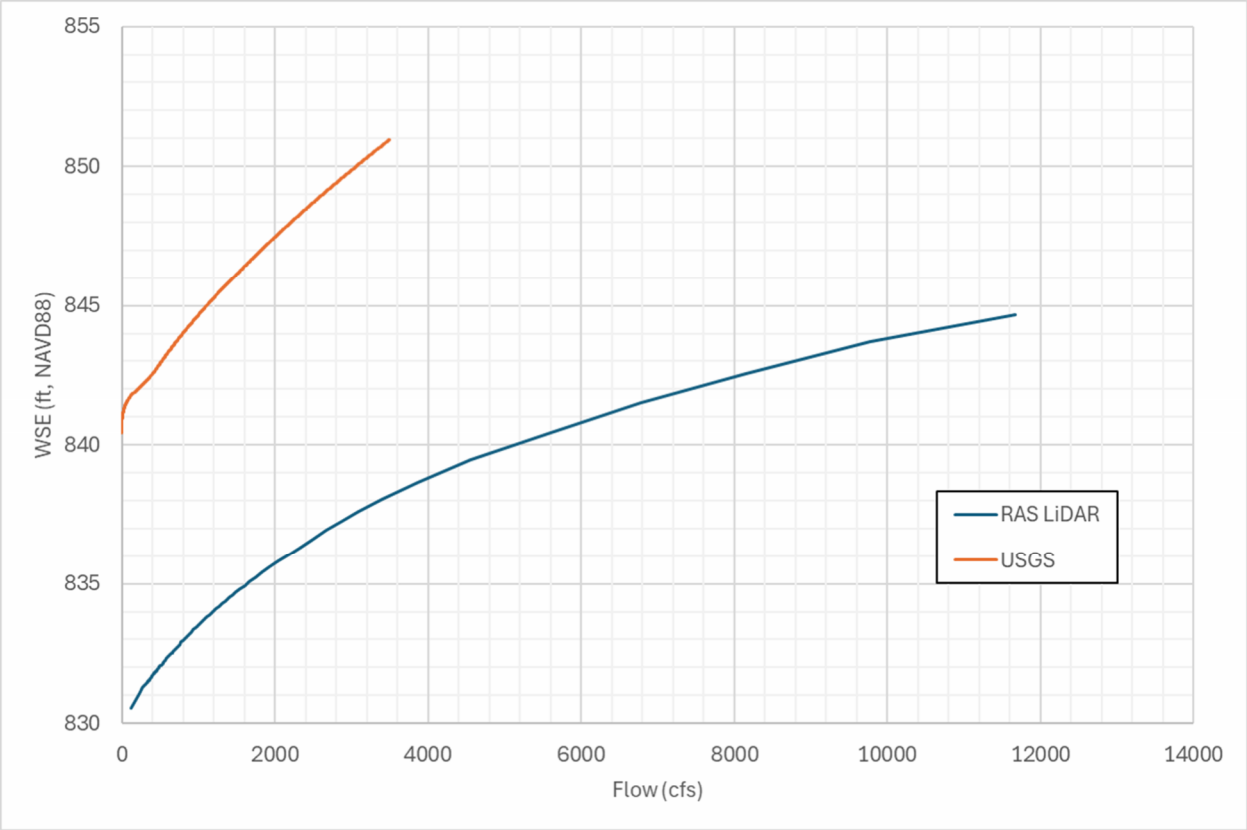

Figure 26. Comparison of USGS rating curve and HEC-RAS computed rating curve

4.2.4. Hydraulic Model Calibration/Validation

A fully two-dimensional rain-on-grid HEC-RAS hydraulic model was provided by Stantec which was developed in part to become the updated FEMA model for Johnson County, which was then modified to run 2D channel hydraulics instead of rain-on-grid for flood protection design (this model is referred to herein as the FEMA model). The FEMA model was previously calibrated with the August 22, 2017 and May 28, 2020 events and the July 2017 event was used for validation. It should be noted that calibration and validation of the FEMA model was completed using gridded precipitation of these historic events. There is not observed gage flow to serve as model inflows nor as calibration points. USACE found general uncertainty in the efficacy of channel and floodplain calibration of this model due to the use of rain-on-grid in such an urban area and a lack of stormwater modeling which significantly impacts routing times and volume accumulation. For this reason and to account for uncertainty, Manning's n-values for the channel were increased from 0.025 to 0.035 to account for any potential for underestimation of stages during levee profile design. The channel has seen sediment deposition over the last decade, so these changes were deemed appropriate.

Additionally, Manning's n-values meant to represent buildings were initially set to 1.0 in the model. This is typically only appropriate if cells with a 1.0 roughness value are exactly encompassing the building footprint. Otherwise, the large 1.0 value significantly skews the roughness where flow should be able to actively convey. In these situations, the HEC-RAS user's manual recommends setting the roughness values of buildings in the 2D mesh to 0.5. Since cells were not specifically configured to represent only

the building footprints, the building roughness value was changed to 0.5. Cell alignments within the channel and around critical areas were improved.

The model is not able to be calibrated in a non-rain-on-grid configuration due to the previously mentioned lack of observed flow data. This represents a major uncertainty in the hydraulics. HEC-RAS best practices were considered, and geometries were developed in such a way to lean towards conservatism given the lack of calibration data.

4.3. Hydrology

4.3.1. Peak Annual Discharge-Frequency

Hydrology was previously determined during the Upper Turkey Creek feasibility study phase and is being used for design. Flows were developed by taking Atlas 14 frequency precipitation depths and computing rainfall runoff to known inflow locations along Turkey Creek using an existing hydrologic model. HEC-1 was originally used during a 2005 Johnson County watershed study with TP40 precipitation and then was updated with Atlas 14 values during the feasibility study in 2015. Table 14 below details the frequency flows obtained by routing the Atlas 14 rainfall runoff in HEC-RAS at Johnson Drive bridge.

Table 14. Hydrology used for design.

AEP (1/year)	Peak flow at Johnson Drive (cfs)
0.002 (1/500yr)	22700
0.005 (1/200yr)	19900
0.01 (1/100yr)	17500
0.02 (1/50yr)	15600
0.05 (1/20yr)	13500
0.10 (1/10yr)	10500
0.20 (1/5yr)	8800
0.50 (1/2yr)	6800

During preliminary design, a Bulletin 17C analysis was conducted in HEC-SSP to check the validity of these results. Any available previous annual peak flow data from inactive USGS gages were taken and basin area adjusted to Turkey Creek at Kansas City, KS gage (USGS 06892940) along with best estimate flows for documented flood events as previously discussed in Section 4.2.1. Peak annual discharges from 1974 to 1987 and 1998 to 2023 were imported into HEC-SSP version 2.3. Discharge-frequency curves were developed for the observed period of record, with the addition of historical flows, and perception thresholds based on flood documentation. Regional skew values were not used in the Bulletin 17C analysis because they produced significantly lower flows for the 1% thru 0.2% AEP events. Generally regional skew values for Kansas and Missouri do not perform well in the urban Kansas City metro area. Table 15 provides the discharge-frequency statistics generated by HEC-SSP using the compiled record with historic data. Figure 27 provides the peak annual flow record for the Bulletin 17C analysis.

Table 15. Discharge-frequency statistics.

Statistic	Peak
Mean	3.710
Standard Deviation	0.200
Computed (Station) Skew	0.683
Regional Skew (Peak Flow)	N/A
EMA estimate of Mean Square Error (MSE)	0.165
Weighted Skew	N/A
Effective Record	94

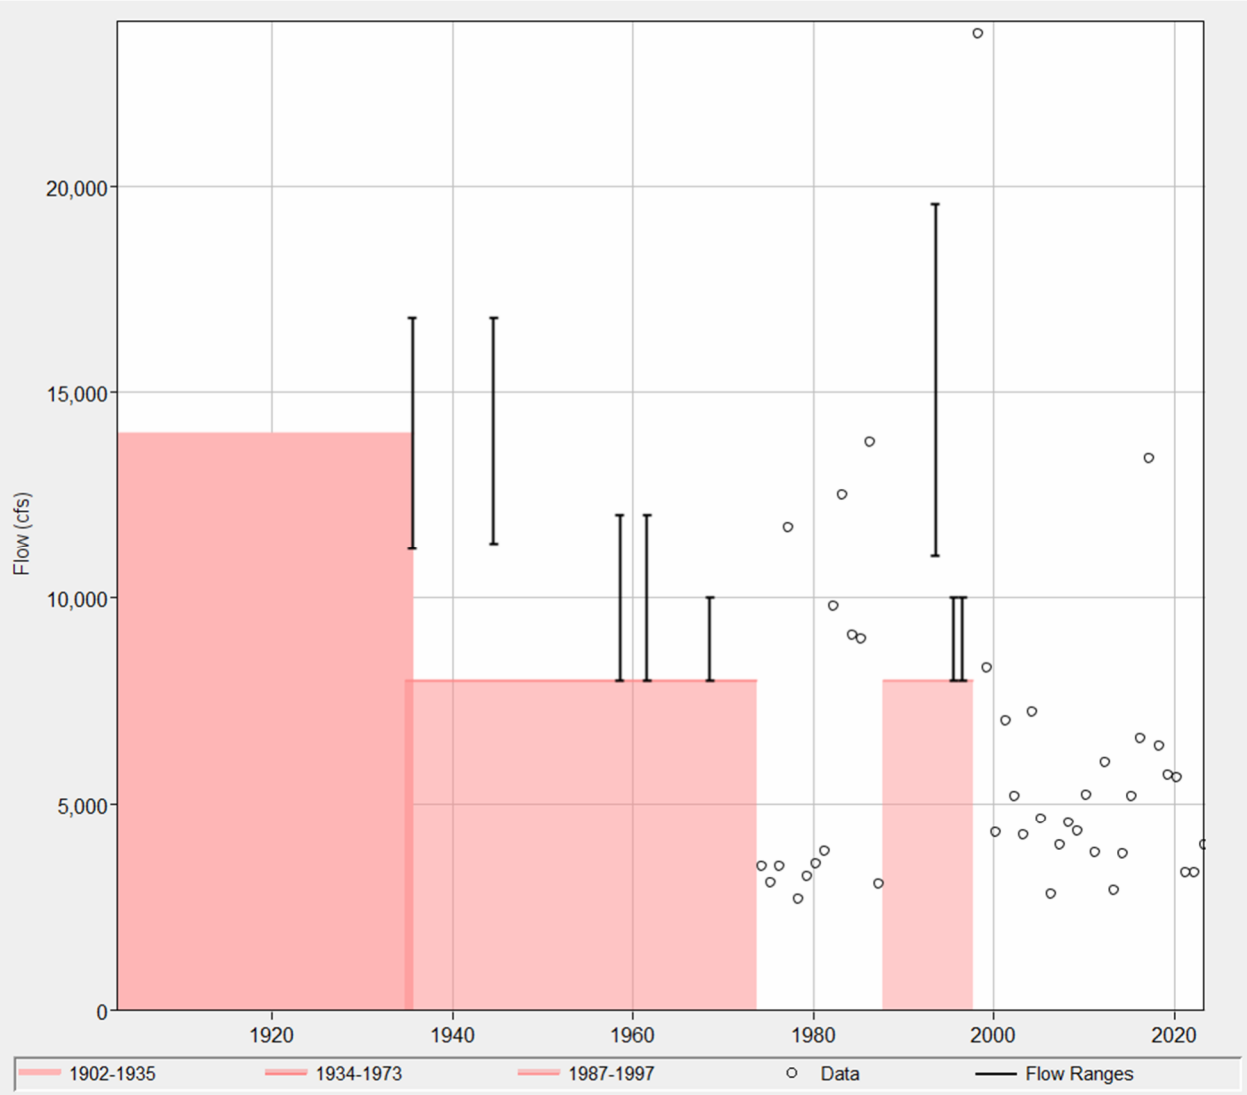

Figure 27. Bulletin 17C analysis: Peak annual flow record.

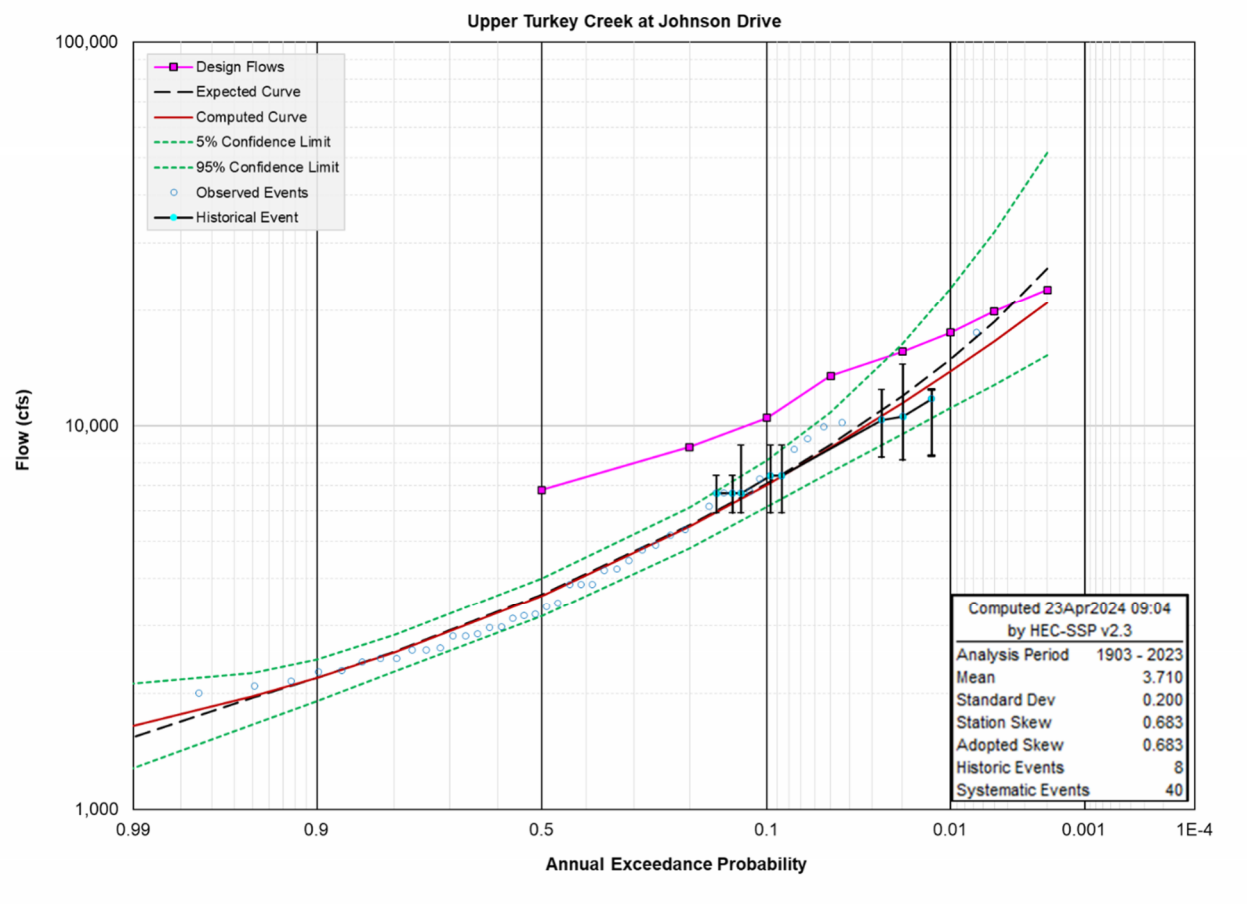

Figure 28. Bulletin 17C analysis: Peak discharge-frequency curves.

The discharge frequency curve was translated upstream to Johnson drive using an average regression ratio of 0.74. This ratio was developed by taking an average of the USGS 2017 regression equation (SIR 2017-5063) results between sites for each frequency. Table 16 below provides those computed results and a comparison to the HEC-1 routed frequency flows. The peak flows from routing the HEC-1 inflows through HEC-RAS trend higher than the Bulletin 17C analysis. These values fall within the confidence limits for the 0.02 AEP through 0.002 AEP flows. The more frequent discharges exceed the 0.05 confidence limit from the Bulletin 17C analysis. Less weight was given to these more frequent discharges given that they are outside of any magnitude of flow used for consequence modeling. The adopted design frequency of 0.01 AEP is within the confidence bounds of the Bulletin 17C curve but plots higher than the expected curve. Due to the lack of consistent observed annual peak flow data, and the resulting uncertainty in the flow frequencies, it was deemed reasonable to use the higher Atlas 14 HEC-1 computed inflows for design.

Table 16. Comparison of design hydrology to Bulletin 17C analysis.

AEP (1/year)	HEC-1 Peak Flow (cfs)	B17C Expected Flow (cfs)	Confidence Limits Flow (cfs)	
			0.05	0.95
0.002 (1/500yr)	22700	25800	51500	15300
0.005 (1/200yr)	19900	18700	32200	12800
0.01 (1/100yr)	17500	14900	22800	11100
0.02 (1/50yr)	15600	11900	16400	9520
0.05 (1/20yr)	13500	8900	10900	7570
0.10 (1/10yr)	10500	7100	8140	6170
0.20 (1/5yr)	8800	5500	6140	4800
0.50 (1/2yr)	6800	3600	4000	3180

4.3.2. Stage-Duration Curves

Annual stage-duration curves were developed using HEC-SSP at the Johnson Drive at Turkey Creek (StormWatch TU04) gage, which is located within the project extents. It should be noted that the period of record for the Stormwatch gage TU04 goes back to 1998 but observed stage data prior to 2014 was very inconsistent, including large shifts in average low flow stages for months at a time before suddenly shifting upwards or downwards. Additionally, there were numerous erroneous spikes in the stage data well beyond the record flood stage during smaller events. For this reason, only data from 2014 and onwards was used to develop the stage-duration curve. The stage-duration curve for Johnson Drive is shown in Figure 29.

Because the levee/floodwall does not experience a water surface elevation of 1 foot or higher above the elevation of the landside levee or floodwall toe at least once a day for more than 36 days (10 percent of the time) per year on average, it is considered infrequently loaded according to ER 1110-2-1806.

A stage-duration curve was also computed further downstream using the Lamar Avenue at Turkey Creek (StormWatch TU08) gage to approximately represent the downstream boundary of the hydraulic model. Similar to the Johnson Drive gage, the pre-2014 data was quite inconsistent and was not used in the analysis. There is no levee system at this location and so an approximate channel capacity stage was shown instead for Figure 30.

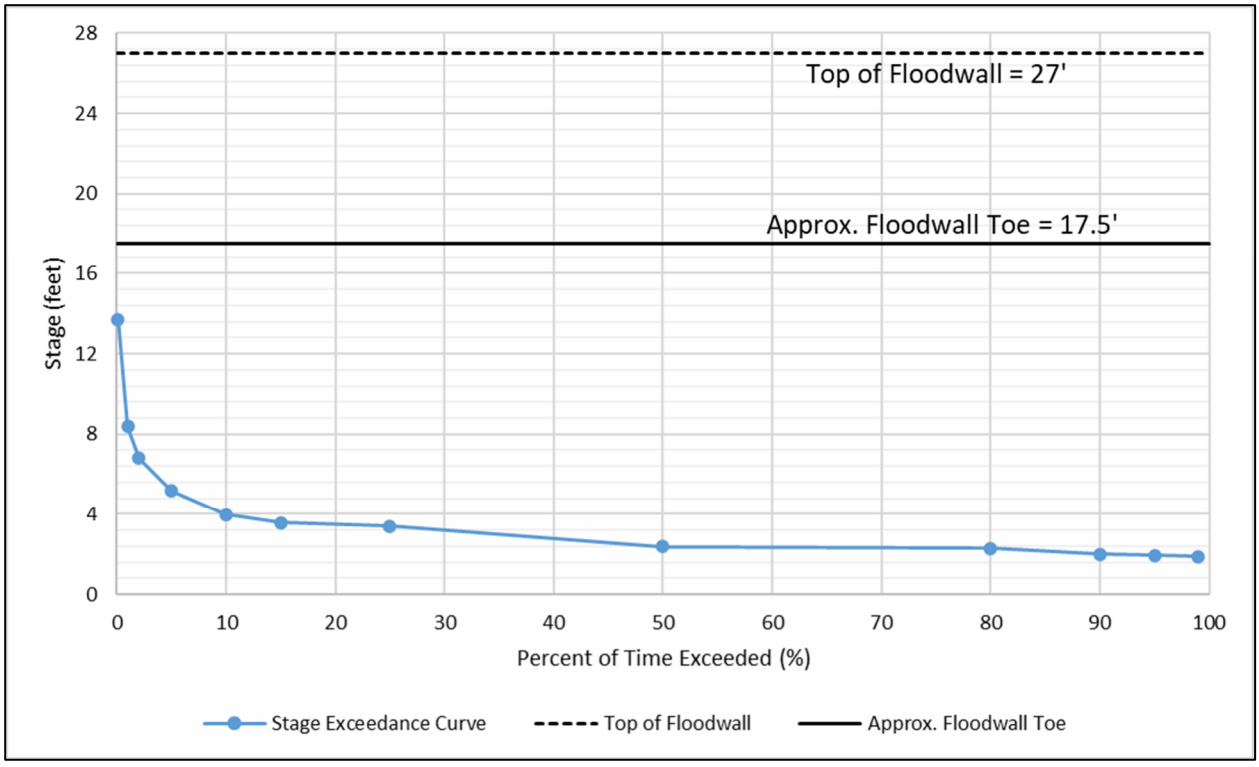

Figure 29. Stage-duration curve at Johnson Drive at Turkey Creek gage (StormWatch TU04).

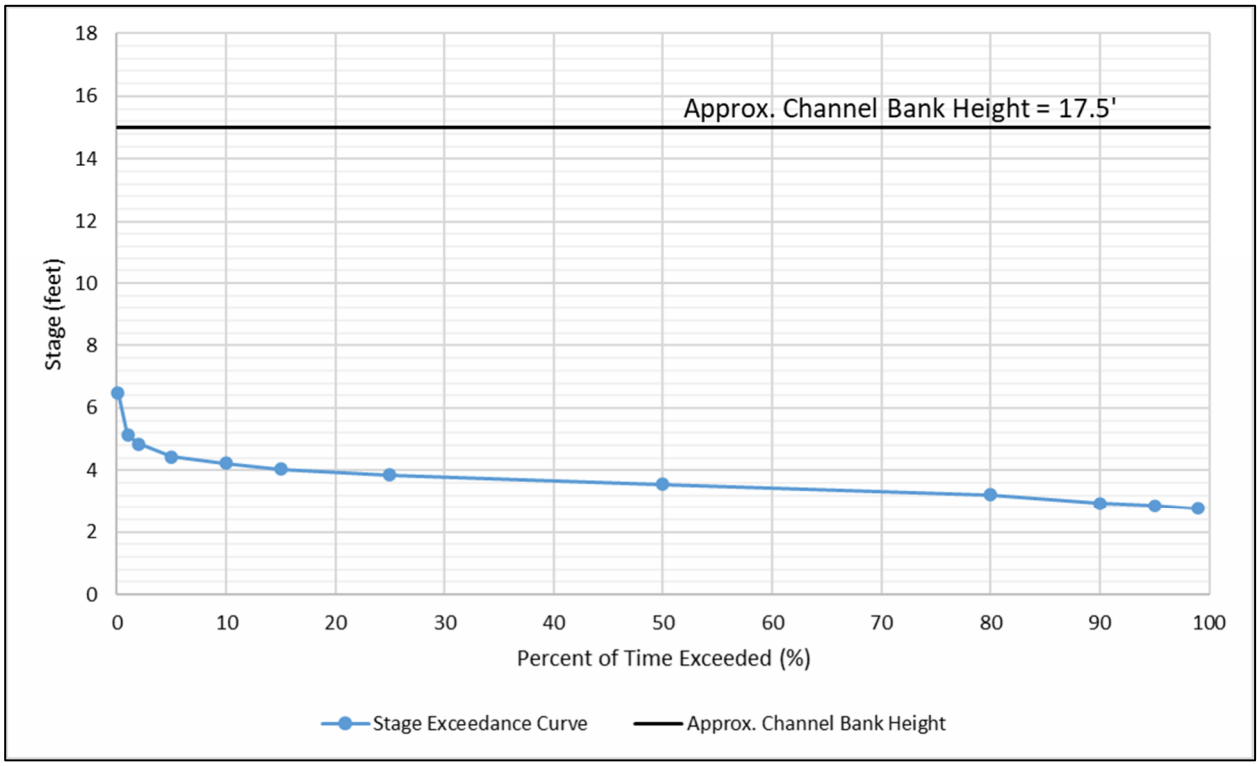

Figure 30. Stage-duration curve at Lamar Avenue at Turkey Creek gage (StormWatch TU08).

4.3.3. Volume-Frequency

Volume-frequency analysis for durations beyond the peak discharge frequency was not performed. Turkey Creek is characterized as a flashy system and flood events are typically less than 1 day in duration. Additionally observed daily or sub-daily flow data is not available.

4.3.4. Expected Flood Durations

Figure 31 provides the synthetic frequency hydrographs used for the SQRA analysis as well as the observed July 2017 stage hydrograph at the Johnson Drive StormWatch gage. The July 2017 flood event is the flood stage of record in the Johnson Drive gage record. The 2017 flood exceeded the banks at this location but not the toe height. The 0.002 AEP (1/500 year) hydrograph overtops the levee slightly in this location. More significant overtopping occurs at other locations of the levee system for this frequency event.

It should be noted the expected flood durations for both the synthetic and observed events are very short. As seen in the figure, these hydrographs exceed the banks and then recede back below the bank in 2-6 hours depending on the flood magnitude. Flood events on Turkey Creek are very short lived even with extreme cases such as the 0.002 AEP (1/500 year) hydrograph.

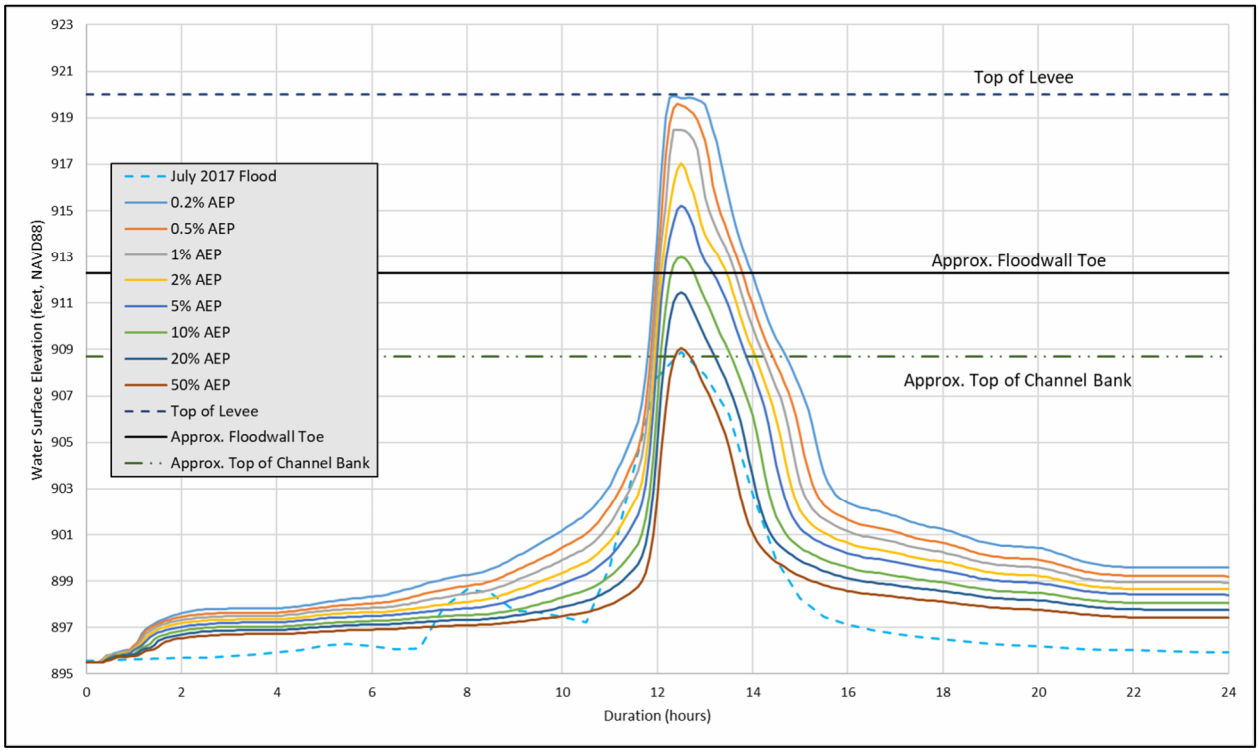

Figure 31. Synthetic flood hydrographs with July 2017 flood hydrograph.

4.4. Hydraulics

4.4.1. Boundary Conditions

The HEC-RAS hydraulic model was carried forward with modifications that were discussed. This includes the truncation of the upper portion of the model to switch from rain-on-grid to flow hydrograph boundary conditions. The downstream boundary was set to normal depth, using the approximate bed slope of 0.00561 at that location. Figure 32 provides a schematic of the hydraulic model. Numerous local inflow hydrographs were set according to the HEC-1 hydrologic output locations along Turkey Creek to better represent natural channel inflows. Figure 33 details all inflow locations. More detailed information on the model setup and parameter selection can be found in the 35% DDR.

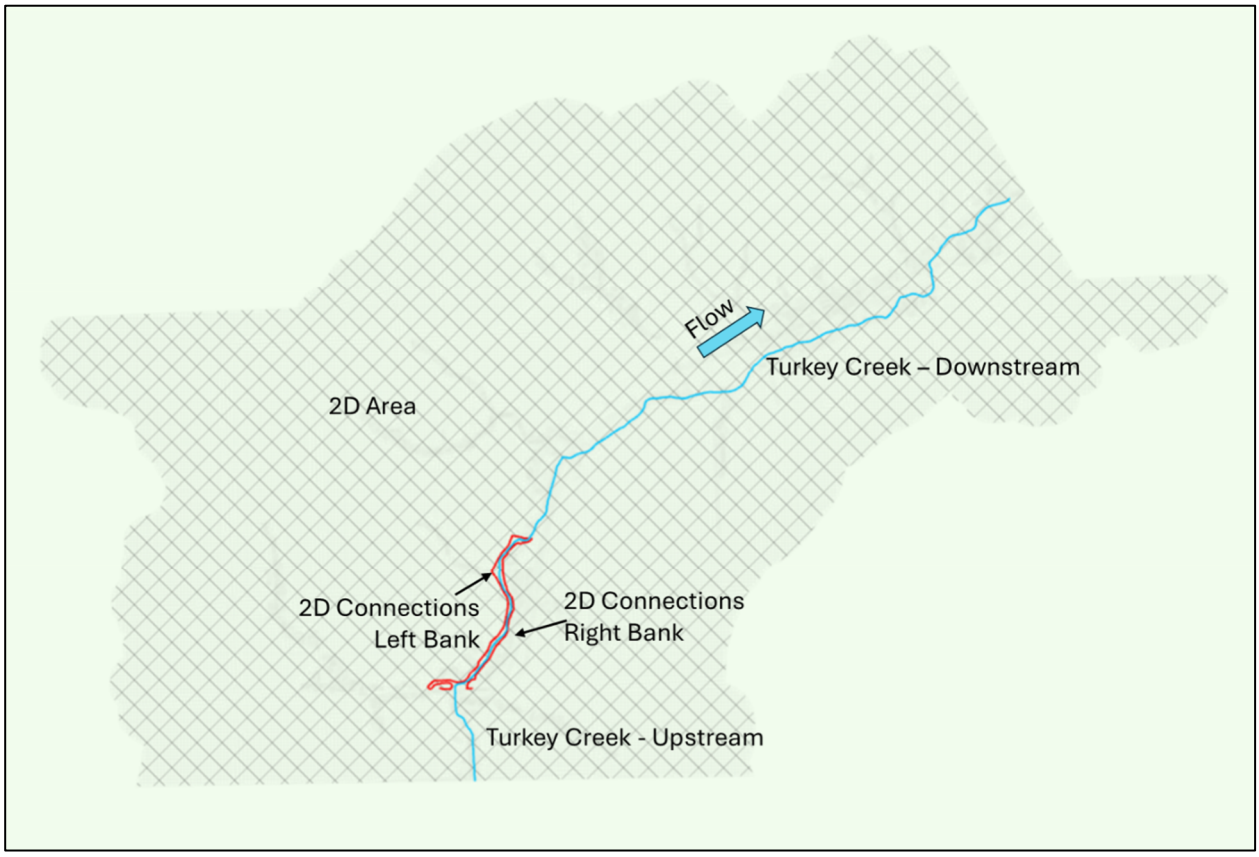

Figure 32. Hydraulic model schematic.

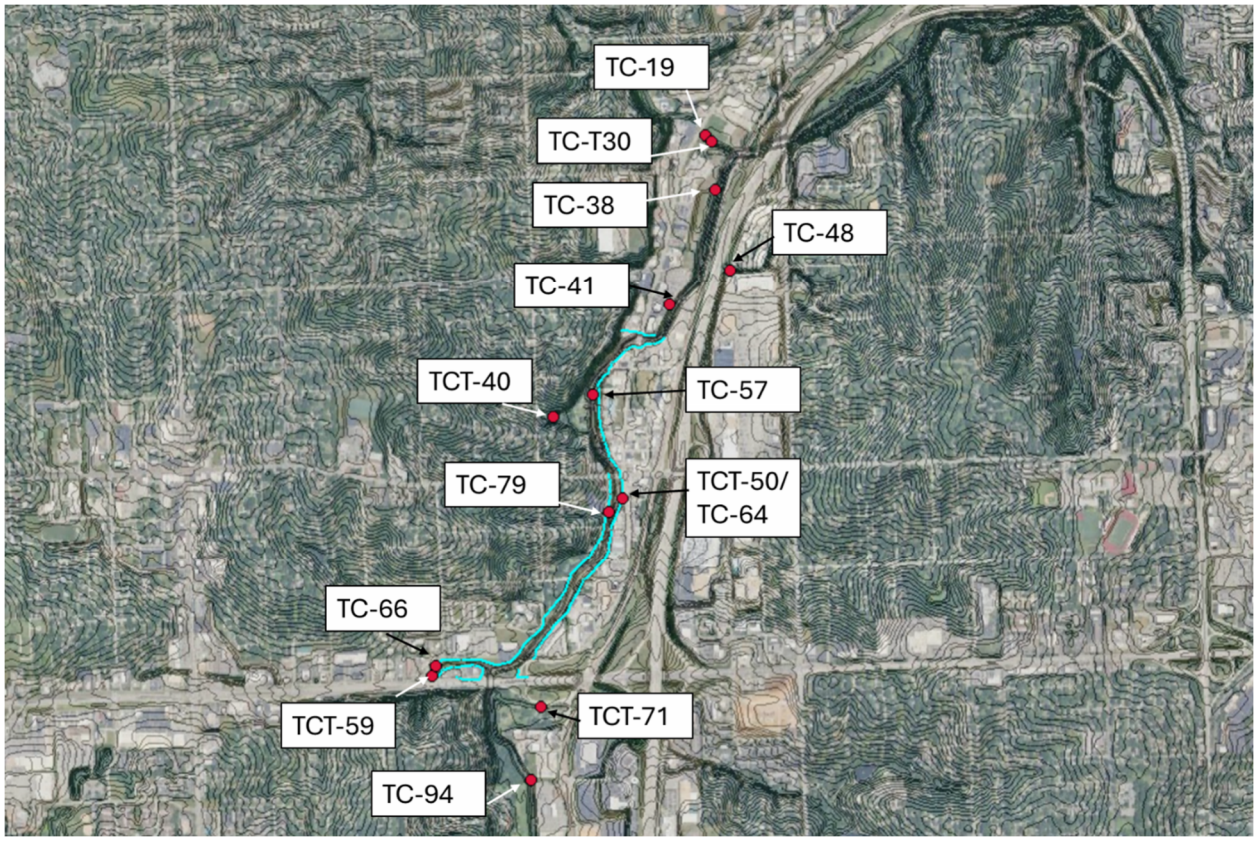

Figure 33. Flow hydrograph boundary condition locations.

4.4.2. Coincident Frequency Analysis

Water surface elevations along the levee system can theoretically be influenced by flood flows coming from a portion of Turkey Creek upstream of the project and/or the tributary at the start of the levee alignment. Given the very small drainage area of this watershed, there is not a case where the upstream Turkey Creek drainage area would experience extreme flooding and the tributary drainage area does not, or vice versa. Therefore, a coincident frequency analysis was not performed.

4.4.3. Flow Factoring

Frequency flows were routed through the HEC-RAS model using the synthetic design frequency flows. Historic flow hydrographs were not available given the lack of any sub-daily observed flow at any of the Turkey Creek gages. Frequency hydrographs are generally preferred because historic inflow hydrographs can get notably distorted when flow factor magnitudes get larger for very infrequent events such as the 0.002 AEP flow. This also assumes that the synthetic hydrographs are representative of typical flood durations experienced in the project area, which has shown to be the case previously in Section 4.3.4. These synthetic hydrographs allow for use of less extreme inflow factoring and prevent distortion of hydrograph shapes. All inflow hydrographs were factored uniformly to better represent larger storm

events, leading to larger local inflows within the project extents. Table 17 provides a summary of the frequency events and flow factors used for each loading scenario.

Table 17. Flow factoring for loading scenarios.

Loading Scenario	Elev at LCL	Base Flow Frequency	Flow Ratio
50%	909.03	100yr	0.904
75%	909.6	100yr	0.956
Top of Levee	910.1	200yr	0.908
0.5 ft OT	910.6	200yr	0.958
1.0 ft OT	911.1	500yr	1
2.0 ft OT	912.1	500yr	1.155

4.4.4. Levee Control Location

The levee control location (LCL) was identified at channel station 65+40 or right bank station 56+63 as shown in Figure 34. It should be noted that while this is the location of incipient overtopping, numerous other portions of the left and right bank systems begin overtopping within 5 to 10 minutes after. The current iteration of the levee profile design behaves as balanced overtopping. Levee superiority will be considered as design progresses to ensure overtopping does not occur in the upstream portions of the levee and lead to increases in consequences.

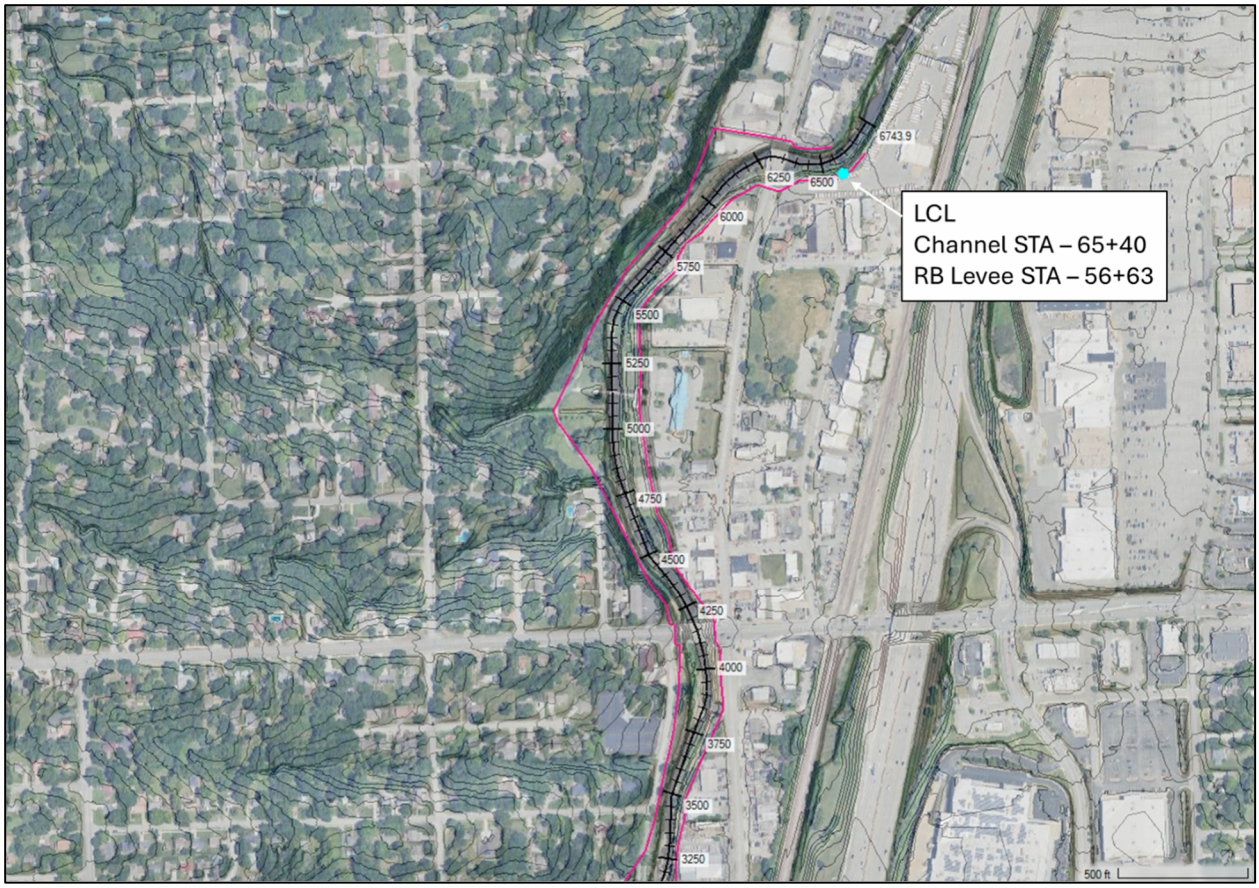

Figure 34. Location of incipient overtopping

4.4.5. Stage-Frequency Curves

Stage-discharge-uncertainty was estimated in accordance with EM 1110-2-1619 (USACE 1996) by performing a sensitivity analysis with Manning's n-values where upper limit and lower limit scenarios were modeled. The standard deviation was estimated by taking the mean stage difference between these estimates and dividing the difference by four. When compared to Table 5-2 in EM 1110-2-1619, the standard deviations were found to be lower than the fair and poor manning's n reliability classifications of 0.7 and 1.3, respectively. There is higher confidence in the quality of terrain data and manning's n values were set to be slightly higher than expected to account for uncertainty in design due to lack of calibration and validation. For this reason, the computed standard deviations were kept for development of the stage-frequency curve.

Table 18 summarizes the stage-discharge-uncertainty, which is also graphically portrayed in Figure 35. The stage uncertainty generally decreases as flow increases due to changes in hydraulic conditions. Conveyance area increases as stage increases and so the same flow increases produce smaller changes in water surface, thereby resulting in less sensitivity to manning's n variance. This effect is much more pronounced once overtopping occurs and flow conveyance area expands to the full floodplain width. Future analysis and design will perform sensitivity testing with stage uncertainty and evaluating its effect on levee height. It will be determined whether using larger stage uncertainties is appropriate for design, moving forward.

Table 18. Summary of standard deviation in stage uncertainty.

AEP Range	Flow Range (cfs)	Standard Deviation for Stage Uncertainty (ft), Index Location A
1-0.5	0 to 6,800	0.5
0.5-0.2	6,800 to 9,200	0.411
0.2-0.1	9,200 to 11,000	0.358
0.1-0.05	11,000 to 14,300	0.378
0.05-0.02	14,300 to 16,600	0.365
0.02-0.01	16,600 to 18,600	0.356
0.01-0.005	18,600 to 18,900	0.301
<0.005	>18,900	0.136

To prevent flatlining of the stage-frequency curve, the RAS rating curve at the LCL was linearly extrapolated out beyond the 1E-04 frequency as shown in Figure 35 to a flow and elevation of 40,000 cfs and 915.5 feet, respectively. Water surface elevations were extracted from the modeling results using a reference point at a 2D channel cell nearest the LCL.

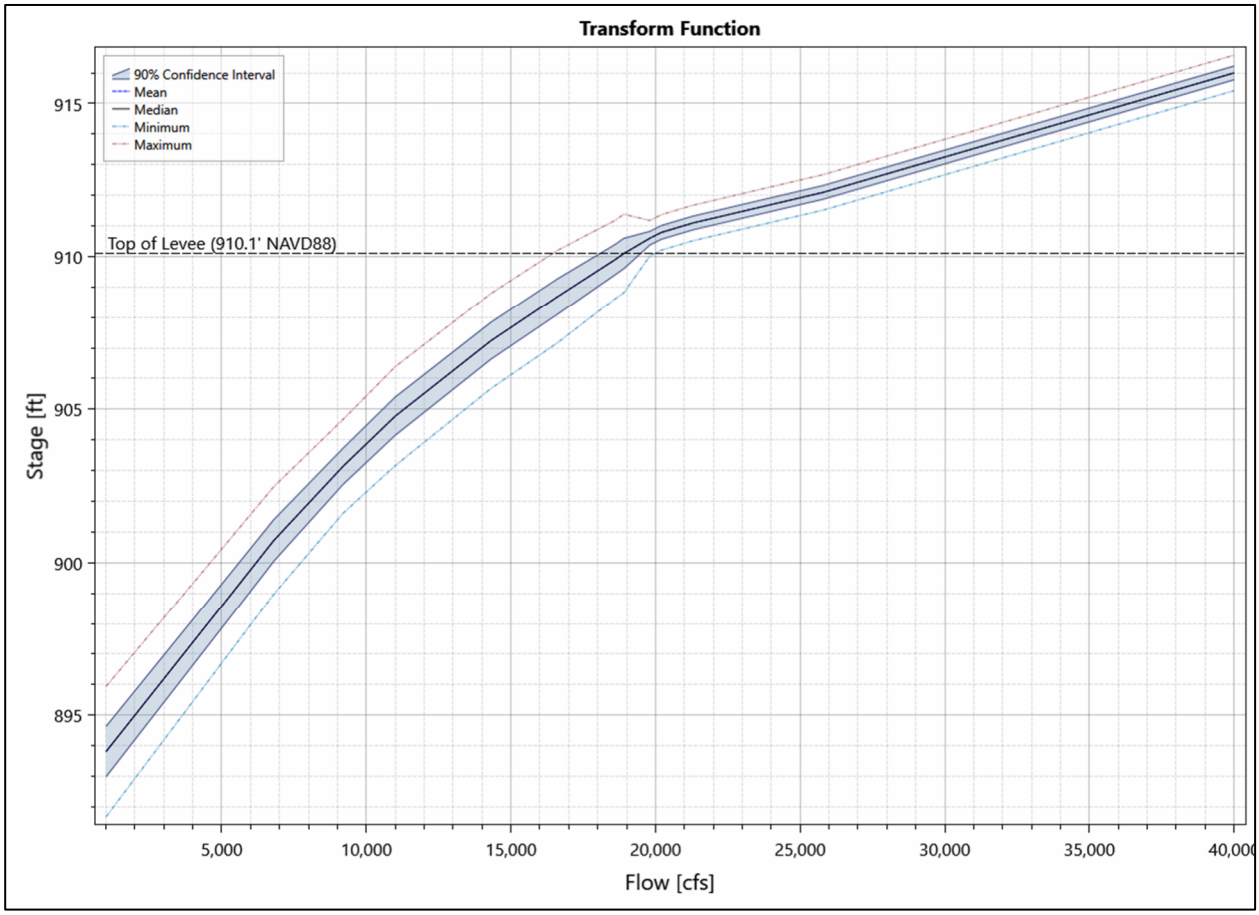

Figure 35. Elevation-discharge relationship and uncertainty at LCL (Channel STA 65+40).

Table 19. Change in flows between Johnson Drive and LCL location.

AEP	Flow at Johnson Drive (cfs)	Flow at LCL (Channel STA 65+40) (cfs)
0.5	6,700	6,800
0.2	8,900	9,200
0.1	10,600	11,000
0.05	13,900	14,300
0.02	16,000	16,600
0.01	18,000	18,600
0.005	19,600	20,200
0.002	22,200	21,300

The resulting stage-frequency curve (Figure 37) at the LCL with uncertainty was developed using RMC-TotalRisk by applying the flow-frequency and uncertainty for the hazard and the stage-discharge relationship and uncertainty as a transform. Uncertainty bounds were not developed as part of the design frequency flows form the HEC-1 outputs. Therefore, an effective record length of 25 years was entered in manually to represent the approximate gage record length of the Johnson Drive StormWatch gage. This flow-frequency curve was assumed to be representative of the LCL location given the little change in flow between Johnson Drive and the LCL as shown above in Table 23. Peak velocity and location for loading scenarios.

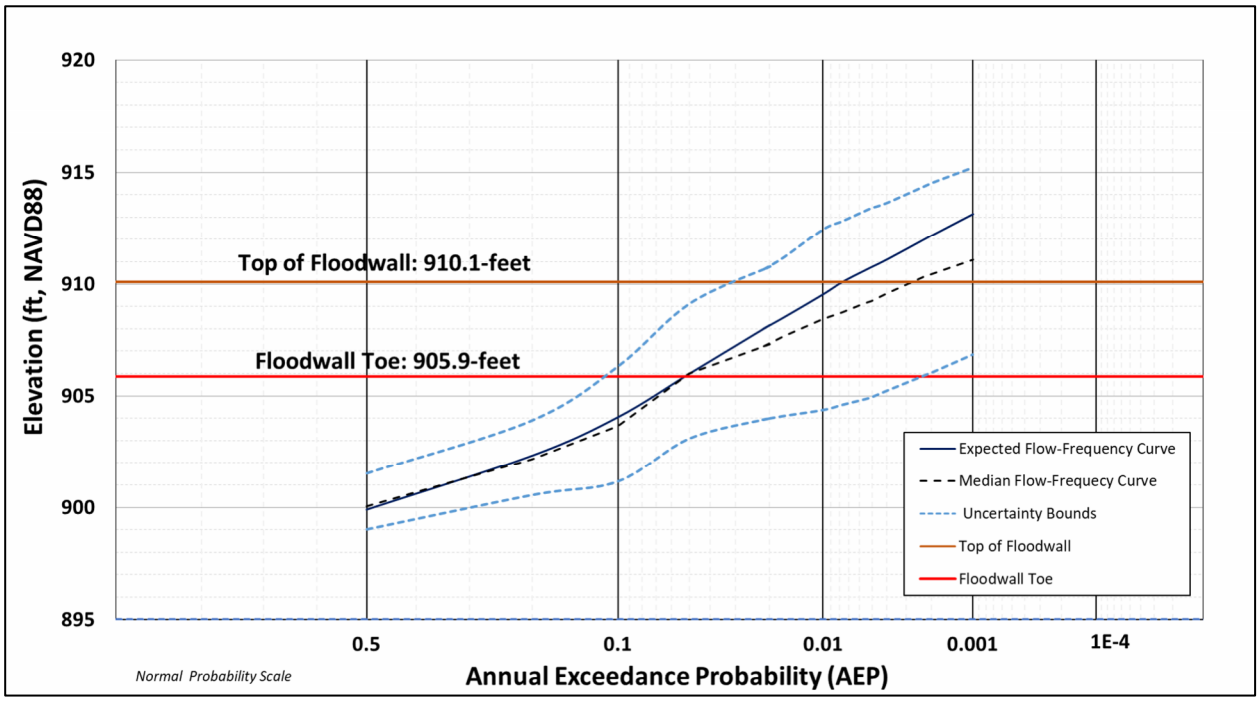

Figure 36. Elevation-frequency curve at LCL (Channel STA 65+40).

Based on the above computed stage-frequency curve in Figure 36, the incipient overtopping frequency at the identified LCL is approximately 7.65E-03 AEP (1/130yr) using the expected curve. This frequency seems realistic given that the levee was designed to the 0.01 AEP design flow with 85% reliability. Table 20 provides a summary of the stage frequency results including 0.5, 1, and 2-foot overtopping depths.

Table 20. Computed Stage-Frequency Results at LCL.

AEP	1/year	Expected Stage (feet)	Upper 90% CI Stage (feet)	Lower 90% CI Stage (feet)
1.00E-03	1,000	913.15	915.24	906.88
2.00E-03	500	912.19	914.53	906.04
2.13E-03 (2ft (OT)	470	912.10	914.46	905.99

4.4.6. Levee System Profile

The proposed configuration has a left-bank and right-bank alignment. The left bank flood protection begins near Shawnee Mission Parkway and ties into high ground near Johnson Drive bridge. The left-bank system then resumes in a separate segment near Merriam Drive Bridge. The right-bank flood protection extends from Shawnee Mission Parkway all the way to just downstream of Merriam Drive Bridge. Figure 37 and Figure 38 detail the alignments and stationing for the left-bank and right-bank, respectively. It should be noted that alignment stationing is different for the left and right bank systems. A channel centerline stationing is used to correlate the levee alignments as shown in Table 21.

Table 21. Alignment stationing crosswalk.

Channel STA	Left Bank STA (and wraparound STA)	Right Bank STA
0+40	13+10 (11+70)	-
2+00	14+85 (10+10)	-
4+00	17+25 (8+35)	-
6+00	19+30 (6+40)	-
8+00	21+50 (4+55)	-
10+00	23+20	-
15+00	28+05	6+25
20+00	33+00	11+50
25+00	37+70	16+70
30+00	43+10	21+40
35+00	47+55	28+65
40+00	52+20	32+00
45+00	56+90	37+05
50+00	62+85	41+85
55+00	68+60	46+40
60+00	73+75	51+40
65+00	80+30	55+90
65+66	-	56+70

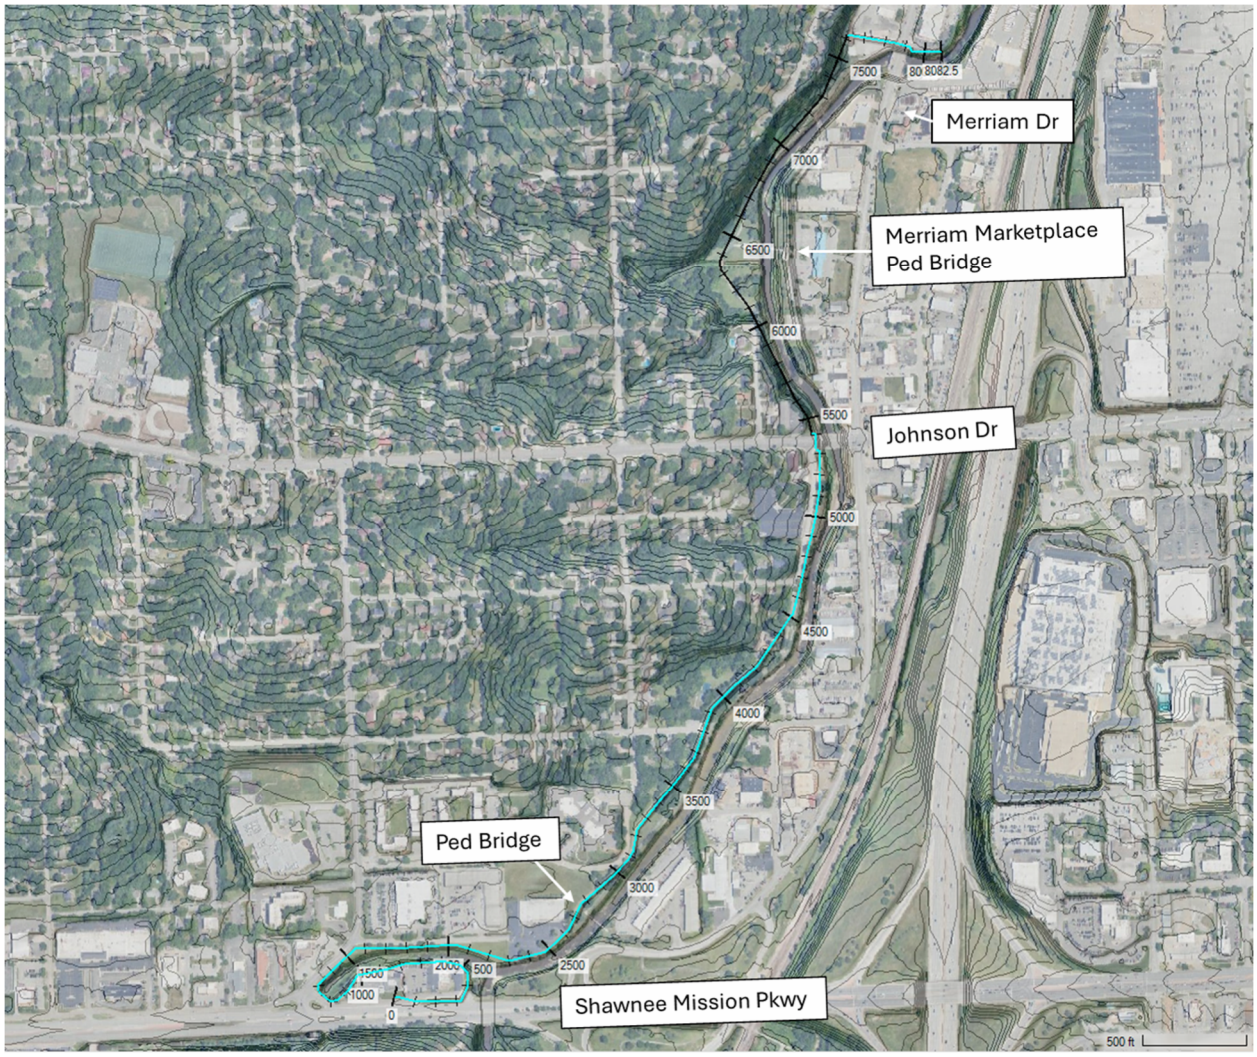

Figure 37. Left-bank flood protection alignment.

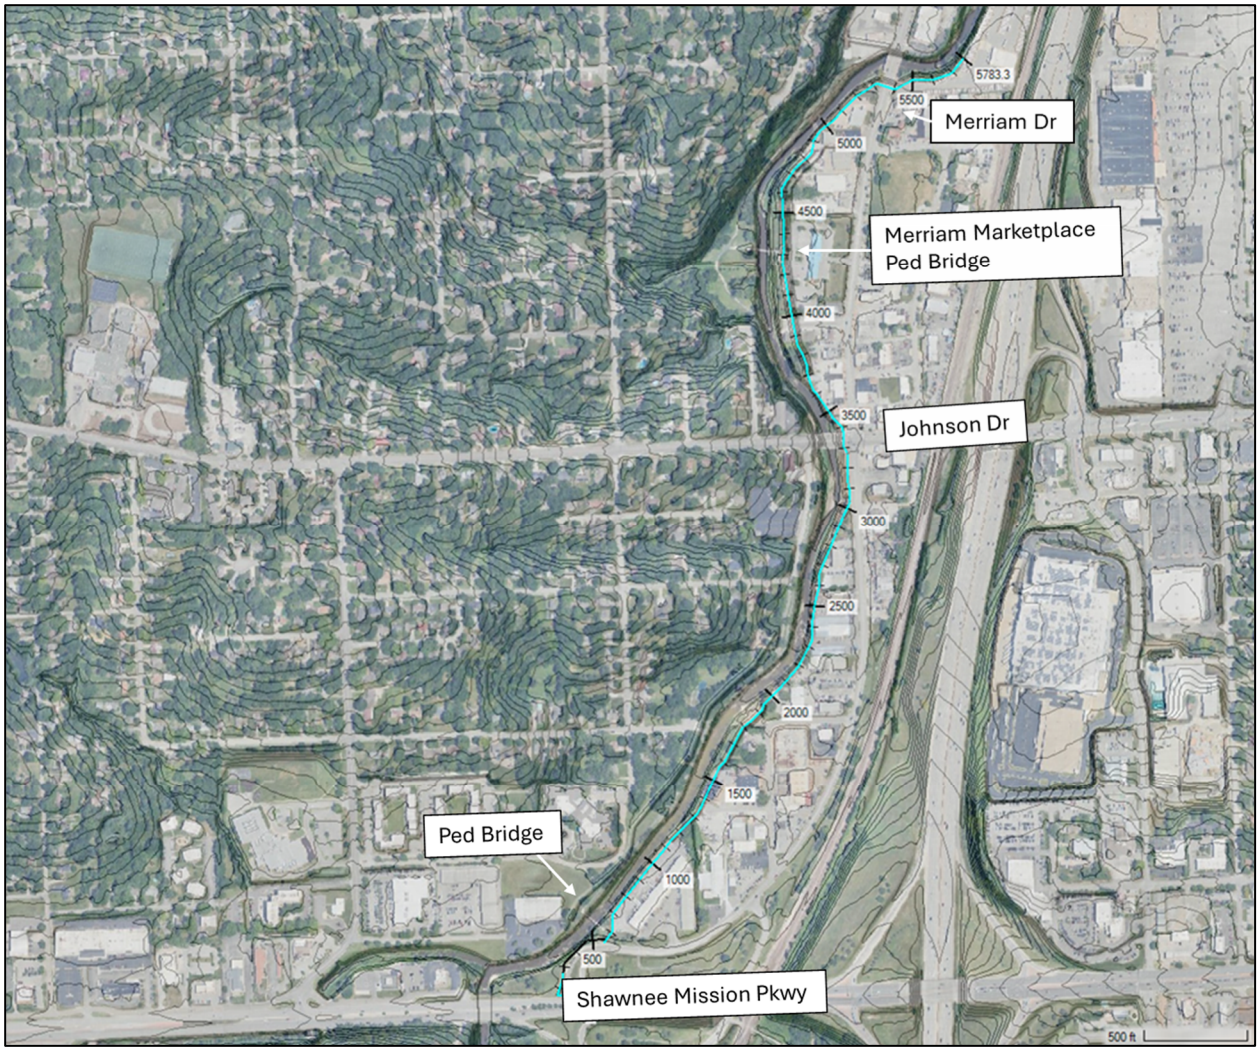

Figure 38. Right-bank flood protection alignment.

A levee system profile was developed in excel with hydraulic modeling results and relevant system features. The profile plots were broken into two separate figures, a left bank and right bank plot. The left and right bank levees have their own stationing which was utilized for each respective plot. Profiles such as the channel invert and water surface profile were represented using the levee stationing. Chosen breach locations for the SQRA were also plotted. It should be noted that the left bank levee profile increases in elevation at the upstream end of the system with increasing stations before sloping back down. This is the portion of the levee that wraps around the small tributary. Approximate left bank levee stations 11+50 through 13+50 represent the most upstream end of the tributary project extents.

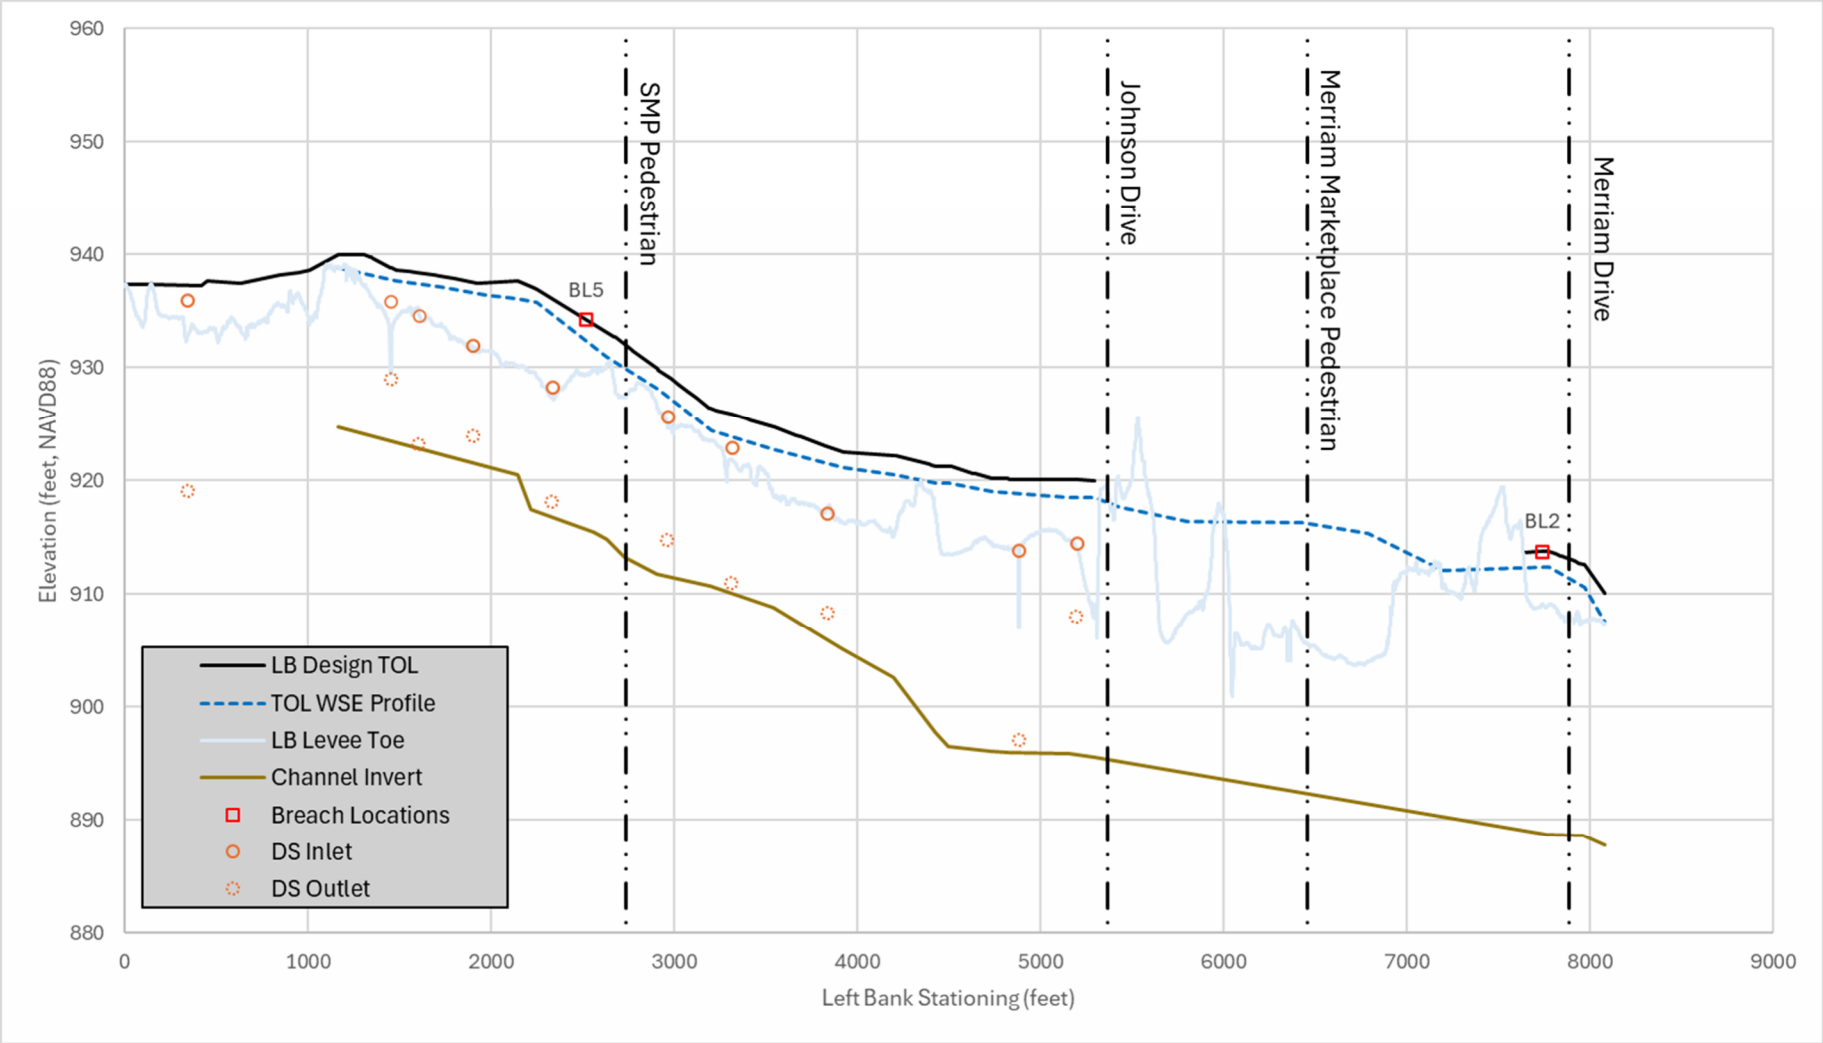

Figure 39. Left Bank comprehensive system profile with relevant hydraulic, observed, and system profile data points.

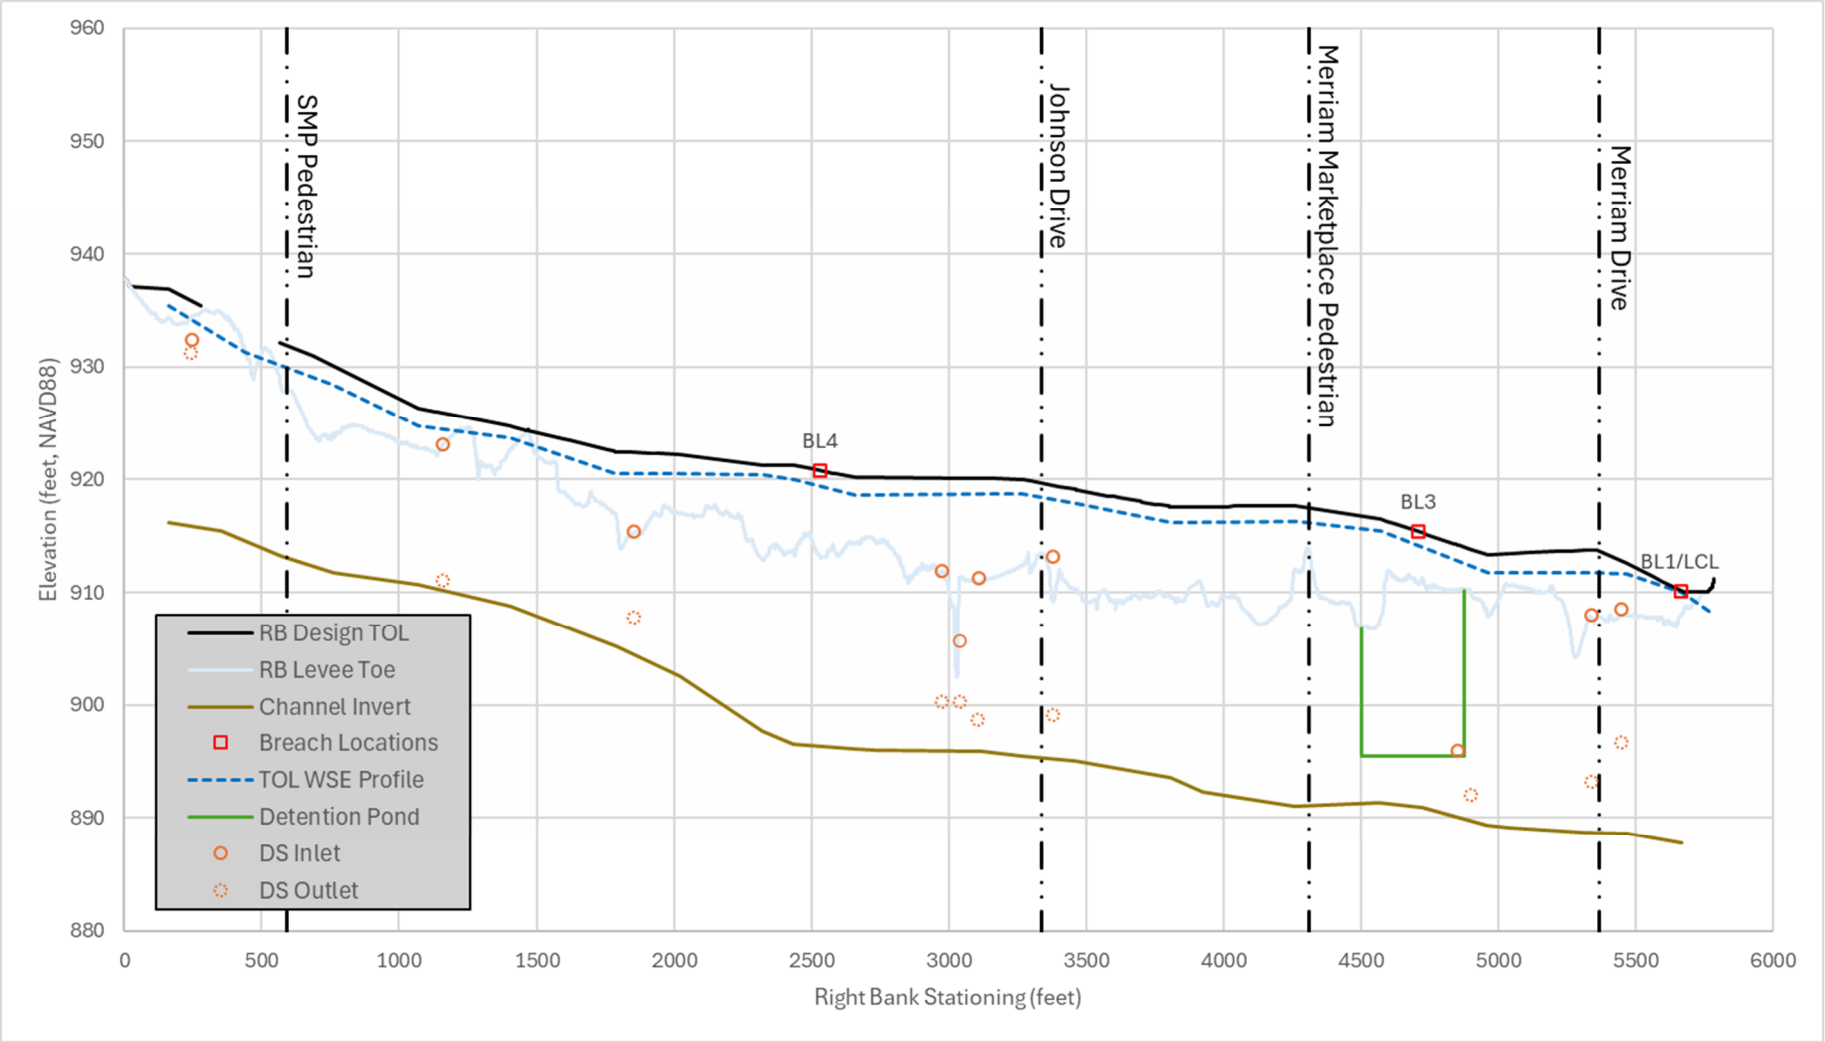

Figure 40. Right Bank comprehensive system profile with relevant hydraulic, observed, and system profile data points.

4.4.7. Overtopping

The synthetic frequency inflow hydrographs were scaled and routed through the hydraulic model to hit peak stages at the LCL that result in 0.5 ft, 1 ft, and 2 ft of overtopping. The resulting durations of overtopping, within 0.1 feet of peak, and duration above toe were extracted from the model results as an estimate of duration for the overtopping potential failure mode (PFM). Depth and duration summaries are shown in Table 22 and Figure 41.

Overtopping durations are very short, even for the more extreme 2-foot overtopping loading condition. Durations above the toe elevation at the LCL are also very short. This is likely because the LCL location occurs at a portion of floodwall that is only approximately 2 feet tall. Breach parameters based on the overtopping scenarios are discussed later in Chapter 6.

Table 22. Overtopping depth and duration summary at LCL.

Peak Overtopping Depth (ft)	Total Overtopping Duration	Peak Overtopping Stage Duration (within 0.1 ft of peak)	Duration Above Toe (Elev 907.9 feet)
0.5	0.5 hrs	0.25 hrs	1 hr
1	1 hr	0.1 hrs	1.5 hrs
2	1.5 hrs	0.25 hrs	1.67 hrs

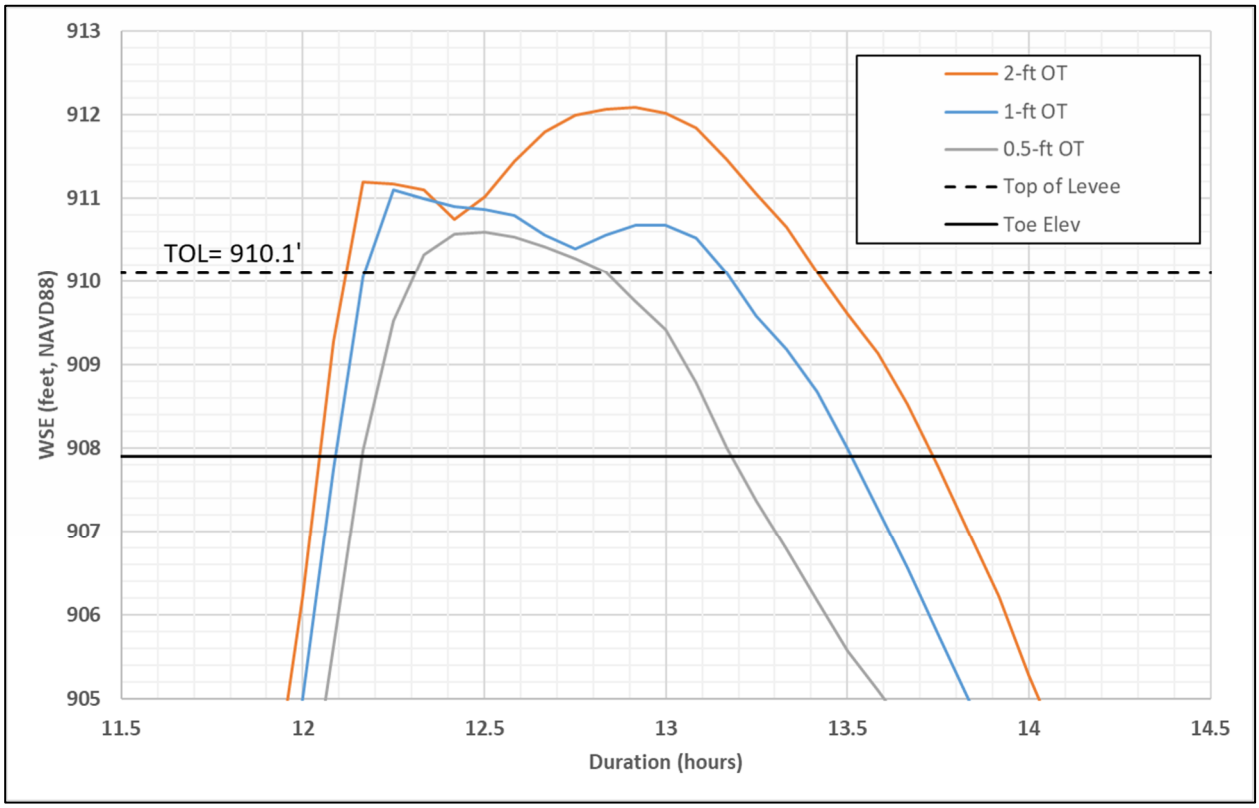

Figure 41. Expected overtopping durations at LCL based on routing the scaled synthetic hydrographs in the model.

4.4.8. Outflanking

Based on the current design, there is some slight outflanking on the left bank downstream end of the proposed levee system. The levee ends without tying into any high ground. This is due to the recently recomputed levee profile which may require some realignment to find appropriate high ground. Outflanking at this location seems to occur at approximately the same time as overtopping at Merriam Bridge on the left bank as seen in the below figure. The outflanking is not expected to contribute much to incremental consequences given that the flow mainly spills onto Merriam Drive and not the surrounding elevated properties.

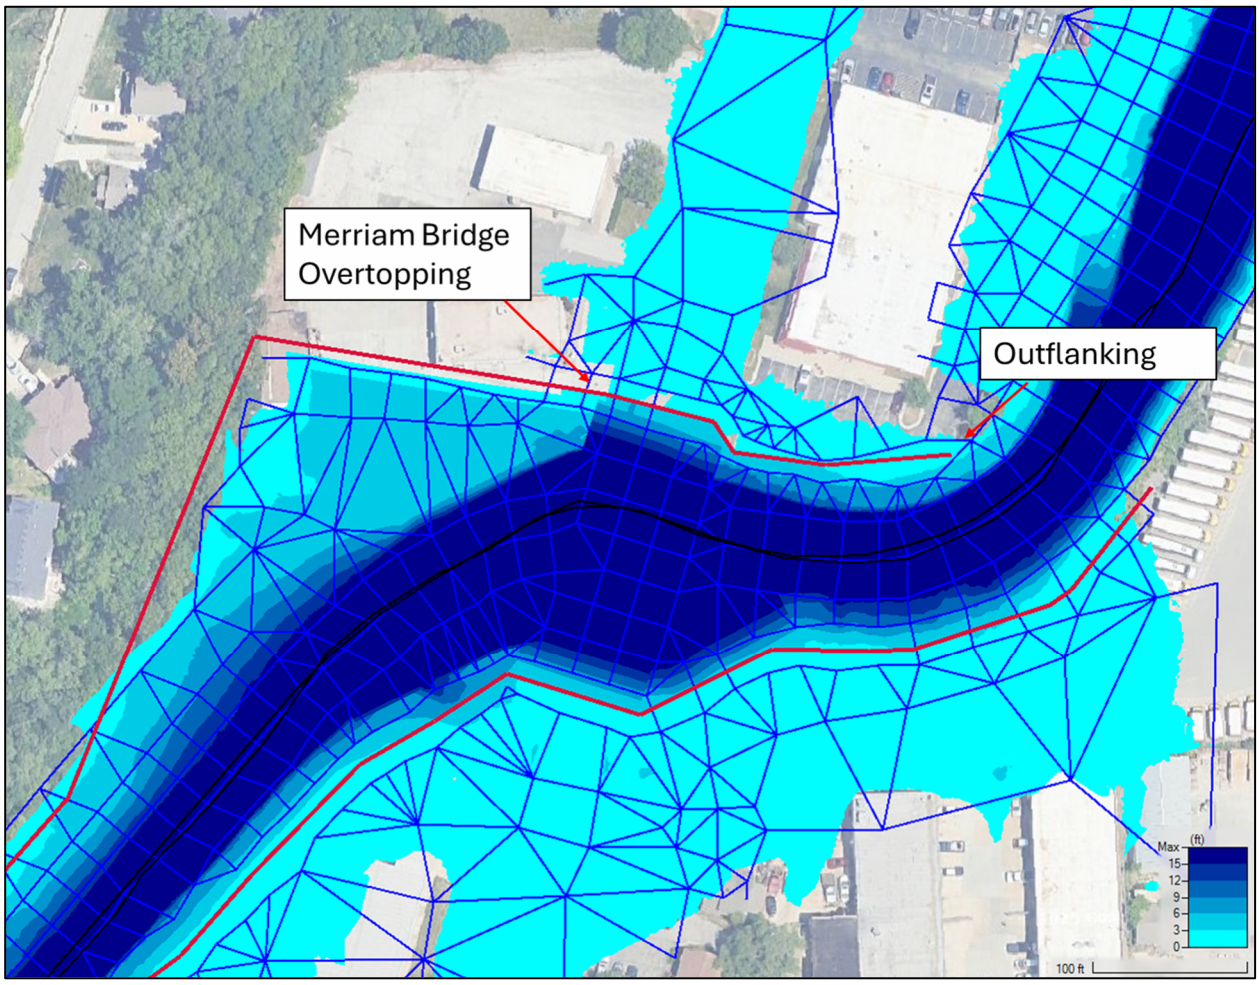

Figure 42. Outflanking of left bank floodwall at end of project.

4.5. Supporting Analyses

4.5.1. Riverine Velocity Estimates

Riverine velocity ranges from approximately 6 to 18.5 feet per second along the channel centerline for the top of levee loading scenario. Locations of higher velocities are generally located at pinch points where the levee alignment on the left and right banks narrows down. Areas of low velocities exist around bridges where flow is backed up against the upstream bridge face as well as the portion of the channel between Johnson and Merriam drive bridges where there is no left bank levee or floodwall.

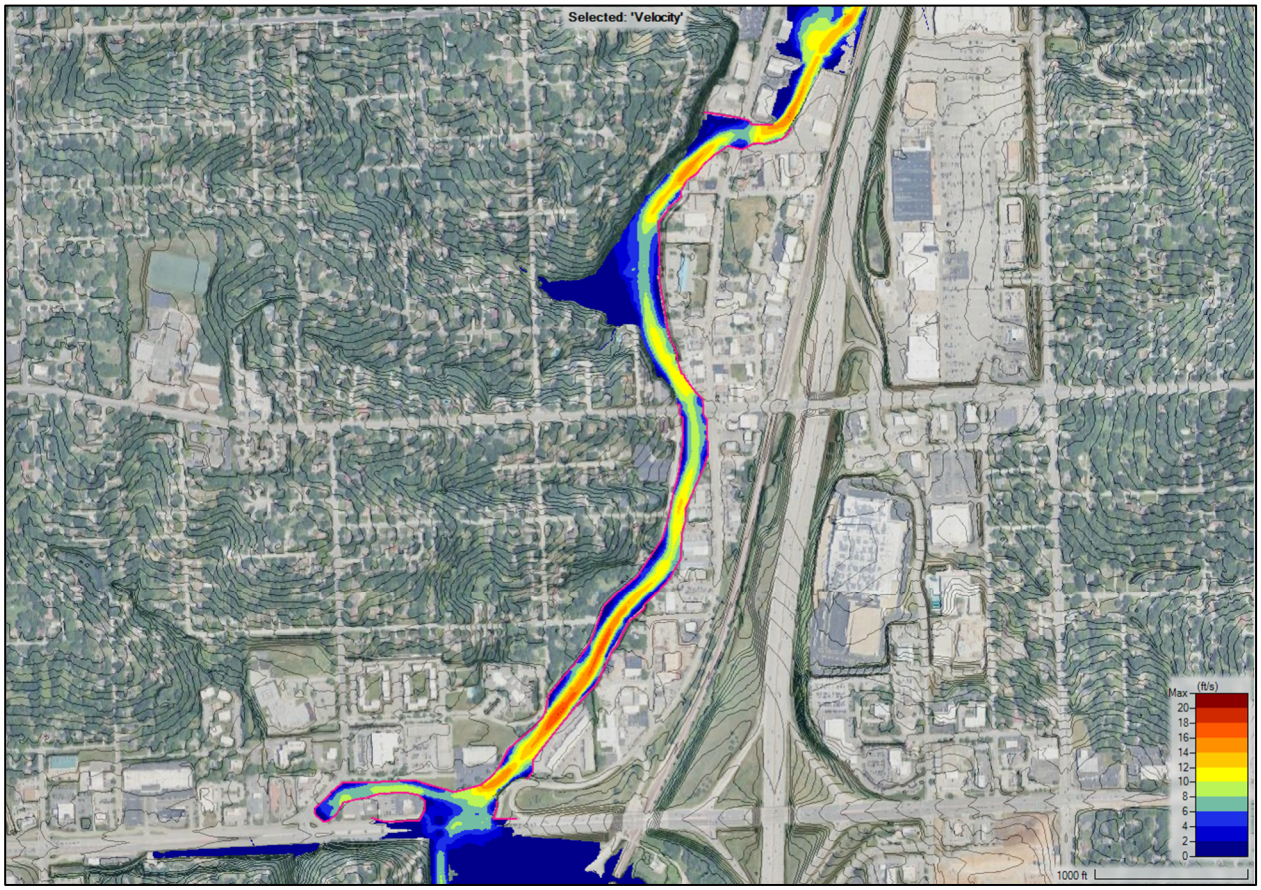

Figure 43. Peak velocity mapping for top of levee loading scenario.

Velocities increased with increasing overtopping depth scenarios. Most notable magnitude change in velocities were around river station 26+00 to 41+00 as shown in Figure 44. Peak velocity and velocity locations are shown in Table 23. Like the top of levee scenario, max velocities are occurring in straightaways in the channel near pinch points in flow conveyance area, or more specifically, top width. Outside bends do not seem to be a driving factor of max velocity locations, likely because the channel is already so constrained by levees and/or floodwalls on either side. Table 24 also provides a summary of peak and average increase in velocity for the overtopping scenarios when compared to top of levee loading. These locations of max increase are likely because the top of bridge decks begin to overtop and the damming effect of the upstream face of the bridges diminishes.

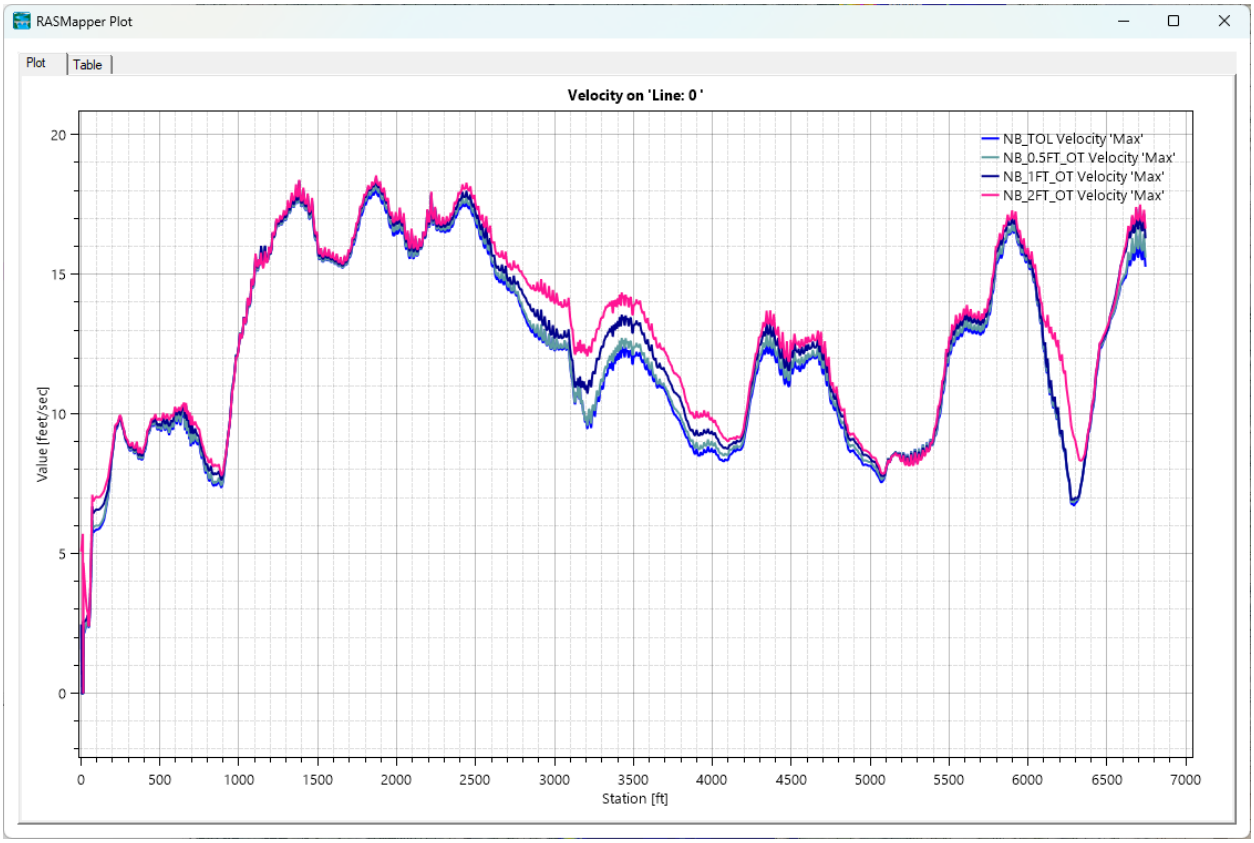

Figure 44. Velocity profile plot for loading scenarios.

Table 23. Peak velocity and location for loading scenarios.

Loading Scenario	Peak Velocity (ft/s)	Location of Peak Velocity (STA, feet)	Description
TOL	18.2	13+80	Constriction point immediately upstream of Shawnee Mission Parkway pedestrian bridge
0.5ft OT	18.3	18+70	Constriction point approximately 400’ downstream of Shawnee Mission Parkway pedestrian bridge
1ft OT	18.5	18+70	
2ft OT	18.5	18+70	

Table 24. Average and peak change in velocity from top of levee loading for overtopping scenarios.

Loading Scenario	Average Change in Velocity (ft/s)	Peak Change in Velocity (ft/s)	Location of Peak Change in Velocity (STA, feet)
0.5ft OT	0.1	0.3	34+80 (~700’ upstream of Johnson Drive)
1ft OT	0.4	1.5	32+60 (~900’ upstream of Johnson Drive)
2ft OT	0.8	2.8	62+40 (60’ upstream of Merriam Drive)

4.5.2. Wind-Wave Estimates

There is no known history of wind-wave estimates along Turkey Creek. Due to the short loading durations and general topography of the area preventing suitable fetch distances, wind-wave action is not considered a concern.

4.5.3. Overtopping Velocities

The LCL is located along a floodwall with asphalt pavement on the landside toe. Because of this, velocities or plunge scour were not estimated at this location. For the purposes of the SQRA, overtopping velocities were estimated at a representative levee section of 10 feet tall. These are used to estimate grass stripping on the landside of the levee for breach modeling and elicitation of levee overtopping failure modes. Breach locations are shown below in Figure 45. Breach locations 2 and 3 are at levees on the left and right bank, respectively. Overtopping depths and velocities are summarized in Table 28. Justifications for the chosen breach locations are discussed in Chapter 6.

Figure 45. Breach locations.

Table 25. Overtopping depths and normal depth velocities at 10-foot levee section.

Loading Scenario	AEP (1/year)	Peak Velocity (ft/s)	Velocity at landside edge of crest (ft/s)
0.5 ft OT	5.56E-03 (1/180-year)	8.3	2.8
1 ft OT	4.00E-03 (1/250-year)	12.6	4.0

2 ft OT	2.13E-03 (1/470-year)	18.7	5.7

Normal depth velocities were calculated to be used for estimating grass stripping. The critical flow was computed at the landside edge of the levee crest to help inform erosive energy at the crest for potential failure mode analysis. Table 29 below summarizes the parameters and assumptions used to compute the overtopping velocities.

Table 26. Overtopping velocity estimation parameters

Parameter	AEP (1/year)
Levee Height (ft)	10
Crest Width (ft)	10
Levee Slope (ft/ft)	0.33
Slope Roughness	0.02
Crest Roughness	0.03
Weir Coefficient	2

4.5.4. Interior Drainage and Ponding

Current designs for interior drainage include a detention pond and numerous gravity drainage structures along the left and right banks of the levee system to prevent ponding of the interior. Pump stations are not being considered in the design due to the flashiness of the system and the general understanding that there is not enough warning time get personnel there in time to operate the pumps. Interior drainage is being modeled separately from the levee design channel hydraulics.

The current design of the detention pond is sized for a 0.1 AEP event, which was part of the recommended design plan from the feasibility study. The detention pond layout and depth is still being refined, but the current size was implemented into this geometry as a terrain modification so it could be considered during overtopping and breach scenarios of the levee and/or floodwalls. An outlet structure will drain any ponded water through the levee and into Turkey Creek.

The drainage structures are all gravity drains with passive flap gate closures. Pipes with diameters of 48 inches or above currently are designed with a dual closure system. The second closure being another passive system (flap gate or duckbill) inside the gate well. Figure 46 details the locations of the currently proposed drainage structure locations and detention pond. An active secondary closure such as a sluice gate is not likely to be beneficial, again because of the flashiness of the watershed. It is unlikely personnel would be able to get out in time to close a sluice gate. Additionally, the interior area is likely to experience the same storm event that is driving the riverine flooding, and improper timing of sluice gate closure runs the risk of worsening interior ponding if it is not allowed to drain under gravity conditions.

Figure 46. Proposed drainage structure locations.

Interior drainage capabilities are not part of the model used for the SQRA; therefore, it was not included in the modeling. The assumption for this SQRA model is that any overtopping or breach scenarios will lead to ponding of the interior under gravity denied conditions for the duration of event. The detention pond was assumed to be empty for all loadings and breach scenarios so that it can be shown how overtopping flow or breach flow drains into the pond, potentially mitigating life safety or economic consequences. It should be noted a storm event capable of producing overtopping loading will also cause significant interior flooding in the project area. Modeling coincident interior flooding and channel flooding would be beyond the scope of this assessment.

It should be noted that a design criteria waiver is being pursued for the dual closure requirement for drainage structures larger than 36 inches. This would result in just a single flap gate closure on the riverside of the flood protection system, similar to drainage structures less than 36 inches in diameter. Below are two examples of larger diameter drainage structures with a single flap gate being stuck fully open for the full duration of a top of levee loading event. The first is drainage structure ST-15 (48-inch diameter RCP) on the left bank, shown in Figure 47. The second is drainage structure ST-20 (48-inch diameter RCP) on the right bank just upstream of Johnson Drive bridge, shown in Figure 48.

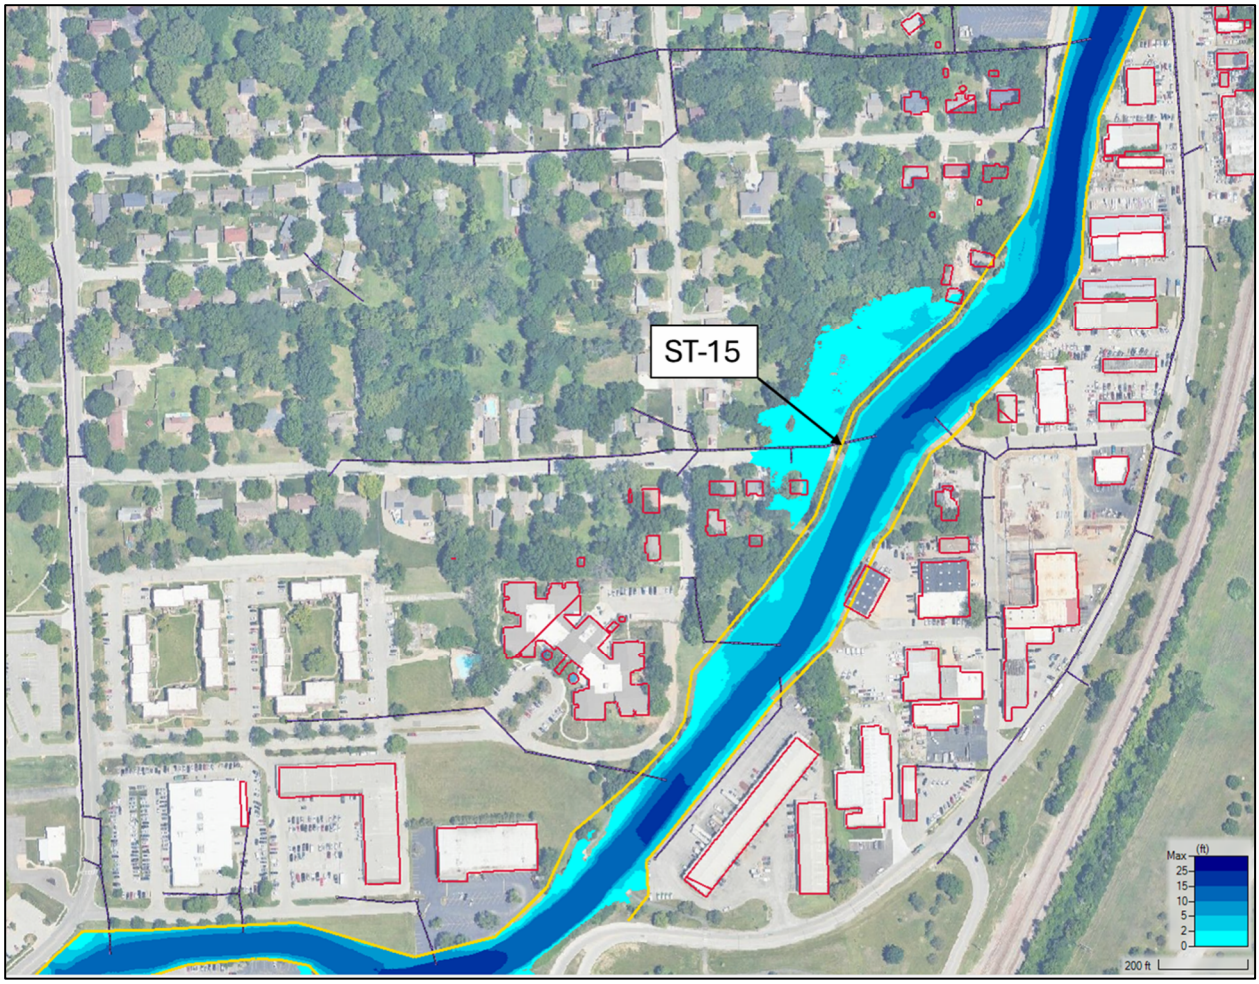

Figure 47. Interior flooding with drainage structure ST-15 flap gate stuck fully open.

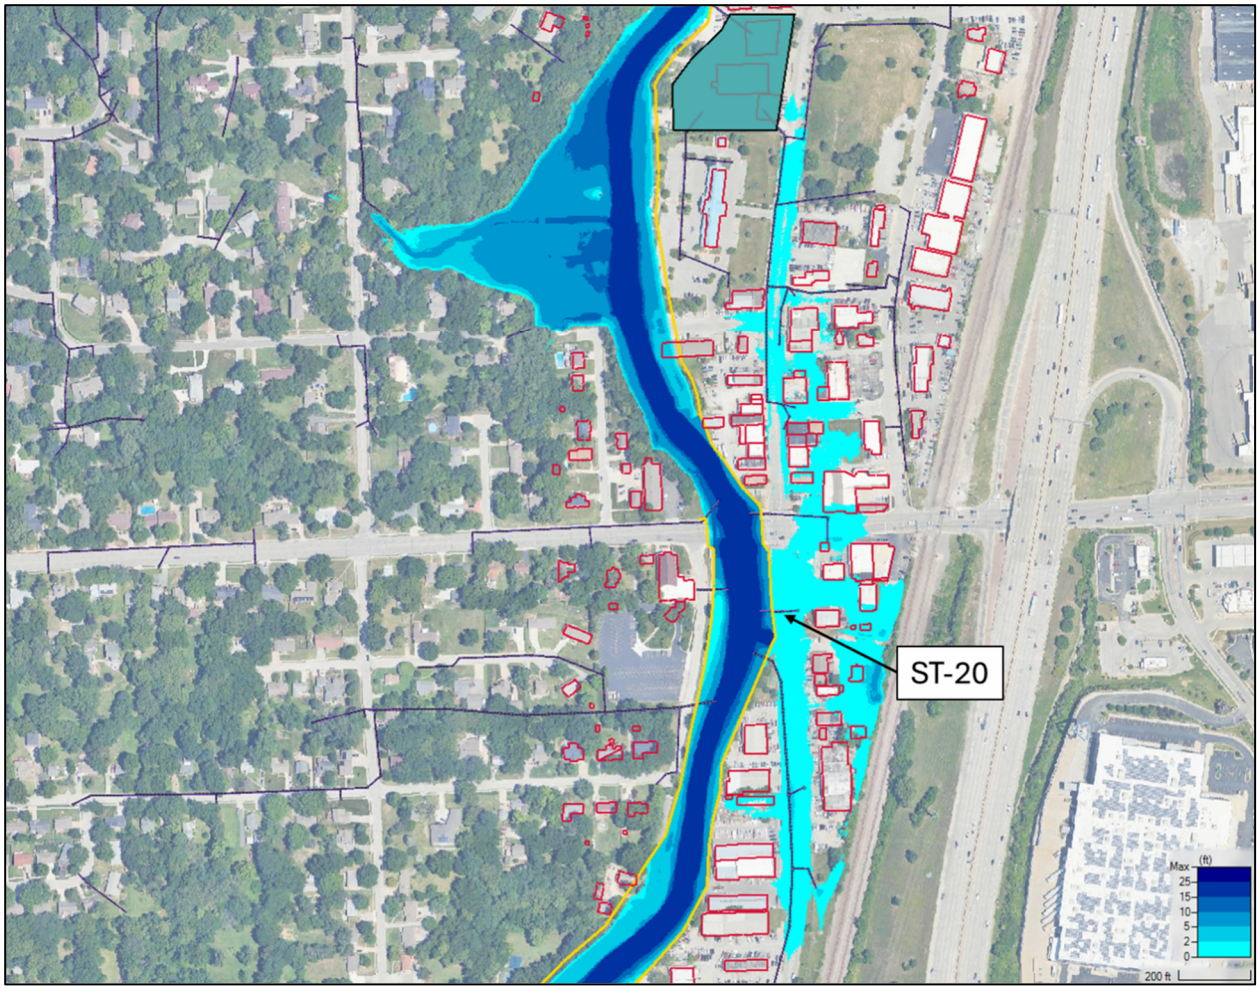

Figure 48. Interior flooding with drainage structure ST-20 flap gate stuck fully open.

Inundation depths in both scenarios are almost entirely less than 2 feet deep, which poses little risk of life loss. Inundation is mainly contained to park land, streets, and parking lots, with some buildings seeing inundation of less than 2 feet.

4.5.5. Bridges and Inline Structures

Bridges are modeled as 2D connections in the HEC-RAS model. The bridges have an impact on the hydraulic profile depending on the flow scenario. It should be noted that Johnson Drive and Merriam Drive bridges are planned to be replaced as part of the design and are being implemented into the flood protection system. The current design has these two bridges being replaced and raised so that they do not overtop during the 0.01 AEP (1/100yr) event. This allows the project design team to remove the need for closure structures such as stoplog gaps or swing gates on either side of the bridges. The reason for not including closure structures on the bridges is due to the flashiness of the system and the low likelihood of having personnel out to the system in time to operate the closures. Additionally, there are two pedestrian bridges located within the project extents. These are not being removed or replaced but do influence the hydraulic profile and velocities as previously discussed. Figure 50 below details the locations of the bridges within the project extents.

It was assumed that any guardrails or pedestrian rails on the upstream and downstream faces of the bridges would not convey flow. This was to account for uncertainty in the flow conveyance capacity that the spaces between railing would present as well as uncertainty in debris blockage that would occur. Bridge dimensions are based either on USACE survey data or dimensions provided for current replacement bridge designs.

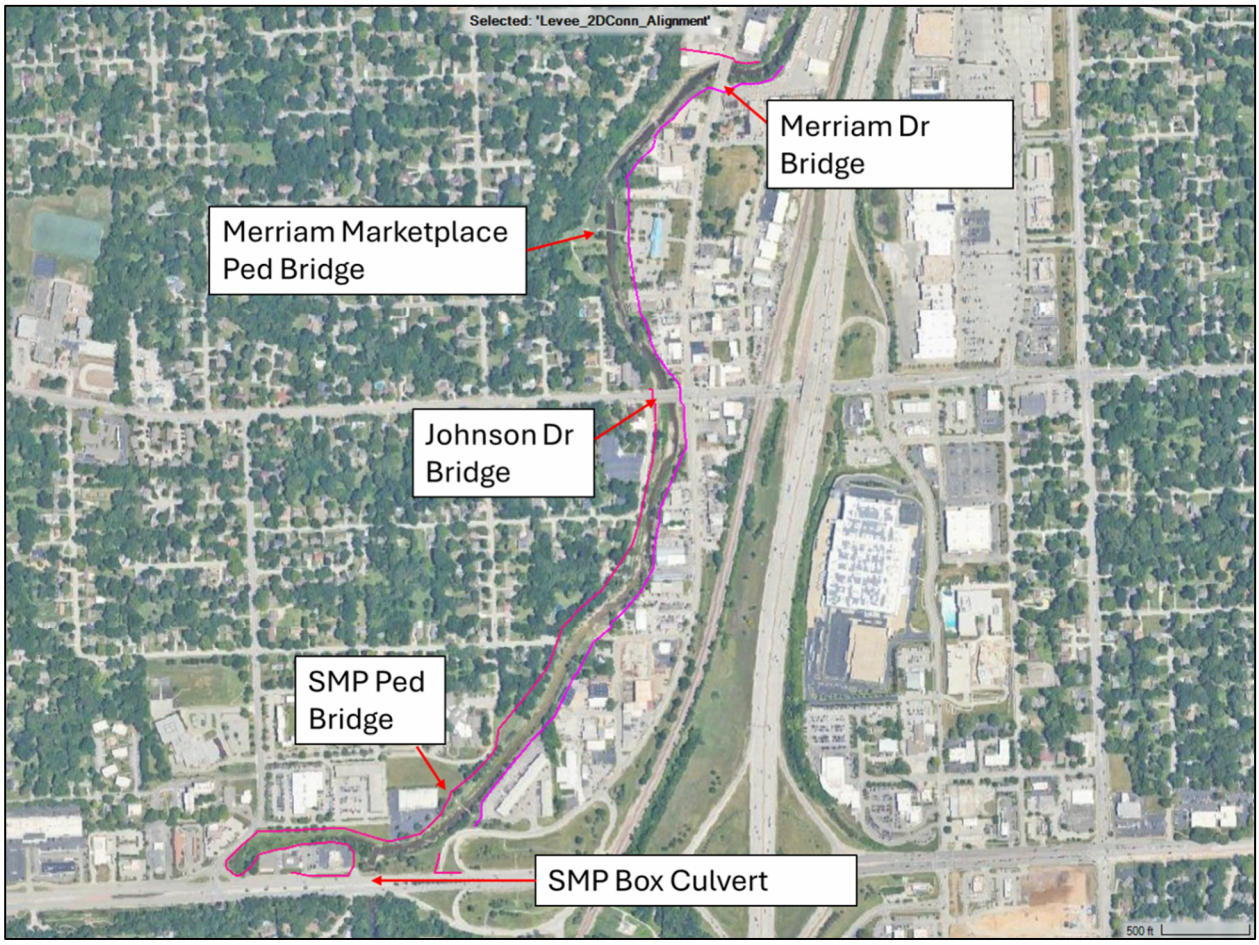

Figure 49. Bridge locations.

4.5.6. Ice and Debris Effects

No incidents of ice or debris jams have been noted in previous flood documentation. Based on historic documentation, flooding generally occurs during non-freezing months of the year.

4.5.7. Sediment Impacts

After the August 2017 flood, a survey of sediment deposits was conducted in November 2017 and again in the summer of 2018. This was used to update the Southwest Boulevard rating curve for the Lower Turkey Creek project. These updates and survey data were included in the Turkey Creek 2018 Sediment Analysis Report. The report did not include any analysis of the upper portion of Turkey Creek, instead looking at three primary reaches of lower Turkey Creek. The restored channel and walled channel reaches have experienced sediment deposition while the natural reach immediately upstream experienced primarily erosion.

For upper Turkey Creek, a significant portion of the channel upstream of the project extents and the extents themselves are lined with block wall channels. This likely reduces the magnitude of erosion and sediment transport to the project area that the lower portions of Turkey Creek experience, both in typical flows over time and flood events.

The tributary just south of Shawnee Mission Parkway appears to have experienced notable sediment deposition between 2010 and 2023 (and beyond) as seen in Figure 50 and Figure 51 below. The LiDAR for the model terrain was flown in 2020 and generally reflects the current sediment deposition at this location. Increased deposition such as the current conditions of the tributary lead to increased stages. Clearing out the channel would lead to improved conveyance capacity but would likely sediment back in over time unless added in as an operations and maintenance item. Similar issues are present further downstream near the Merriam Marketplace pedestrian bridge.

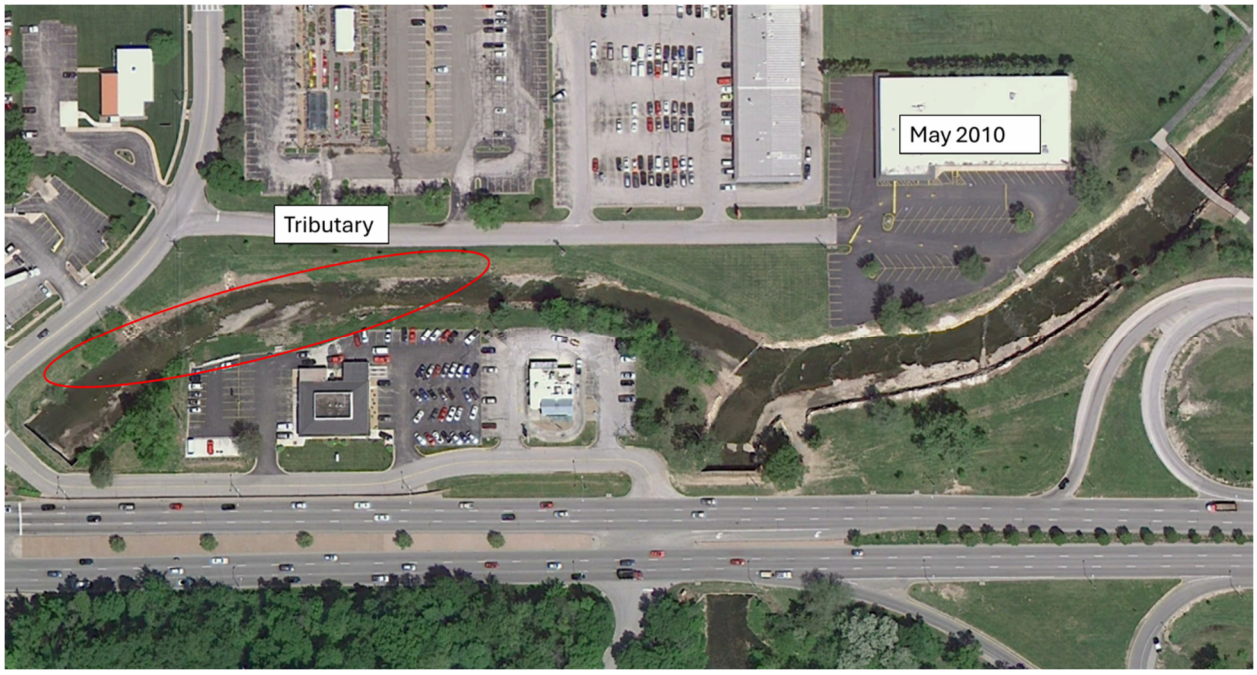

Figure 50. May 2010 Aerial of tributary sediment deposition.

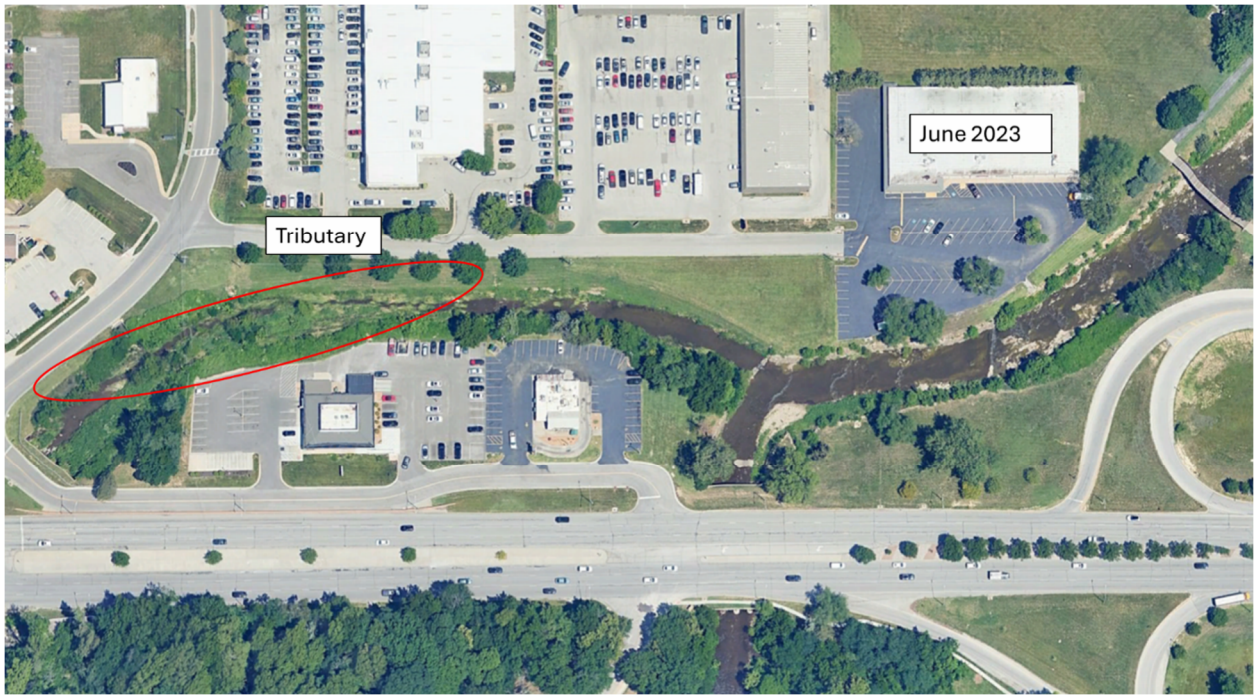

Figure 51. June 2023 aerial of tributary sediment deposition.

4.6. Major Uncertainties

There is major uncertainty in the hydrology due to a lack of consistent flow records anywhere along Turkey Creek, as previously discussed. The gage at Johnson Drive within the project area is not a USGS gage and does not record flow data, nor does it have an accompanying stage-discharge rating curve. Thus, an RMC-BestFit, flow frequency analysis is not possible to perform at this location. Instead, frequency flows (inflows) were developed using HEC-1, a hydrologic modeling software during the feasibility study, with Atlas 14 frequency precipitation depths for the 24-hour storm that would then be routed through the developed hydraulic model. Uncertainty is present in the duration and distribution of the frequency storm used in HEC-1 as this is often subjective and/or based on regional trends. Additionally, the Turkey Creek watershed is heavily urbanized and fully accounting for underground stormwater network routing and overland runoff is nearly impossible without significant additional data and time, which is out of the scope of this study.

There is major uncertainty in the hydraulic modeling because of a lack of useable calibration data. Despite the base HEC-RAS model being set up for 2D rain-on-grid modeling, there are significant limitations to its ability to route storm network flow which could drastically affect routing timings and therefore affect peak flow magnitude, timing, and hydrograph shapes in the Turkey Creek channel. Using historical gridded precipitation to calibrate historic storms may lead to unrealistic calibration parameters by compensating for the stormwater network routing limitations. For this reason, best engineering judgement was used for selection of the calibration parameters while leaning towards more conservative modeling assumptions to account for hydraulic uncertainty in the design. Recent considerations were given to simulating 2017 storm events in the HEC-1 model, if possible, to compute inflows for the current set up of the HEC-RAS model and calibration efforts. But this was beyond the time allotted and scope of this SQRA. Highwater marks from the 2017 flood are also available for calibration purposes should these historic inflows be computed in the future. But again, there is significant uncertainty in the historic flows and if they are representative of current conditions.

5. Seismic Hazards

5.1. Background

The levee is located at latitude 39.027318º, longitude -94.693427º in the central and eastern western United States. The 2023 update of the National Seismic Hazard Model (NSHM) by the U.S. Geological Survey (USGS) (Petersen et al. 2020) provides consensus-based regional analyses of seismic hazard, using Central and Eastern United States (CEUS) seismic sources, Western United States (WUS) seismic sources, combined geologic/geodetic information, and revised ground-motion models. This report represents the most current assessment of seismic hazard for large regions of North America. The 2023 NSHM declustered seismicity catalog is shown in Figure 52.

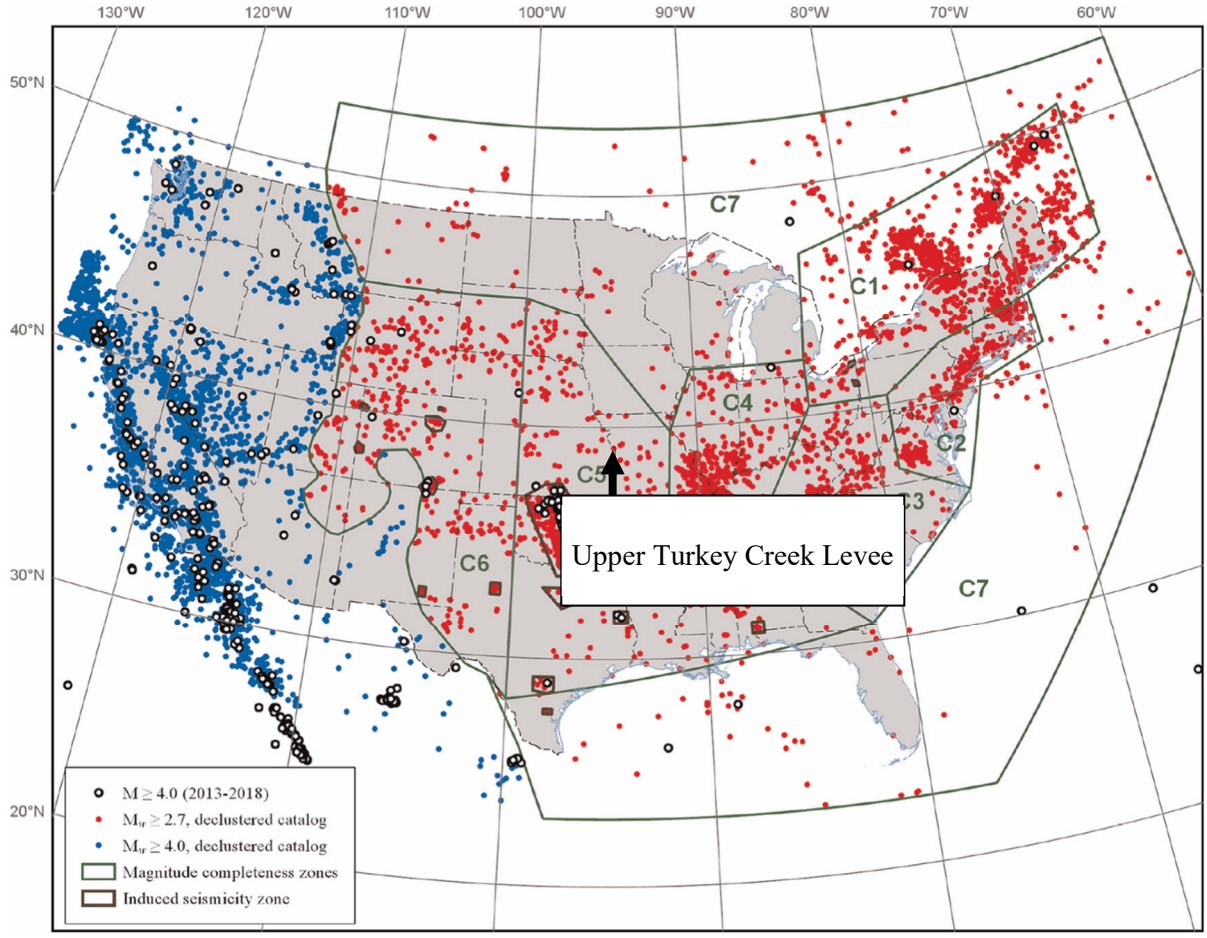

Figure 52. 2018 NSHM declustered seismicity catalogs for $M_w \geq 2.7$ (Petersen et al. 2020)

The NSHM for the CEUS considers both seismicity-based background earthquake source zones and fault-based sources and utilized data and models from the CEUS Seismic Source Characterization for Nuclear Facilities (CEUS–SSCn) project, which accounts for broader uncertainties and replaces older seismic source models. The seismicity-based source model for the CEUS assumes that future large earthquakes are more likely to nucleate near previous earthquakes with moment magnitude (M_w) greater than or equal to 2.7. The model also distinguished seismotectonic zones in the CEUS with distinct seismicity and

maximum earthquake magnitudes, in order to accommodate some possibility that the historical seismicity does not fully represent likely sources of background earthquakes.

The dam lies in the "North American Craton" seismotectonic zone but is less than about 520 kilometers west of the "Paleozoic Rift" seismotectonic zone, as shown in Figure 53, and could be affected by strong ground shaking resulting from earthquakes in either of these zones. The two seismotectonic zones have slightly different rates of seismicity occurrence, as well as interpreted maximum earthquake magnitudes. Peterson et al. (2014) indicate that it is reasonable to expect an earthquake with M_w between 6.5 and 7.8 could happen in the craton.

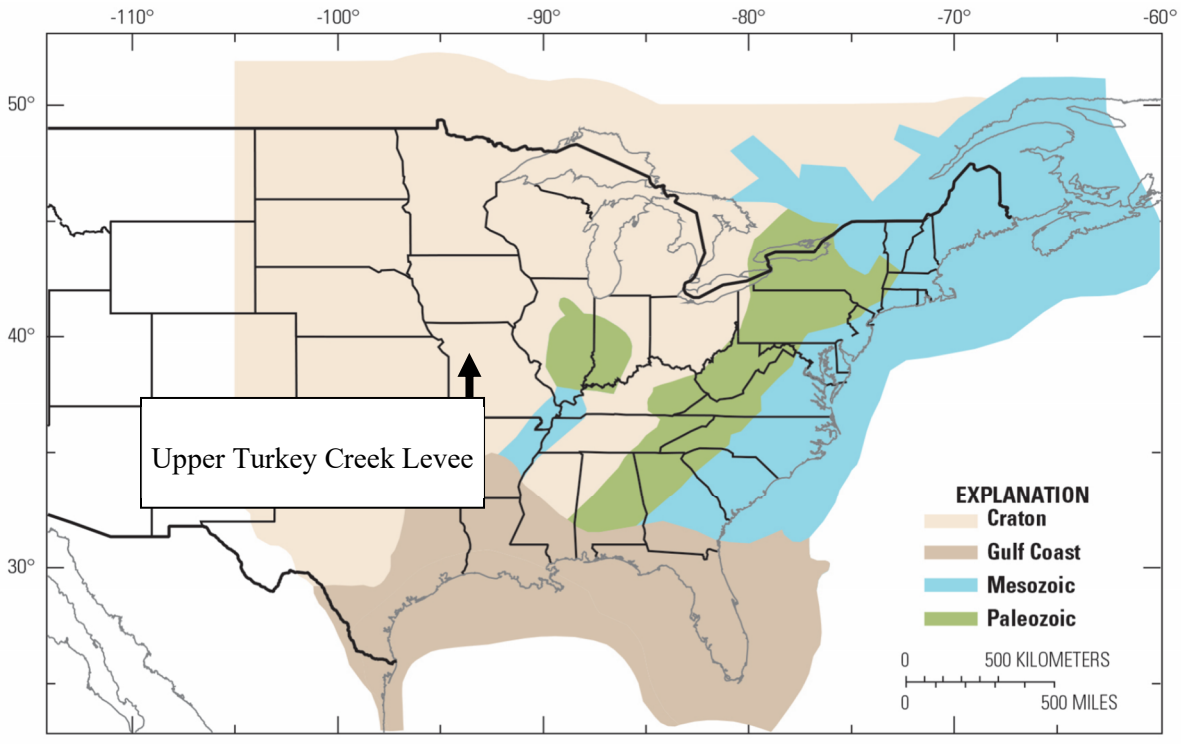

Figure 53. 2018 Generalized seismotectonic zonation of the CEUS (CEUS-SSCn 2012)

The USGS Quaternary Fault and Fold Database of the United States and interactive fault map (https://doi.org/10.5066/F7S75FJM) were reviewed for faults and associated folds in the vicinity of the site that demonstrate geological evidence of coseismic surface deformation in large earthquakes during the past 2.58 million years (Myr). The results are portrayed in Figure 54 and summarized in Table 27.

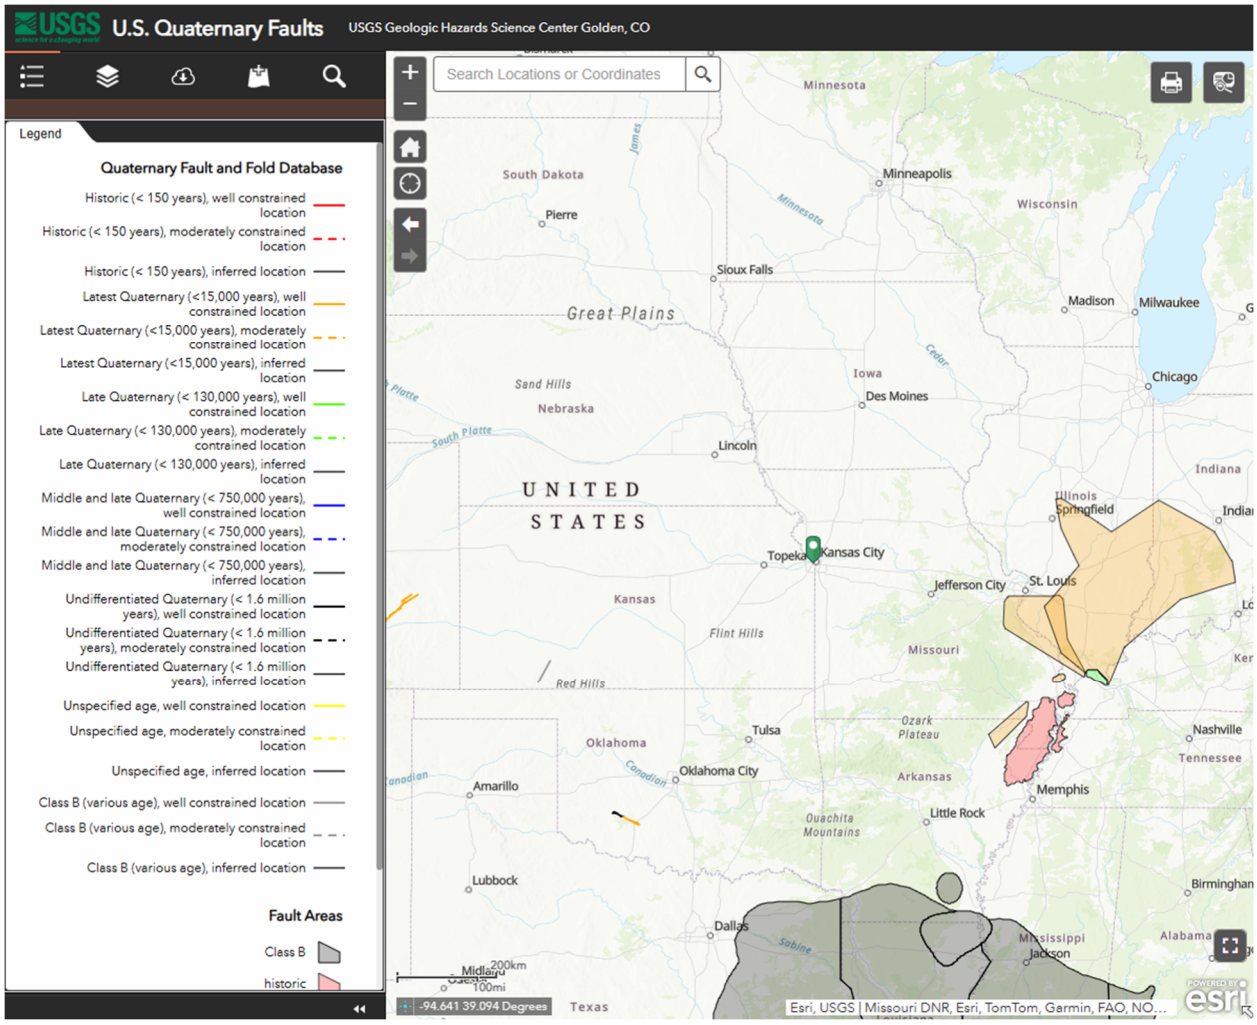

Figure 54. Quaternary faults (USGS 2025)

Table 27.
Quaternary faults (USGS).

Name	Primary County, State	Length (km)	Time of Most Recent Deformation	Slip-Rate Category
St Louis-Cape Girardeau Liquefaction Features	Multiple Counties in Missouri and Illinois	542 (perimeter)	<15 ka	No data

NOTE: https://doi.org/10.5066/F7S75FJM accessed on 15 APR 2025.

5.2. Historical Seismicity

The USGS Earthquake Catalog was searched for events with magnitude (M) greater than or equal to M4.5. Figure 55 summarizes these events with respect to magnitude and epicentral distance. Table 28 provides details of some selected earthquakes of interest.

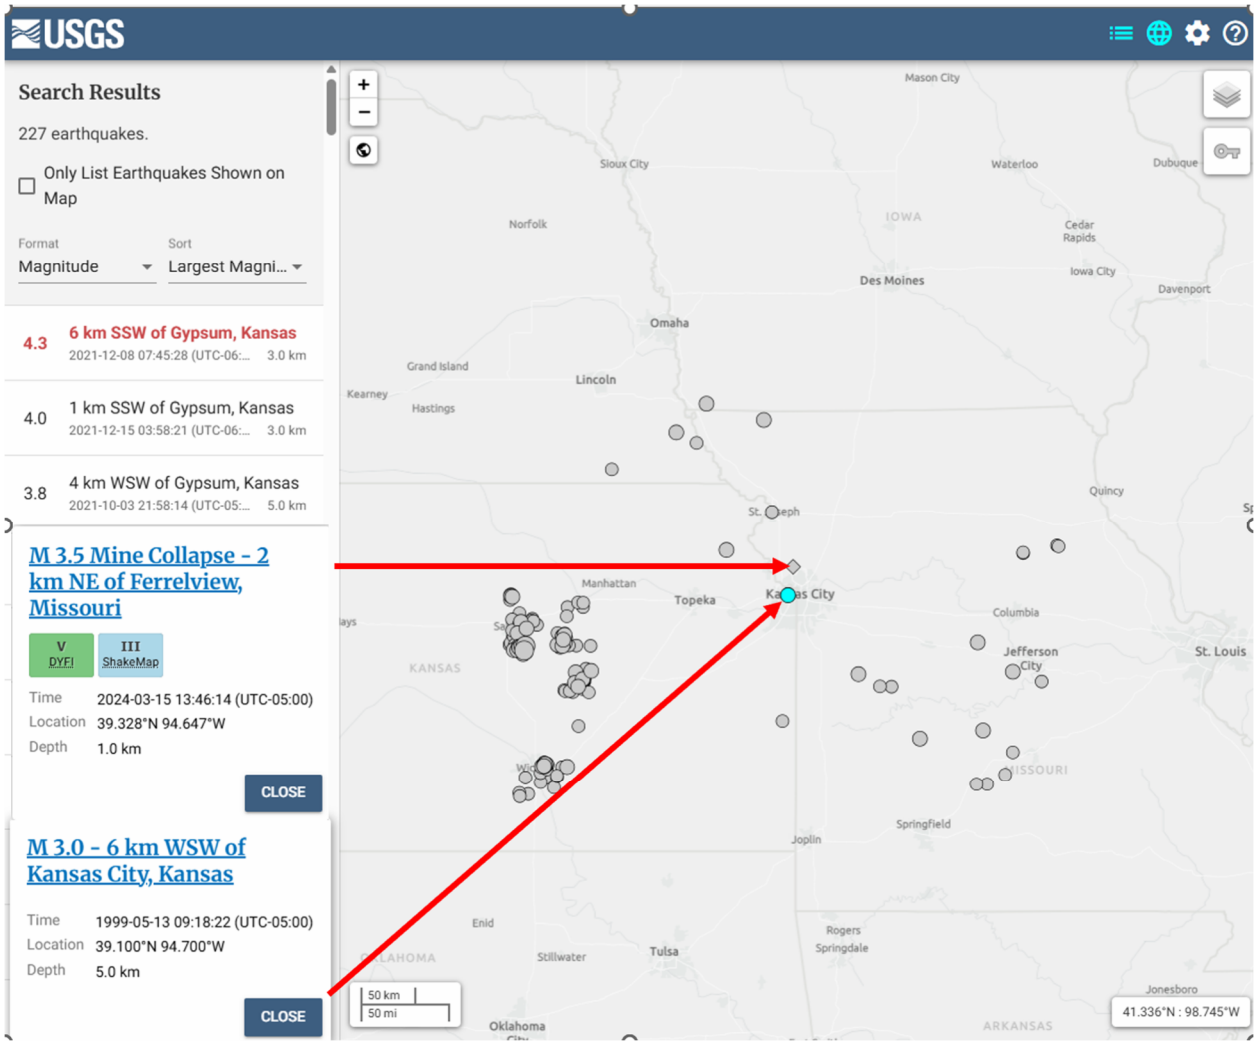

Figure 55. Historical seismicity near the Upper Turkey Creek Project Area since 1960 (USGS 2025)

Table 28.
Historical seismicity since 15 APR 1960 (USGS).

Magnitude Interval	Search Radius from Site	Number of Events
4.5 ≤ M < 5	10 mi (16 km)	0
5 ≤ M < 6	50 mi (80 km)	0
6 ≤ M < 7	75 mi (121 km)	0
7 ≤ M < 8	125 mi (201 km)	0
M ≥ 8	200 mi (322 km)	0

NOTE: https://earthquake.usgs.gov/earthquakes/search/ accessed on 15 APR 2025.

20 OCT 1965	Centerville, Missouri	4.6	37.479	-90.944	7.0	375

NOTE: https://earthquake.usgs.gov/earthquakes/search/ accessed on 15 APR 2025.

5.3. Induced Seismicity

There are currently active deep injection wells for wastewater or other fluids within 20 kilometers of the site.

Increases in seismicity in the CEUS have been documented since about 2009. Most of the human-induced earthquake activity in the CEUS is caused by injection of wastewater or other fluids into deep disposal wells that causes pressure changes that can weaken a fault and therefore bring it closer to failure (Petersen et al. 2017). The seismic hazard may be higher in these areas of potentially induced seismicity than the hazard depicted in the NSHM. Assessing the hazard is difficult because induced seismicity can vary rapidly in time and space based on changes in wastewater injection which can be caused by economic or policy decisions (Petersen et al. 2016).

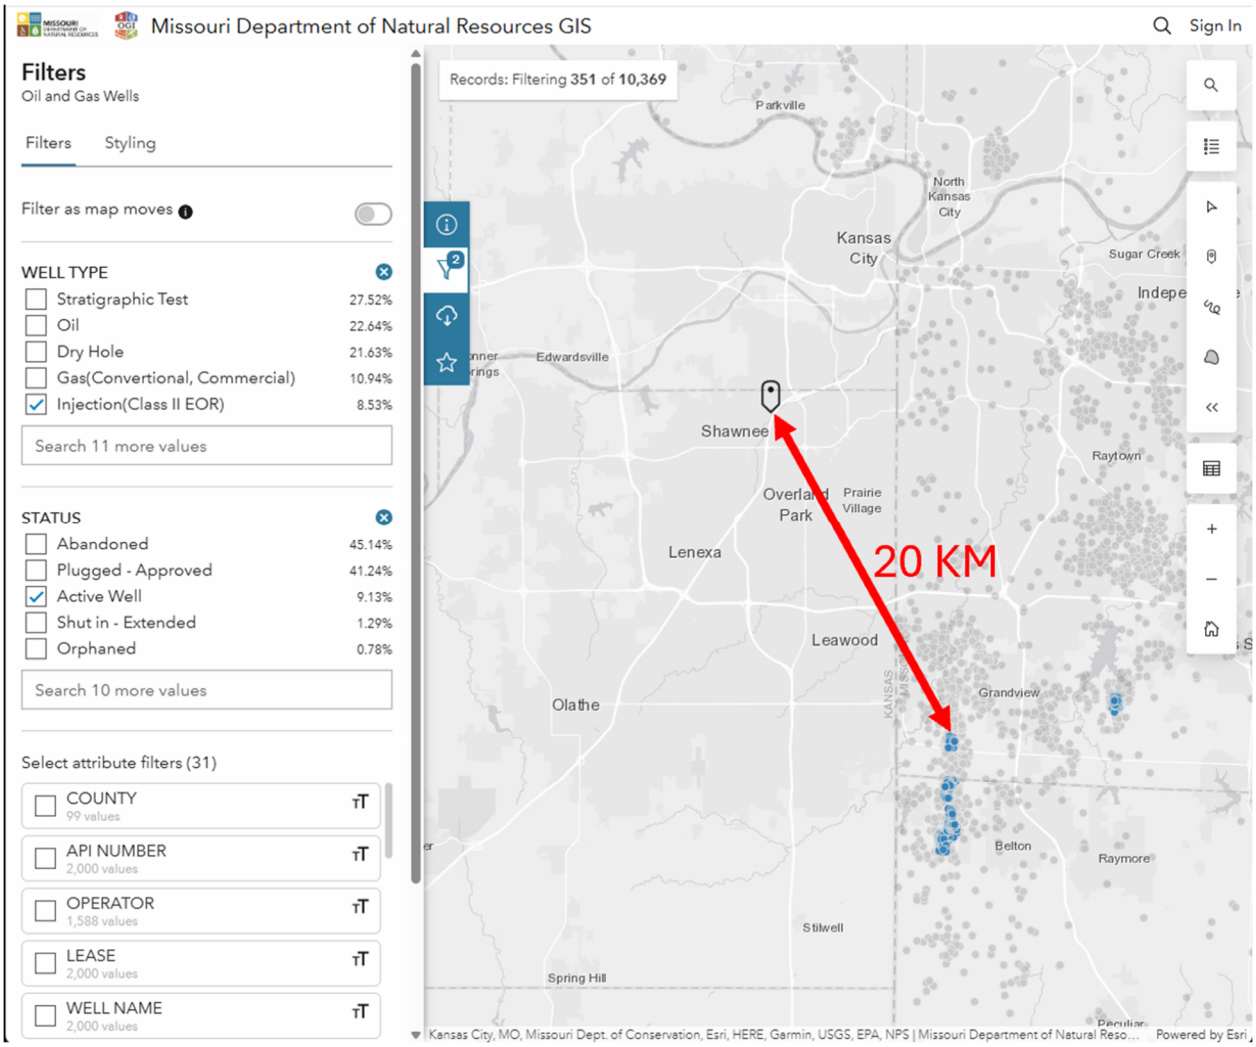

Figure 56. Injection Wells within 20 KM of the Upper Turkey Creek Project Area (MODNR 2025)

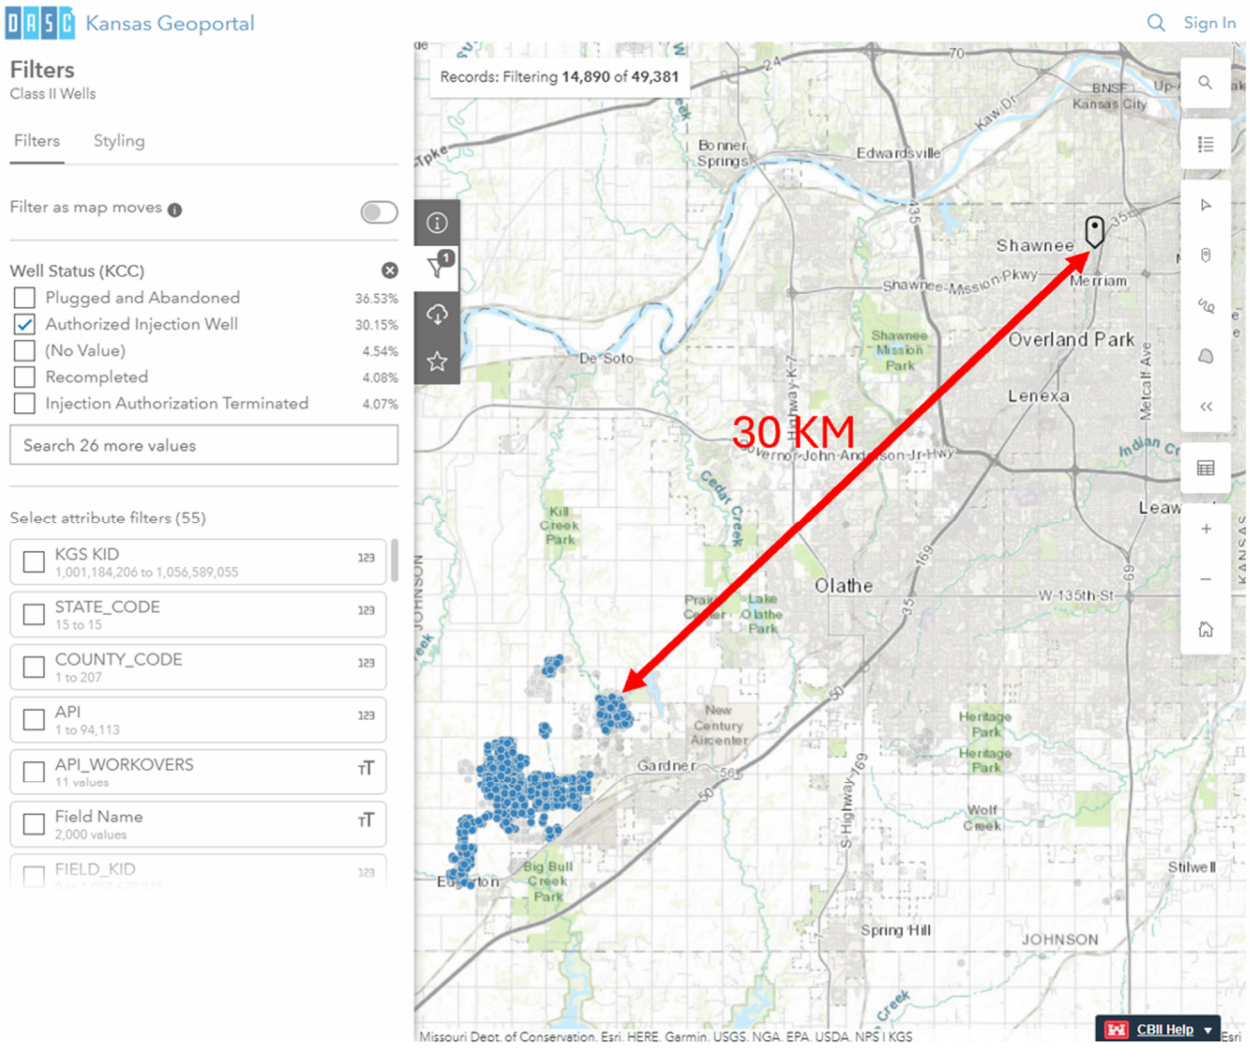

Figure 57. Injection Wells within 20 KM of the Upper Turkey Creek Project Area (KGS 2025)

5.4. Site Classification

The dam is founded on Pleistocene and Holocene alluvium that has a maximum thickness of about 8 to 18 feet over bedrock. The subsurface materials consist predominantly of clay and silt, with some gravel at the top of weathered bedrock.

The shear wave velocity (v_s) is the velocity that shear waves, such as those produced by an earthquake, will have as they pass through the soil or bedrock. For the purposes of estimating ground motions, the foundation soil and rock profile can be classified based on the average shear wave velocity in the uppermost 100 feet (30 meters, v_{s30}) of the site profile. The v_{s30} is currently the preferred parameter for characterizing (classifying) the site conditions in developing estimates of ground shaking using ground motion attenuation relationships.

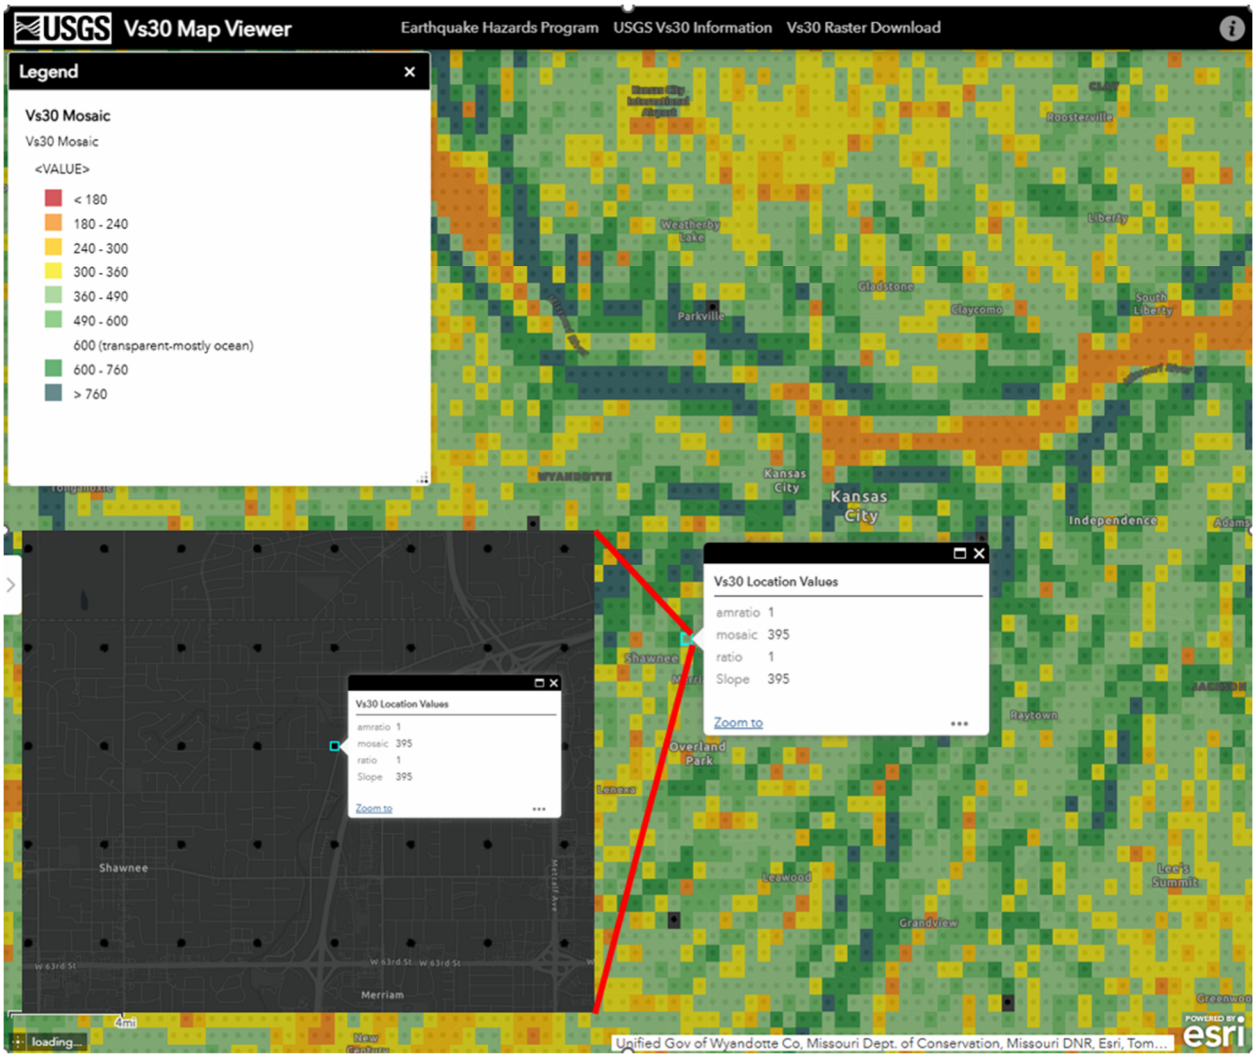

Figure 58. USGS Compilation Values of v_{s30} in the United States (McPhillips, D.F., Herrick, J.A., Ahdi, S., Yong, A.K., and Haefner, S., 2020, Updated Compilation of VS30 Data for the United States: U.S. Geological Survey data release, https://doi.org/10.5066/P9H5QEAC**).**

Shear wave velocity data was not available for the site. The USGS has compiled measured v_{s30} funded by the USGS and other governmental agencies for thousands of sites in the US (https://earthquake.usgs.gov/data/vs30/us/). The time-averaged shear-wave velocity (v_{s30}) of 1296 feet per second (ft/s) (395 meters per second (m/s)) was judged appropriate for estimating purposes for the site. Therefore, the foundation corresponds to Site Class CD, according to the National Earthquake Hazards Reduction Program (NEHRP), but Site Class D was still used as a conservative approach.

Shear wave velocity data was available for the site at the USGS website, but the value used on the website was not used. The overburden thickness at the valley center was at most 25 feet of lean clay and gravelly clay above bedrock. SPT field-measured blow counts (N_{ch}-values) of the 25 feet cohesionless soils typically ranged from 0 to 38 blows per foot (bpf), with an average of 8 bpf. Undrained shear strengths (s_u) of the 25 feet of cohesive soils ranged from 1043 to 2766 pounds per square foot (psf), with an average value of 1853 psf. The underlying rock generally consisted of hard, interbedded limestone and

sandstone, and the rock layers to a depth of 100 feet were assigned N_{ch} of 100 bpf or s_u of 5,000 psf. Since the average SPT blow count ($\overline{N}_{ch}$) was 8 bpf and the average undrained shear strength ($\bar{s}_u$) was 1853 psf, the foundation corresponds to Site Class D, according to the National Earthquake Hazards Reduction Program (NEHRP). Based on the $\overline{N}_{ch}$ of 8 bpf and $\bar{s}_u$ of 1853 psf the foundation corresponds to Site Classes E and D, respectively, according to the National Earthquake Hazards Reduction Program (NEHRP). Therefore, the site was assigned the softer site class of Site Class D. It should be noted the shear wave velocities of the shallow bedrock are unknown and only the upper 8-10 meters of the v_{s30} profile have experimental shear wave velocities and verifiable lab data. Additional data would be required to change the site class to verify the experimental data available from the USGS v_{s30} Map Viewer.

5.5. Seismic Hazard Curves

A local (site-specific) probabilistic seismic hazard analysis (PSHA) has not been performed for this project. The mean seismic hazard curve for the peak horizontal ground acceleration (PGA) and Site Class D was generated using the 2023 NSHM, as shown in Figure 59. The PGA corresponding to selected common values of return periods were interpolated from this mean hazard curve and are shown in Table 30.

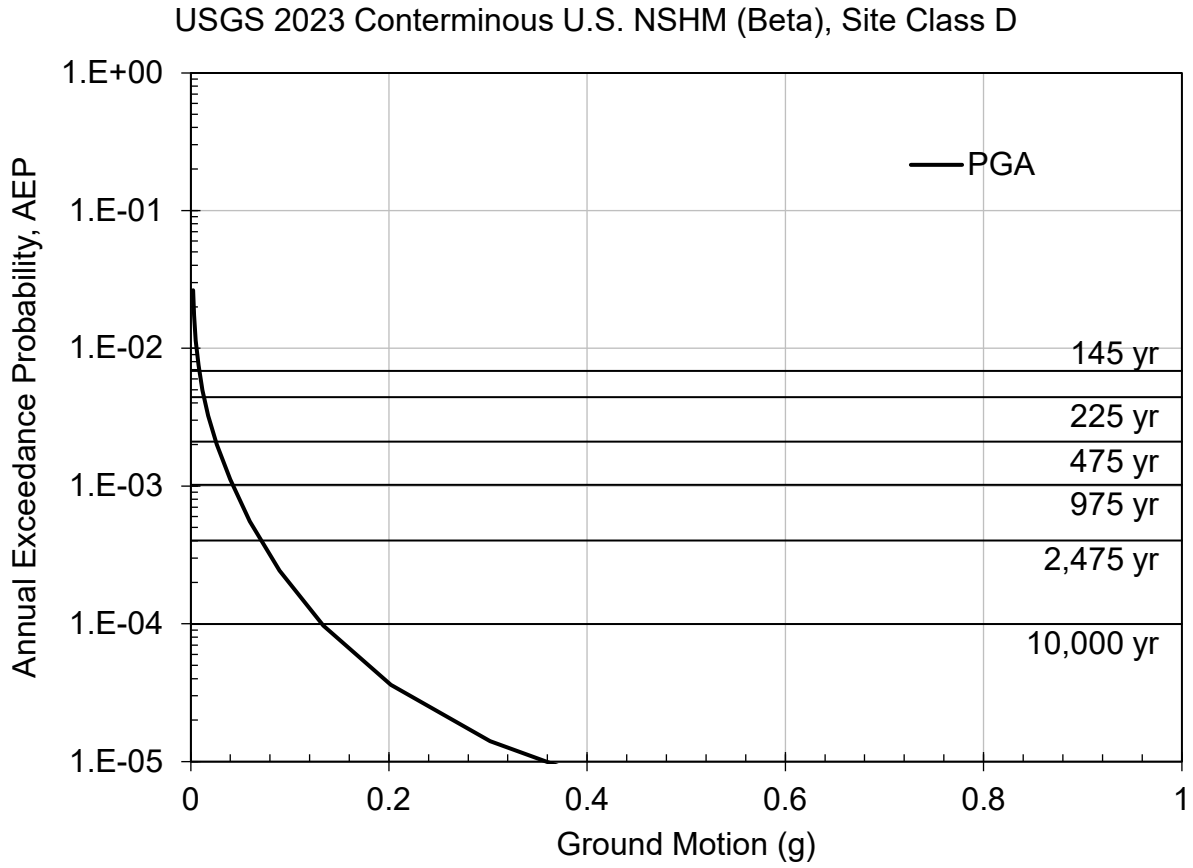

Figure 59. Seismic hazard curve for PGA and Site Class D (USGS 2023)

Table 30.
Peak horizontal ground acceleration summary for Site Class D (USGS 2023).

Return Period (years)	PGA (g)
145	0.00864
225	0.0132
475	0.0254
975	0.0419
2,475	0.0701
10,000	0.132

5.6. Disaggregation

The disaggregated seismic hazard for the PGA is shown in Figure 60 and Figure 61 using the USGS Earthquake Hazard Toolbox (https://earthquake.usgs.gov/nshmp/). Since shear wave velocity data was not available for the site, Site Class D corresponding to an average v_{s30} of 260 m/s (853 ft/s) was used to perform the disaggregation and generate these figures.

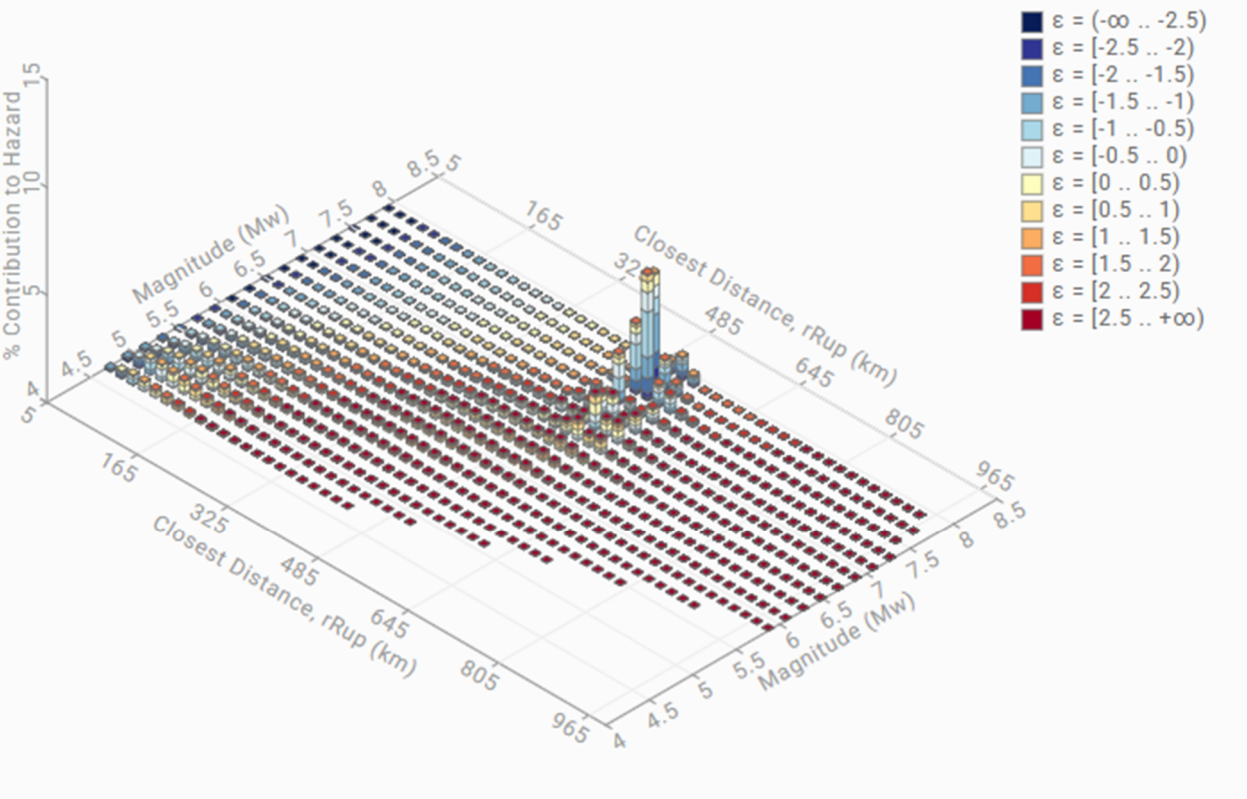

Figure 60. Probabilistic seismic hazard disaggregation for PGA and Site Class D with 1/ 145 AEP (USGS 2023)

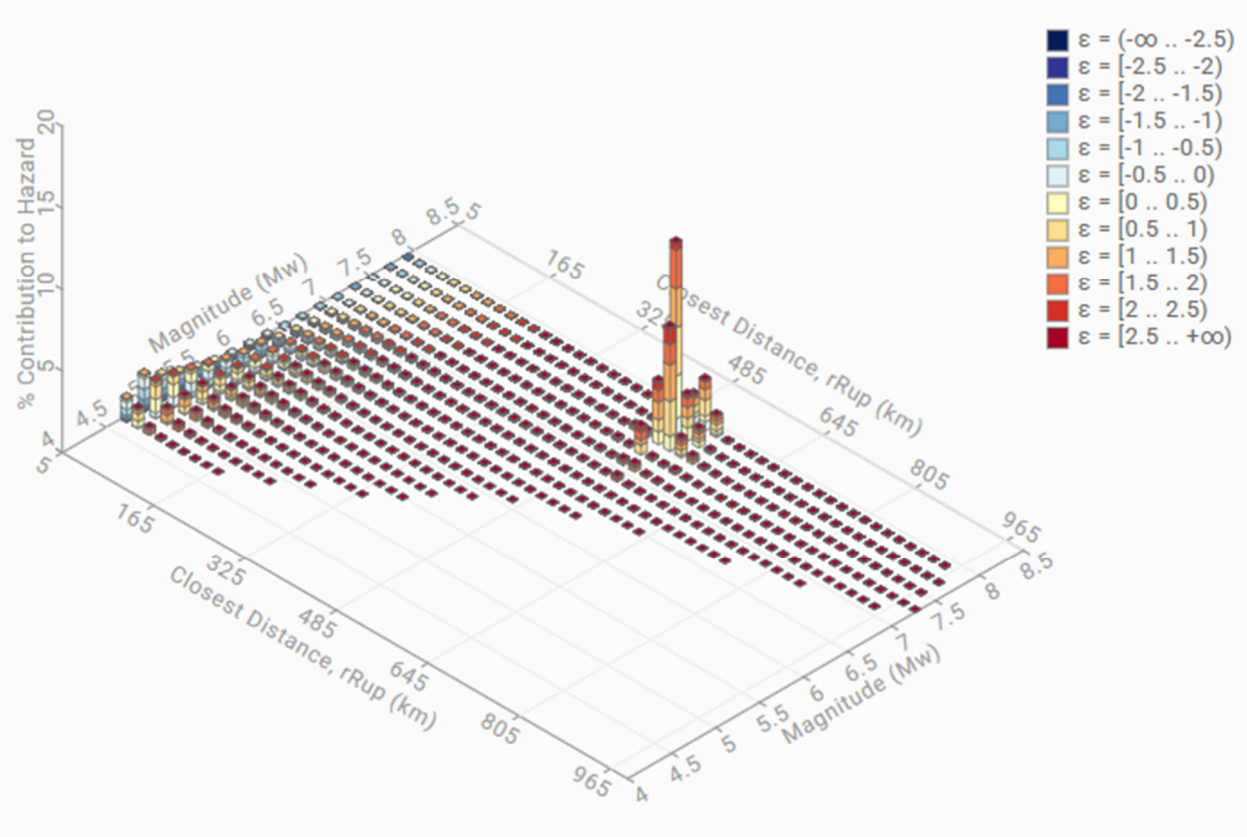

Figure 61. Probabilistic seismic hazard disaggregation for PGA and Site Class D with 1/ 2475 AEP (USGS 2023)

The disaggregation suggests that the primary contributors to the seismic hazard at the site include a M_w 7.5 earthquake on the New Madrid Seismic Zone at a distance of 511 kilometers, as well as local background seismicity ($M_w \leq 6$) at distances of less than 80 kilometers.

6. Consequences

6.1. Background

USACE has established a national standard of modeling procedures to support the estimation of consequences for breach and non-breach flood inundation scenarios for a range of loading conditions. The Modeling, Mapping and Consequence (MMC) Production Center is charged with producing scalable hydraulic levee breach models, flood inundation maps, and consequence estimations to support risk assessments. The MMC's SOP was followed by the district in the development of the hydraulic and consequence modeling for this risk assessment.

The MMC Production Center developed baseline consequence estimates for breach and non-breach inundation scenarios, uncertainty statistics for life loss estimates, and inundation mapping products. The difference between breach and non-breach consequences for a particular loading condition is the incremental consequences (i.e., those directly attributable to the levee breach for that loading condition). This information was used by the risk assessment team to assign an appropriate order-of-magnitude estimate for the risk-driving potential failure modes. Specific details and assumptions associated with the modeling, mapping, and consequences are provided with the various MMC Production Center products.

6.2. Inundation Scenarios

In order to evaluate a range of possible flood scenarios, five breach locations were included in the district's levee models. The locations and rationale for selection are summarized in Table 31, and the breach locations are shown in Figure 62.

Table 31.
Breach locations.

Breach Location	Station	Rationale for Selection
Levee Control Location (LCL)	RB 56+63	Location where significant overtopping first begins to occur
Breach Location 2 (BL2)	LB 77+43	Evaluating breach location of left bank downstream section
Breach Location 3 (BL3)	RB 47+08	Levee breach location to evaluate breach and spill into detention pond
Breach Location 4 (BL4)	RB 25+32	Evaluating right bank breach in middle of project reach in higher consequence area
Breach Location 5 (BL5)	LB 25+20	Evaluating left bank breach near upper portion of project reach

Figure 62. Breach locations.

Flood loading scenarios were developed using scaled frequency inflow flood hydrographs to produce the desired maximum water surface elevations at the Levee Control Location (LCL). The flood loading scenarios are schematically illustrated in Figure 63. Flood loading scenarios.

. The LCL maximum water surface elevation and ratio of the inflow hydrograph for each loading scenario are summarized in Table 32.

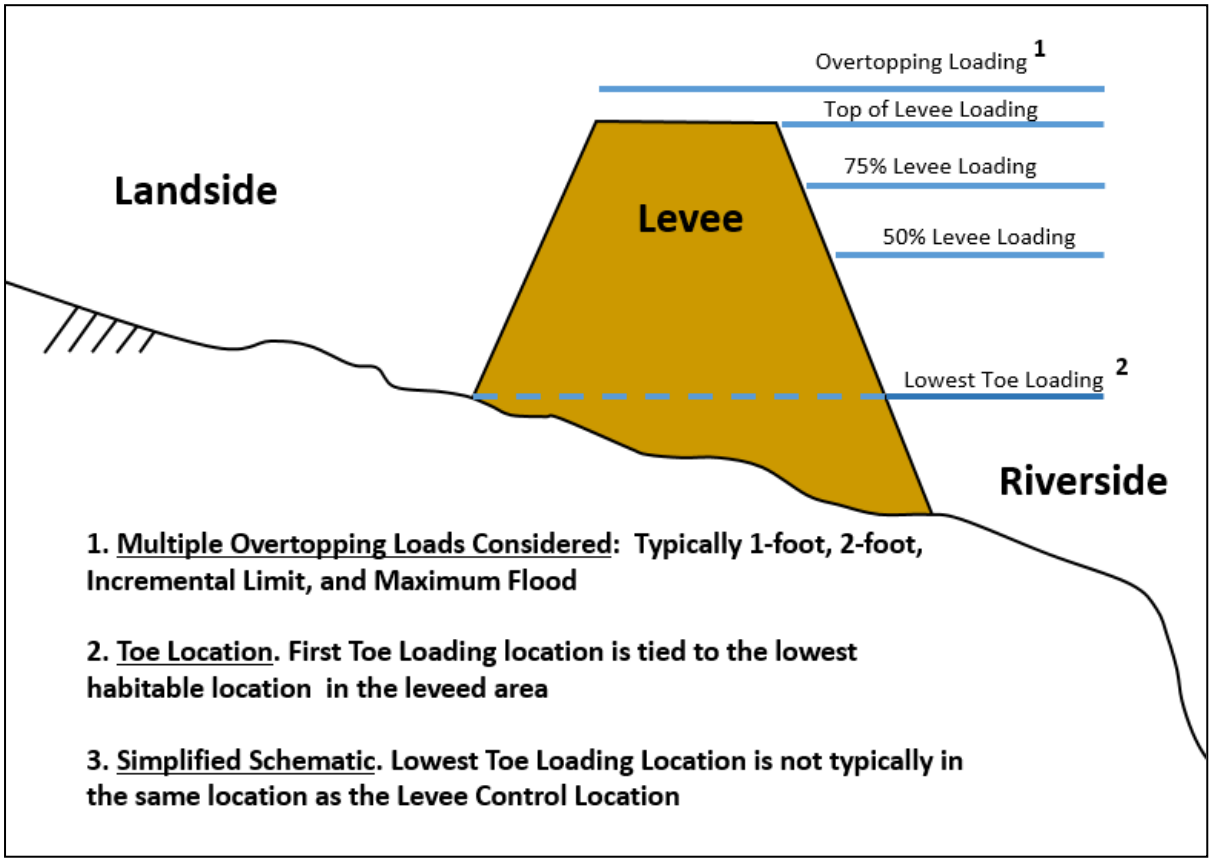

Figure 63. Flood loading scenarios.

Table 32.
Hydrologic loading event parameters.

Scenario	Water Surface Elevation at LCL (ft-NAVD88)	Ratio of Inflow Hydrograph
2-ft Overtopping	912.1	1.115
1-ft Overtopping	911.1	1.000
0.5-ft Overtopping	910.6	0.958

6.3. Breach Assumptions

The simplified physical breaching method in HEC-RAS was used to estimate breach parameters based on the physical conditions at the breach location. The method requires user-selected relationships for breach widening rate and breach downcutting rate as functions of velocity through the breach, which are used dynamically to estimate breach progression versus the actual velocity being computed through breach on a time-step by time-step basis. For this SQRA, the downcutting and widening rates were assumed the same. Erosion rates in HEC-RAS were based on a generalized descriptor of erodibility, and its associated

erodibility coefficient (k_d), which can be correlated with embankment material type (USACE 2022). It is assumed the embankment will consist of clayey sand, clayey sand with silty sand and well graded sand which corresponds to erodible materials. The assumed breach parameters are summarized in Table 33, and the estimated final breach dimensions are summarized in Table 34.

Table 33.
Simplified physical breach parameters for Sta. LB 77+43 BL2.

Velocity through Breach (ft/s)	Breach Widening Erosion Rate (ft/hr)
0	0
1	0.1607662
1.5	0.361724
2	0.6430649
3	1.446896
4	2.572259
6	5.787583
8	10.28904
10	16.07662
15	36.1724
20	64.30648
25	100.4789
30	144.6896

NOTE: Breach widening erosion rate is based on 4-ft tall erodible (k_d = 3.93 (ft/hr)/psf) embankment.

Table 34.
Simplified physical breach parameters for Sta. RB 47+08 BL3.

Velocity through Breach (ft/s)	Breach Widening Erosion Rate (ft/hr)
0	0
1	0.1492421
1.5	0.3357948
2	0.5969685
3	1.343179
4	2.387874
6	5.372716
8	9.551497
10	14.92421
15	33.57948
20	59.69685
25	93.27633
30	134.3179

NOTE: Breach widening erosion rate is based on 5-ft tall erodible (k_d = 3.93 (ft/hr)/psf) embankment.

Table 35.
Final levee breach dimensions.

Location (Station)	Loading Scenario	Final Breach Bottom Elevation (ft-NAVD88)	Final Breach Bottom Width (ft)
LB 77+43	TOL	909.57	200
RB 47+08	TOL	910.64	300

Breach dimensions and formation time for breach of a floodwall are drastically different than that of a breach of an embankment. Breach dimensions are often limited to the unsupported length of the critical floodwall section along with various other factors. In addition, floodwall failures are often considered to be brittle failures with very short breach formation times. For these reasons, a separate set of breach parameters was developed for floodwall breach at what was determined to be the critical section for floodwall instability. Due to the likely brittle nature of the breach, the breach was considered to happen instantaneously. A summary of the breach parameters for a floodwall breach are provided in Table 36.

Table 36.
Floodwall breach parameters.

Location (Station)	Loading Scenario	Final Breach Bottom Elevation (ft-NAVD88)	Final Breach Bottom Width (ft)
RB 56+63	LCL 2-ft OT	907.9	40
RB 25+32	BL4 OT	913.09	40
LB 25+20	BL5 OT	929.39	40

NOTE: Instantaneous breach formation time was assumed.

6.4. Description of Impacted Area

The project site of Merriam, Kansas sits in Johnson County and straddles Interstate 35 and is part of the Kanas City Metropolitan area. Upper Turkey Creek runs through the original downtown area of Merriam. At the lower end of the emergency planning zone, Upper Turkey Creek crosses under Shawnee Mission Parkway which is a major east-west thoroughfare and provides entrances and exits to Interstate 35. Upper Turkey Creek meanders in a north-northeast direction through Merriam before crossing under Interstate 35 near Antioch Road. The project is 1.2 river miles in length. There is a BNSF railroad track that lies between Merriam and the interstate. Merriam Drive generally parallels the interstate and crosses over Upper Turkey Creek north of downtown Merriam and ends at Shawnee Mission Parkway. From the point where Merriam Drive crosses over Upper Turkey Creek southwards, all structures to the east of the creek to the railroad are all smaller commercial and light industrial and residential to the west of the creek except for just north of Shawnee Mission Parkway where there are a few commercial structures. North of the point where Merriam Drive crosses Upper Turkey Creek all the structures in the emergency planning zone are commercial or light industrial except along the inflow to the northwest where there are some residential structures around the 51st area. The north end has some larger commercial structures than the other areas. Downtown has a large public park that is almost an entire block in size and across the street is a large farmer's market that is near Upper Turkey Creek.

6.5. Life Loss Methodology

This consequence modeling was performed using USACE's life loss and direct property damage estimation software LifeSim version 2.1.5. To determine the percentage of population at risk (PAR) within a structure that is warned and mobilized over time, several parameters are used within LifeSim to estimate the probable values of warning and mobilization percentages at each time step. These include

when hazards are identified and warnings will be issued (hazard identification and delays), how long they will take to become effective (warning diffusion), and the rate at which PAR will mobilize in response (mobilization or Protective Action Inhiation (PAI)). Figure 67 is an example breach warning and response timeline.

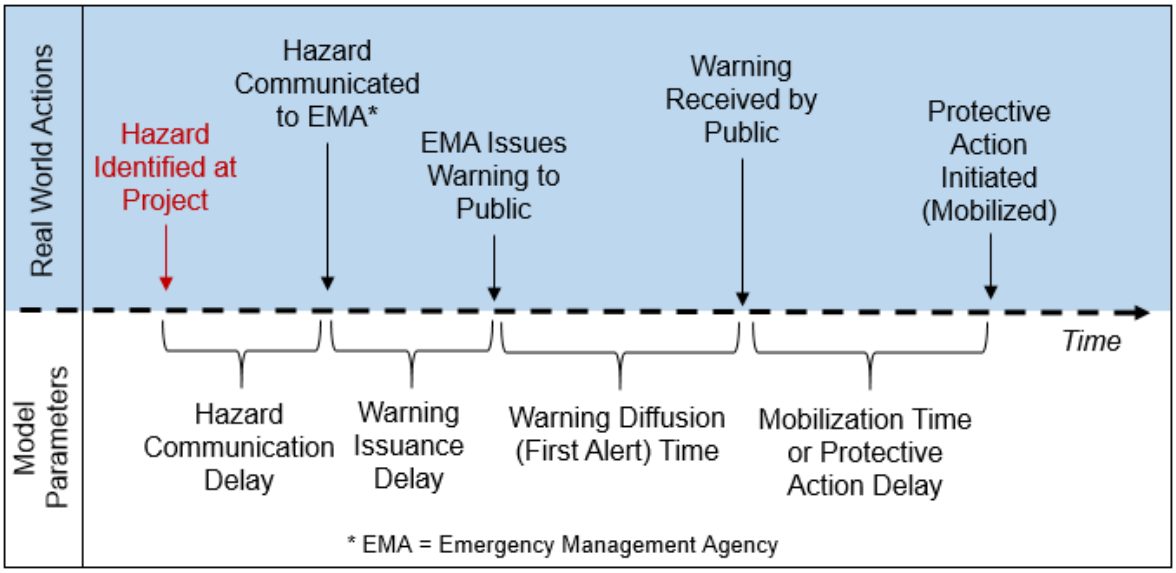

Figure 67. Warning and response timeline.

6.6. Population at Risk

Population at risk (PAR) is defined as the number of people within a leveed area that would be subject to inundation during a flood hazard event. Estimates of PAR were generated using LifeSim for breach and non-breach inundation scenarios. The estimated number of inundated structures and PAR are summarized in Table 37 and Table 38, respectively.

Table 37.
Estimated number of inundated structures.

Loading Scenario	Breach	Non-Breach	Incremental

6.7. Life Loss Model Inputs and Parameters

6.7.1. Structure Inventory

The structure inventory was developed using the USACE National Structure Inventory (NSI) version 2022 as the base dataset. The NSI is developed from estimated information regarding the locations, building types, population, values, and other relevant information for all residential, commercial, industrial, agricultural, public, and private structures across the nation. Data sources for this information include national level parcel data, Census data, building footprints, and other sources for employment and school information. The value of structures, contents, and vehicles were indexed to 2025 price levels. Additional calibration on the structure point placement was accomplished using aerial imagery and inundation maps for both high and low flow scenarios.

6.7.2. Road Network and Destination Points

Evacuation simulation was not performed.

6.7.3. Emergency Preparedness

Johnson County has an “All-Hazard Mitigation Plan” that was developed by the county’s Office of Emergency Management in 2024. Included in the plan is a section dedicated to Flood Hazards. The section on Flood Hazards discusses historical flood events in Johnson County as well as dam failure inundation. It contains a detailed list of high hazard potential dams (earthen dams) and pertinent details. Maps and flood areas and areas of dam inundation zones are included in an appendix. There is not data on levees or levee risk. The Flood Hazards section provides information about flooding and potential sources of flood risk and may be useful for citizens of Johnson County to review to help them understand their risk of being exposed to flooding.

The “All-Hazard Mitigation Plan” does discuss emergency response or operations during a flood event. The plan does not include meaningful discussion about actions that would be taken by the county’s Office of Emergency Management or the county’s Department of Public Works during a flood hazard event. The expected response during a flood hazard event is not clear, and no actionable thresholds based on flood levels are identified in the plan. Additionally, there have been no recent flood events that necessitated PAR taking protective action. Emergency response during a flood event is unknown, and generally, the PAR appears to be unaware of their risk of being exposed to flooding.

The Emergency Preparedness parameters are described in the sections below.

6.7.4. Relative Hazard Identification

The Hazard Identification time is the time at which a hazard is identified (i.e., breach) relative to when it occurs (the actual breach initiation time). Two different warning scenarios were simulated with different ranges of hazard identification time: minimal warning and ample warning.

For overtopping scenarios, warning is relative to the time that overtopping begins, not breach time. The Relative Hazard Identification Times used for this study are summarized below.

Table 39.
Relative hazard identification times.

Warning Scenario	Distribution Type	Minimum (hr)	Maximum (hr)
Minimal	Uniform	-3	0.5
Ample	None	-24	-24

6.7.5. Hazard Communication Delay

The Hazard Communication Delay is the time that it would take from when the hazard is identified to when the emergency planning zone (EPZ) representatives would be notified. For example, if a breach occurs when no one is observing the project then the emergency managers could be notified after the hazard is identified. The hazard communication delay ranged between 0.01 and 0.5 hour and assumed a uniform distribution.

6.7.6. Warning Issuance Delay

The Warning Issuance Delay is the time it takes from when the emergency managers receive the notification of the imminent hazard to when they issue the first evacuation order to the public. Although the range of possible warning issuance delay is randomly sampled from 0 and 6 hours (300 minutes) after officials are notified of the flood hazard using a Lindell distribution, it is positively skewed so that results from 0 to 1.5 hours (90 minutes) are more likely.

6.7.7. Warning Diffusion

The preset “Preparedness Unknown” warning diffusion curves were used. The curves utilize a uniform distribution, and the warning diffusion curves are sampled during each Monte Carlo iteration in LifeSim. The upper bound of the curve reaches 100% diffusion just after 1.5 hours (100 minutes), and the lower bound reaches 100% diffusion after 6 hours (360 minutes).

6.7.8. Protective Action Initiation

Protective Action Initiation (PAI) is the rate at which PAR takes action after receiving an evacuation order (warning). Unlike the warning diffusion curves, the PAI “Preparedness Unknown” curve includes a perception element as well. The perception element describes a PAR as being aware of their flood risk (Perception = Likely to Impact) or generally unaware that they are at risk of being flooded (Perception = Unlikely to Impact). The “Preparedness Unknown, Perception Unknown” curve was used for all areas.

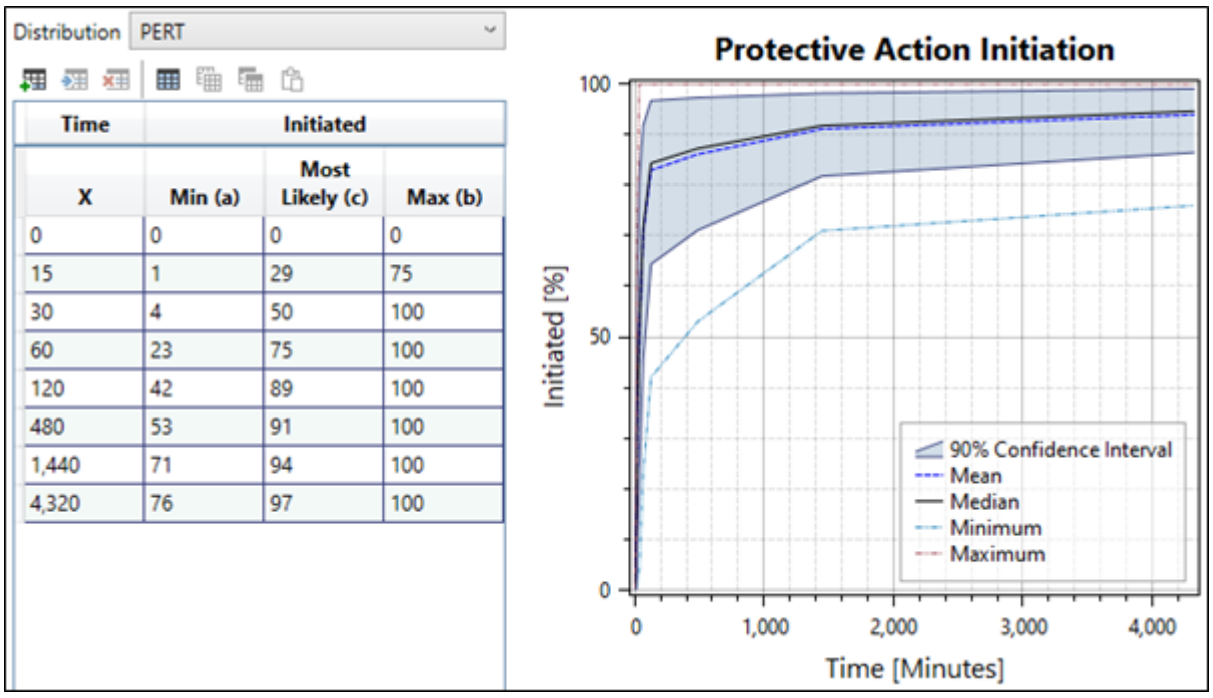

Figure 68. PAI curve for preparedness unknown, perception unknown.

6.8. Direct Life Loss

Estimates of direct life loss were generated using LifeSim for breach and non-breach inundation scenarios. LifeSim utilizes Monte Carlo uncertainty analysis, and 2,500 were performed for each scenario. The estimated direct life loss by breach location and loading scenario are summarized in the odd numbered tables Table 40 through Table 74 for minimal warning and in the even numbered tables Table 41 through Table 75 for ample warning. While the direct breach and non-breach results represent the outcome from model simulations, the direct incremental life loss results were obtained by subtracting the breach and non-breach results.

These above statistical summaries only reflect the uncertainty in the LifeSim input parameters and do not include uncertainties for breach parameters or other hydrologic and hydraulic factors. Normally, direct life loss statistics for each run are shown using box-and-whisker plots but as most of the incremental life loss numbers are zero which cannot be plotted on a log scale, the box-and-whisker plots have been omitted.

6.8.1. Life Loss on Roads

With the very low life loss in structures, the small size of the project area and the fact that the majority of the structures are commercial and/or industrial evacuation simulation was not performed.

6.9. Indirect Life Loss

Indirect life loss is based on the Impacted Population at Risk (iPAR), which is the group of people impacted by the sub-optimal conditions created by a disaster. To determine iPAR values, direct life loss numbers are removed from the initial PAR estimates. This includes the PAR comprising the population within buildings that will be flooded and those outside of the inundation zone who might evacuate due to uncertainty or other conditions as well as those who might lose power for an extended period of time. The RMC has developed guidance for estimation of indirect life loss based on research of disaster case histories. These case histories show that a reasonable estimate of indirect life loss can be based on a mean

indirect fatality rate of 0.1% of the iPAR that evacuates and 0.5% of the iPAR that does not evacuate and is exposed to flooding. This can be used to develop a screening-level estimate of indirect life loss. The table below shows the potential indirect life loss based on the iPAR for in comparison with the direct life loss estimated from LifeSim

Table 76.
Comparison of potential daytime indirect and direct incremental life loss.

Loading Scenario	Mean Evacuee Incremental Population at Risk	Mean Non-Evacuee Incremental Population at Risk	Mean Evacuee Incremental Indirect Life Loss (0.1% of Evacuee iPAR)	Mean Non-Evacuee Incremental Indirect Life Loss (0.5% of Non-Evacuee iPAR)	Mean Direct Incremental Life Loss[1]
Sta. RB 56+63 LCL 2-ft OT	343	166	0.3	0.8	1
Sta. RB 56+63 LCL 1-ft OT	339	108	0.3	0.5	1
Sta. RB 56+63 LCL 0.5-ft OT	4	0	0.0	0	0
Sta. RB 56+63 LCL TOL	4	0	0.0	0	0

NOTE: [1]Mean direct incremental life loss is for minimal warning.

Based on the indirect incremental life loss screening, it is unlikely that a detailed estimate and inclusion of indirect incremental life loss would change the estimated average incremental life loss by a half order of magnitude or more. Therefore, a detailed evaluation of indirect life loss was not performed for this SQRA.

Indirect life loss is typically caused by cardiac events or cardiovascular failure among the elderly and people with pre-existing health conditions. Other causes of indirect life loss would be power related issues that lead to carbon monoxide poisoning or failure of medical devices and life loss during evacuation not caused by drowning.

6.10. Economic Losses

Economic considerations help inform risk management decisions. Direct economic losses considered in this SQRA included include direct property damages, and levee repair or replacement costs.

6.10.1. Direct Property Damage

An inventory of downstream property directly damaged by the inundation was developed using the structure inventory described in Section 6.7.1 which contains information for residential, commercial, industrial, agricultural, public and private structures as well as data for essential facilities such as hospitals, clinics, fire stations, police stations, emergency operation centers, schools and universities.

Direct property damage including structure, content, and vehicle damage was estimated in LifeSim using standard depth-percent damage curves specific to each structure occupancy type and structure stability curves which evaluate damage caused by combined depth and velocity.

The area near the project is predominantly commercial and light industrial businesses and these are the structures are getting damaged. The estimated mean direct property damage is summarized in Table 77.

Table 77.
Estimated mean direct property damage.

NOTE: FY 2025 price level

6.10.2. Levee Embankment and Floodwall Repair or Replacement Costs

As this is a design SQRA and the levee has not been through 65% design yet, the costs are not firm enough that it would make sense to estimate replacement costs at this point.

7. Risk Assessment

7.1. Potential Failure Mode Analysis

A potential failure mode (PFM) is a unique set of conditions and/or sequence of events that could result in failure. For dam and levee safety risk assessments, failure generally results in breach or the formation of a gap in the dam or levee system through which water may flow uncontrolled onto the downstream flood plain or adjacent leveed area. It is characterized by the "sudden, rapid, and uncontrolled release of impounded water" as defined in FEMA P-93 (FEMA 2004), and FEMA P-1025 (FEMA 2015) expanded the definition of failure to include "liquid-borne solids" like mine tailings and dredge spoils.

A potential failure mode analysis (PFMA) is a facilitated process of identifying and fully describing PFMs. It is based on a team's understanding of the project's vulnerabilities from a review of existing data and conditions. The facilitated PFMA and SQRA were performed on 08-11 Month 2025. Additional meetings were held virtually after the in-person meeting to discuss the risk drivers and elicit. The SQRA team and their roles are provided in Table 78.

Table 78.
PFMA team.

Name	Organization/Office	Discipline/Role
Alex Nelson, P.E.	Levee Safety Center	Hydraulic Engineer (Facilitator)
Axel Montalvo-Bartolomei, P.E.	Levee Safety Center	Geotechnical Engineer (Co-facilitator)
Courtney Forsythe	Kansas City District	Tech Lead / Civil Engineer
Conner Szarwinski	Kansas City District	H&H Engineer
Luke Augustine	Kansas City District	Geotechnical Engineer
Brandon Harmon	Kansas City District	Geologist
Paul Muller	Kansas City District	Structural Engineer
Devin Smith	Kansas City District	Economist
Kailey Jones	Kansas City District	Project Manager
Derek Jenson	Kansas City District	Geotechnical Engineer
Forrest Pritt	Kansas City District	Civil Engineer
Gregory Wachman	St. Paul District	Geotechnical Engineer

Advance preparation includes collecting and reviewing the background and performance data, site characterization, hydrologic and seismic hazards, hydraulic and consequence modeling, and performing any screening or limited supporting analysis. Prior to the PFMA, a site visit was performed to help the team look for clues as to how the dam or levee system and appurtenant structures may be vulnerable to failure.

A site visit and review of background data was initially conducted followed by brainstorming of PFMs by the SQRA team. Table 79 provides the list of PFMs brainstormed by the SQRA team. PFMs related to sabotage or terrorism were beyond the scope of this risk assessment. From the list of brainstormed PFMs resulting in breach and uncontrolled release, the SQRA team identified the PFMs judged to be risk drivers. PFMs that were judged to be non-risk drivers were excluded from further consideration, and the rationale is provided in Appendix A.

Table 79.
Potential failure modes.

Potential Failure Mode	Risk Driver?	Description
PFM 01	Yes	Overtopping breach of the levee
PFM 02	No	Overtopping breach of the floodwall
PFM 03	No	Concentrated leak erosion through the embankment between construction lifts
PFM 04	No	CLE along differential settlement
PFM 05	No	CLE along levee/wall/bridge interfaces
PFM 06	No	Flap gates stuck open resulting in backflow (for pipe >36", assuming one flap gate per pipe)
PFM 07	Yes	Global instability of the levee
PFM 08	No	Global instability of the I-wall
PFM 09	Yes	Global instability of the T-wall
PFM 10	No	Local instability of the I-wall
PFM 11	No	Local instability of the T-wall
PFM 12	No	Internal migration into the storm sewer
PFM 13	Yes	Internal migration into sanitary sewer
PFM 14	No	Internal erosion out of sanitary sewer
PFM 15	No	CLE along a pipe
PFM 16	No	CLE or BEP through the levee foundation
PFM 17	No	CLE or BEP through I-wall foundation
PFM 18	No	CLE or BEP through T-wall foundation
PFM 19	No	Instability of limestone wall leads to levee instability
PFM 20	No	Instability of limestone wall leads to I-wall instability
PFM 21	No	Instability of limestone wall leads to T-wall instability
PFM 22	No	Seismic instability of levee or wall
PFM 23	No	Riverine erosion of levee toe or levee face
PFM 24	No	Riverine erosion of T-wall foundation
PFM 25	No	Riverine erosion of I-wall foundation
PFM 26	No	Failure of Johnson Bridge due to uplift
PFM 27	No	Debris impact failure of wall/bridge
PFM 28	No	Pedestrian bridge fails and impacts wall/bridge/levee
PFM 29	No	Channel erosion undermines limestone wall and fails levee/wall
PFM 30	No	Structural failure of I-wall
PFM 31	No	Structural failure of T-wall
PMF 32	No	Vehicle impact failure of I-wall
PMF 33	No	Tree next to the floodwalls/levees topples and leads to instability
PMF 34	No	Wind-wave levee erosion
PMF 35	No	Internal erosion out of pressurized pipe
PMF 36	No	Bridge construction leads to increased water levels for existing conditions
PMF 37	No	Flap gate stuck closed leads to excessive ponding

7.2. Risk Assessment

A semi-quantitative risk assessment (SQRA) is a facilitated process of making order-of-magnitude estimates of likelihood of failure and average incremental consequences. It is based on limited numerical data and judgment. The facilitated SQRA was performed using the team listed in Table 78.

Risk drivers from the PFMA were fully developed and semi-quantitatively evaluated. This includes a complete description of the failure mechanism from initiation to failure, nature of the failure (e.g., breach characteristics) and consequences, event tree, pertinent background and performance data, likelihood factors, estimated likelihood of failure and associated consequences, intervention, plotting on a risk matrix, and any sources of significant uncertainty in the estimates. Lastly, any recommendations for risk-reduction actions, instrumentation and monitoring, additional data, or analysis were discussed. Table 80 summarizes the PFMs judged to be risk drivers.

Table 80.
Risk-driving potential failure modes.

Potential Failure Mode	Description
PFM 01	Overtopping breach of the levee
PFM 07	Global instability of the levee
PFM 13	Internal migration into sanitary sewer

The incremental risk (due to failure) considers likelihood of failure and incremental consequences. The likelihood of failure is a function of both the likelihood of the loading condition that could lead to failure (i.e., critical loading) and the likelihood of failure given the loading condition (i.e., conditional probability of failure or system response probability). During the SQRA, order-of-magnitude estimates were made for both likelihood of failure and incremental consequences for each risk-driving potential failures mode. The evaluation of each risk-driving PFM was documented as well as any sources of significant uncertainty.

7.3. PFM 01: Overtopping breach of the levee

7.3.1. Description

A flood occurs on Turkey Creek with a flow greater than 19,000 cfs, AEP of 7.65E-03 (1/130-year) event. Efforts to raise the levee are unsuccessful and the levee system begins to experience balanced overtopping. Overtopping of a large portion of both floodwalls and levee sections occurs almost immediately after overtopping starts at the levee control location (LCL). A 10-feet tall levee was evaluated as a representative section. As flows increase on Turkey Creek to 0.5-feet of overtopping AEP of 5.62E-03 (19,800 cfs, ~1/180 AEP), 1-foot of overtopping AEP of 4.02E-03 (21,300 cfs, ~1/250 AEP), and the 2-foot overtopping AEP of 2.11E-03 (25,800 cfs, ~1/470 AEP) the overtopping flow velocity is sufficient to erode and remove the landside grass cover. Knick points are created at the levee toe slope change, and erosion begins on the landside levee slope. The erosion channel deepens and widens, resulting in the formation of head-cuts on the landside slope, and rill development occurs. Overtopping is of sufficient duration such that progressive headcutting advances through the crest of the levee. This results in a rapid uncontrolled release of water into the leveed area with associated loss of life and economic consequences. An event tree of this failure description is shown in Figure 75 along with a location of a potential 10-foot tall levee overtopping in Figure 69, and details of the embankment section in Figure 70.

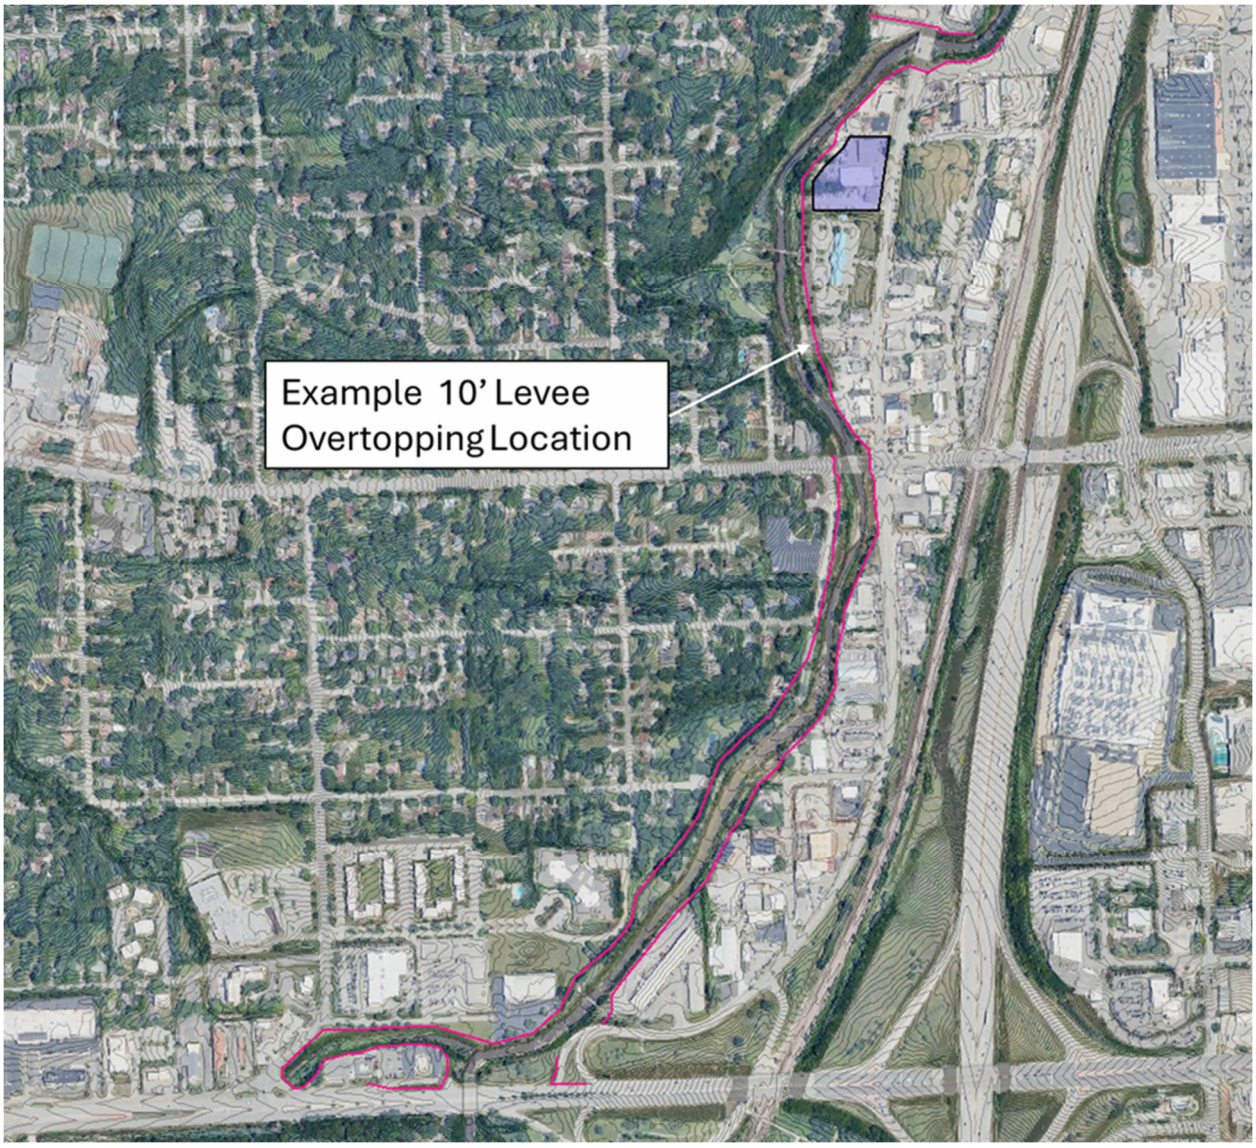

Figure 69. Example overtopping location of a 10-foot levee section.

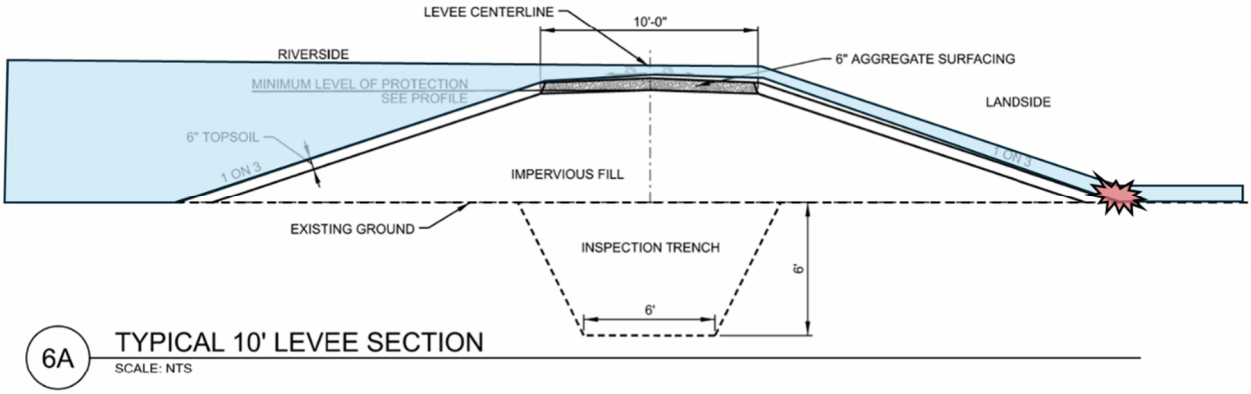

Figure 70. Overtopping at a 10-foot-tall levee section.

7.3.2. Background

The typical levee height is around 10 feet tall but can be as low as 4 feet or as tall as 14 feet in some sections. The levees are designed with a 10 to 14-foot top width. Some of the levee crowns will be paved with asphalt to replace existing paved trails. Riverside and landside slopes are to be 1V:3H and will have planted and established grass cover. Stability berms and sand drains are tentatively included in the design in some areas but are expected to be removed as part of the risk informed design changes, so they were not factored in to the elicitation of this PFM. The impervious fill is to consist of lean clays and/or low plasticity silt, which could be considered moderately resistant to erosion. A borrow area has not yet been identified, though the detention pond is a potential source pending HTRW.

Overtopping durations and velocities were analyzed for this failure mode for the three overtopping depths outlined below. Table 81 shows overtopping velocities at the levee section along with overtopping durations previously estimated in Chapter 4 for each loading scenario along with the peak elevations at the LCL. These durations were used for the evaluation of PFM 01 at an example 10-foot-tall levee section. The overtopping velocities were determined in a spreadsheet using weir equations, normal depth, and critical depth equations. The normal velocity is computed using the Manning's equation, after computing the normal depth by an iterative process. The velocities considered from the spreadsheet are the normal depth velocities. Overbank velocities in the channel can influence overtopping velocities and are fairly high in the channel, but are lower along the landside embankment, around 5-6 ft/sec.

Table 81. Overtopping velocities and durations at the 10-foot levee section.

MMC Loading Scenario	Overtopping Velocity (ft/s)*	Total Overtopping Duration	Duration Above Toe
0.5 ft OT	8.3	0.5 hrs	1 hr
1 ft OT	12.6	1 hr	1.5 hrs
2 ft OT	18.7	1.5 hrs	1.67 hrs

*Velocities are estimated with a typical 10-foot levee section since the LCL is located at a short floodwall section

Velocities on the 1V:3H levee slope likely exceed 8 ft/sec for overtopping depths greater than or equal to 0.5 feet. Though this can depend on the height of the levee section. Levee heights vary from 4- to 10-feet with the current design iteration. Figure 71 shows the estimated distance from the riverside crest to develop peak velocities. It should be noted that overtopping depths of 2-feet lead to widespread

overtopping of almost the entirety of the flood protection system. Interior depths would be sufficient that flow would enter back into the channel on the downstream end of the project area by way of landside overtopping. Stage-frequencies were estimated at the LCL and used for PFM 01 given that the levee experiences balanced overtopping throughout the levee system immediately after incipient overtopping. This is shown in Table 82.

Table 82. Stage-Frequency at LCL location (Channel STA 65+40)

Loading Scenario	AEP	Elevation (ft, NAVD88) at LCL (Channel STA 65+40)
1,000	1.00E-03	913.15

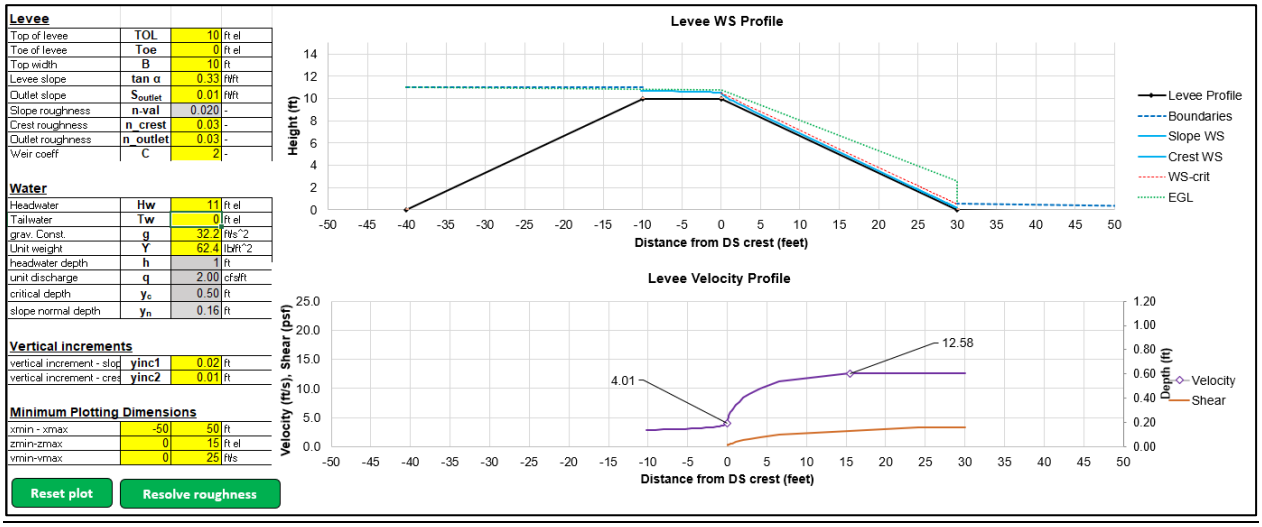

Figure 72. Estimated overtopping velocities for 1-ft OT depth at 10-ft levee section.

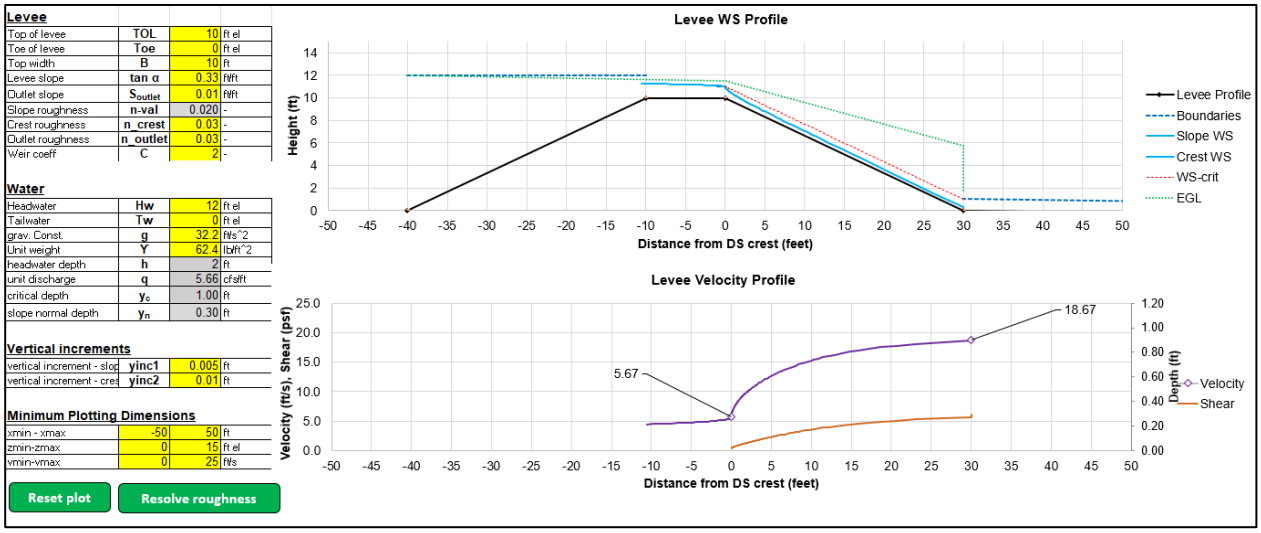

Figure 73. Estimated overtopping velocities for 2-ft OT depth at 10-ft levee section.

7.3.3. Performance

The levee system is in the design phase, and thusly, has no performance history.

7.3.4. Intervention

Intervention is unlikely to occur during an extreme flood event. The Turkey Creek watershed does not have flood forecasting capabilities such as those available through the National Weather Service. The upstream drainage area of Turkey Creek is approximately 12 square miles and heavily urbanized. Storm events of sufficient magnitude result in very flashy floods that leave little time to prepare or respond to. Rate of rise of the channel for overtopping events are likely to exceed 20 feet/hour With the total out of bank duration lasting only an estimated 3-4 hours. Drainage structures are proposed to be fully passive,

and no closure structures exist in the design because of the little warning time and flashiness of the system.

7.3.5. Likelihood of Failure

Table 83 summarizes the likelihood factors that make the PFM more likely or less likely to lead to failure.

Table 83.
Likelihood factors for PFM 1.

More Likely (Adverse) Factors	Less Likely (Favorable) Factors
• Sand drain exiting at the landside toe will be more vulnerable to erosion once the vegetation and top soil is removed. This is at the location of highest landside slope velocities and may lead to faster headcut progression.	• **Short duration of expected overtopping flows (less than 2 hours for up to 2 feet of peak overtopping depth) may be insufficient to initiate or progress erosion to failure.**
• Unsuccessful intervention is likely due to the flashy nature of flooding	• Lean clay and low plasticity silt may be unlikely to erode tens of feet to fully breach the levee in the short duration of overtopping.
• Consequence warning will be minimal as there are no forecasting capabilities for this creek.	• Levee is in a high visibility area so maintenance of vegetation or animal burrows should be dealt with regularly.
• Landside slope velocities of 8 or more ft/s are likely to erode clays and silts, if vegetation has been removed.	• Vegetation is likely in average or good condition and will likely withstand short durations of low overtopping depths without failure.
• Debris blockage at the bridges or debris/vegetation growth in the channel can result in increased overtopping depths further upstream on the project. If channel maintenance is deferred, further sedimentation and debris accumulation can continue to increase stages.	• For greater depths of overtopping (e.g., 2 feet), overtopping is occurring along most of each levee segment which would build tailwater making failure less likely and incremental consequences from a breach minimal.
• No features present to arrest the erosion in the levee.	•

NOTE: Key factors are shown in **bold**.

The annual probability of failure was estimated between 3E-04 and 3E-03 (with and without intervention)

7.3.5.1. Rationale

7.3.5.1.1. 0.5 ft of OT

Overtopping occurs in numerous locations at 0.5 feet of depth at the LCL, including levee and floodwall sections. The 10-foot levee section used for the risk assessment will experience an estimated overtopping velocity of 8.3 ft/s on the landside slope. Grass stripping is very unlikely to unlikely because of the short overtopping duration with the assumption of established and good vegetation cover. The total overtopping duration of 0.5 hours. Knickpoints are expected to be the slope change at the landside toe.. Lean clays and low plasticity silts along with potentially asphalt paved crests are expected to slow headcutting. Intervention is not expected to occur due to the flashiness of the system with no established flood forecasting for the watershed. Additionally, there are no known low spots with the levee being in design, so armoring or raising of the system would need to occur for the entire alignment, which includes 0.8 miles of levee between the left and right banks.

7.3.5.1.2. 1 ft of OT

A 1-foot overtopping depth would lead to significant portions of the levee system to be overtopping. Overtopping duration is 1 hour with a peak overtopping velocity of 12.6 ft/s. The higher velocities are unlikely to neutral to strip the grass cover, again because of the short overtopping durations. Knickpoints are expected to be the slope change at the landside toe. Lean clays and low plasticity silts along with potentially asphalt paved crests are expected to slow headcutting. Intervention is not expected to occur due to the flashiness of the system with no established flood forecasting for the watershed.

7.3.5.1.3. 2 ft of OT

At 2 feet of overtopping, the entire alignment is overtopping. Peak overtopping velocities are estimated to be 18.6 ft/s with a duration of 1.5 hours. Overtopping velocities are likely to erode grass cover and initiate headcutting at a knickpoint of the landside levee toe. Progression of headcut all the way to breach is unlikely due to the short duration and development of tailwater.

The annual probability of failure (APF) was estimated from a quantitative risk analysis (QRA) using an event tree approach. The overtopping scenarios discussed in Chapter 6 define a continuous loading relationship between peak water surface elevation and AEP. Z-variate interpolation was used to calculate the AEP for peak water surface elevations between those that define the relationship. The conditional probability of failure was estimated as a function of overtopping depth by team elicitation.

7.3.5.1.4. Nodal Estimates for 0.5 ft of OT

The 0.5-foot overtopping loading contained has an AEP of 5.56E-03 (1/180-year). The incipient overtopping location is a floodwall section at channel station 65+40 on the right bank. Given the balanced overtopping configuration of the levee profile, the 0.5-foot overtopping AEP was considered the same at the example section of 10-foot-tall levee. Unsuccessful intervention is virtually certain (1.0) as there is no flood forecasting capability for the Turkey Creek watershed, and the general flashiness of the system allows for little to no time to prepare for flood fighting. Flooding along Turkey Creek occurs within an hour of heavy rainfall given the small upstream drainage area, and flooding duration is less than 3 hours. Good grass cover on the levee slopes will be included in the specifications as part of the design which would offer some erosion resistance. The landside slopes will be designed to 1V:3H, producing peak velocities of 8.3ft/s. Slope protection failing was found to be very unlikely to unlikely (0.05) given the short duration of overtopping of 0.5 hours. The most likely headcut initiation location was determined to be at the landside levee toe at the slope change. Velocities are sufficient to initiate a headcut, but duration may not be sufficient to sustain a headcut all the way to the crest. A neutral value (0.5) was given to headcut initiation. No non-erodible features are present in the levee cross section to prevent or arrest erosion of the levee crest, so continuation was determined to be virtually certain (1.0). Breach was determined to be between very unlikely and unlikely (0.05) to progress fully through the embankment and crest with a 0.5-hour overtopping duration.

7.3.5.1.5. Nodal Estimates for 1 ft of OT

The 1-foot overtopping loading condition has an AEP of 4E-03 (1/250-year) at the LCL. Given the balanced overtopping configuration of the levee profile, the 1-foot overtopping AEP was considered the same at the example section of 10-foot-tall levee. Unsuccessful intervention is virtually certain (1.0) as there is no flood forecasting capability for the Turkey Creek watershed, and the general flashiness of the system allows for little to no time to prepare for flood fighting. Good grass cover on the levee slopes will be included in the specifications as part of the design which would offer some erosion resistance. The landside slopes will be designed to 1V:3H, producing peak velocities of 12.6 ft/s. Slope protection failing

was found to be unlikely to neutral (0.25) given the shorter duration of overtopping of 1 hour, but higher velocities than the 0.5 ft loading. The most likely headcut initiation location was determined to be at the landside levee toe at the slope change. Velocities are sufficient to initiate a headcut, but duration may not be long enough after failure of the slope protection. A neutral value (0.5) was given to headcut initiation. No non-erodible features are present in the levee cross section to prevent or arrest erosion of the levee crest, so continuation was determined to be virtually certain (1.0). Breach was determined to be between very unlikely to neutral (0.25) to progress fully through the embankment and crest with a 1-hour overtopping duration.

7.3.5.1.6. Nodal Estimates for 2 ft of OT

The 2-foot overtopping loading contained has an AEP of 2.13E-03 (1/470-year) at the LCL. Given the balanced overtopping configuration of the levee profile, the 2-foot overtopping AEP was considered the same at the example section of 10-foot-tall levee. Unsuccessful intervention is virtually certain (1.0) as there is no flood forecasting capability for the Turkey Creek watershed, and the general flashiness of the system allows for little to no time to prepare for flood fighting. Good grass cover on the levee slopes will be included in the specifications as part of the design which would offer some erosion resistance. The landside slopes will be designed to 1V:3H, producing peak velocities of 12.6 ft/s. Slope protection failing was determined to be likely (0.9) due to the significant overtopping velocities. The most likely headcut initiation location was determined to be at the landside levee toe at the slope change. Headcut initiation was given a value of likely (0.9), again because of the high velocities. No non-erodible features are present in the levee cross section to prevent or arrest erosion of the levee crest, so continuation was determined to be virtually certain (1.0). Breach was determined to be between very unlikely to neutral (0.3) to progress fully through the embankment and crest with a 1.5-hour overtopping duration.

The system response curve is tabulated in Table 84 and portrayed in Figure 74 with and without intervention. Linear interpolation was used to calculate the conditional probability of failure for peak water surface elevation between those that define the system response curve. The APF for overtopping with breach is estimated to be at most 5.1E-04 failures per year with and without intervention from the 2-foot overtopping scenario. Therefore, the estimated APF is between 3E-04 and 3E-05 failures per year with and without intervention. Calculations are provided in Appendix C.

Table 84. Overtopping system response curve for PFM 01.

Overtopping Depth (feet)	System Response Probability (with and without intervention)	APF (with and without intervention)
0.0	0	0
0.5	0.001	6.9E-06
1.0	0.031	1.3E-04
2.0	0.240	5.1E-04

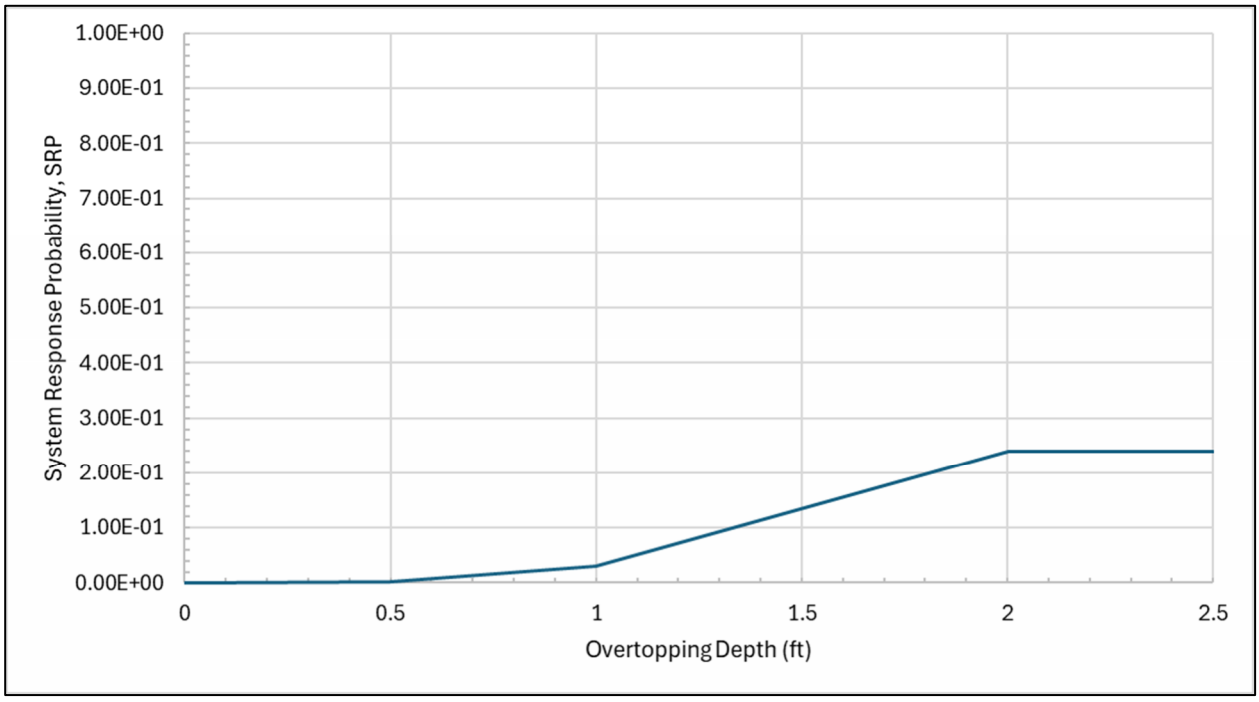

Figure 74. System response curve for PFM 01 (with and without intervention).

7.3.5.2. Uncertainty

There is major uncertainty in the hydrology due to a lack of consistent flow records anywhere along Turkey Creek, as previously discussed. The gage at Johnson Drive within the project area is not a USGS gage and does not record flow data, nor does it have an accompanying stage-discharge rating curve. Thus, an RMC-BestFit, flow frequency analysis is not possible to perform at this location. Instead, frequency flows (inflows) were developed using HEC-1, a hydrologic modeling software during the feasibility study, with Atlas 14 frequency precipitation depths for the 24-hour storm that would then be routed through the developed hydraulic model. Uncertainty is present in the duration and distribution of the frequency storm used in HEC-1 as this is often subjective and/or based on regional trends. Additionally, the Turkey Creek watershed is heavily urbanized and fully accounting for underground stormwater network routing and overland runoff is nearly impossible without significant additional data and time, which is out of the scope of this study.

There is major uncertainty in the hydraulic modeling because a lack of useable calibration data. Despite the base HEC-RAS model being set up for 2D rain-on-grid modeling, there are significant limitations to its ability to route storm network flow which could drastically affect routing timings and therefore affect peak flow magnitude, timing, and hydrograph shapes in the Turkey Creek channel. Using historical gridded precipitation to calibrate historic storms may lead to unrealistic calibration parameters by compensating for the stormwater network routing limitations. For this reason, best engineering judgement was used for selection of the calibration parameters while leaning towards more conservative modeling assumptions to account for hydraulic uncertainty in the design. Recent considerations were given to simulating 2017 storm events in the HEC-1 model, if possible, to compute inflows for the current set up of the HEC-RAS model and calibration efforts. But this was beyond the time allotted and scope of this SQRA. Highwater marks from the 2017 flood are also available for calibration purposes should these

historic inflows be computed in the future. But again, there is significant uncertainty in the historic flows and if they are representative of current conditions.

7.3.6. Incremental Life Loss

The average incremental life loss was estimated between 3 and 30.

7.3.6.1. Rationale

The mean incremental life loss estimates use the 0.5-foot OT (0 day/0 night), 1-foot OT (1 day/0 night), and 2-foot OT (1 day/0 night) life loss estimates for minimal warning. Minimal warning was used due to a lack of flood forecasting capability in the Turkey Creek watershed and the very flashy nature of the system. Evacuation routes are available in each section of the left and right bank levee systems both by vehicle and by foot due to the small size of the leveed area. The leveed areas are primarily commercial and industrial which leads to little nighttime population at risk. Historic floods show no recorded life loss along the upper portions of Turkey Creek. Generally, life loss has occurred in adjacent urban watersheds during the same storm events.

The incremental life safety risk was estimated from a QRA, building on the branches described for APR above. The overtopping scenarios discussed in Chapter 6 define a continuous consequence relationship between peak water surface elevation and incremental life loss. The breach life loss for 1-foot of overtopping was assumed for incipient overtopping (at top of levee) due to potential differences in breach parameters and warning assumptions associated with the breach prior to overtopping scenario at top of levee (100% levee height loading). Linear interpolation was used to calculate the incremental life loss for peak water surface elevations between those that define the relationship. Average incremental life loss estimates were weighted by time-of-day exposure: 0.45 for daytime and 0.55 for nighttime. The incremental flood limit, where breach and non-breach life loss are equal and increment life loss is zero, was estimated by the MMC to occur at an overtopping depth of 0.5 ft (5.62E-03 AEP).

The average annual incremental life loss (AALL) was estimated to be 1.8E-04 lives per year with and without intervention. The weighted average incremental life loss per failure ($\bar{N}$) was calculated by dividing the AALL by the APF resulting in 0.2 lives per failure with and without intervention. Therefore, the estimated average incremental life loss is between 0.1 and 1 lives per failure with and without intervention. Calculations are provided in Appendix C.

7.3.6.2. Uncertainty

Discuss any sources of significant uncertainty related to the average incremental life loss which includes the hydraulic modeling (e.g., breach parameters and flood characteristics) and consequence modeling (e.g., emergency preparedness, warning and evacuation, etc.).

7.3.7. Incremental Economic Cost

The average incremental economic cost was estimated between $300K and $3M.

7.3.7.1. Rationale

The incremental economic risk was estimated from a QRA, building on the branches described for APF above. The overtopping scenarios discussed in Chapter 6 define a continuous consequence relationship between peak water surface elevation and incremental economic cost. The breach economic cost for 1 foot of overtopping was assumed for incipient overtopping (at top of levee) due to potential differences in

breach parameters associated with the breach prior to overtopping scenario at top of levee (100% levee height loading). Linear interpolation was used to calculate the incremental economic cost for peak water surface elevations between those that define the relationship. The incremental flood limit, where breach and non-breach economic cost are equal and increment economic cost is zero, was estimated by the MMC to occur at an overtopping depth of 0.5 ft (5.62E-03 AEP).

The average annual incremental economic cost (AAEC) was estimated to be $1E03 per year with and without intervention. The weighted average incremental economic cost per failure ($\bar{\$}$) was calculated by dividing the AAEC by the APF resulting in $1.96E+06 per failure with intervention and without intervention. Therefore, the estimated average incremental economic cost is between $300K and $3M per failure with intervention and without intervention. Calculations are provided in Appendix C.

7.3.7.2. Uncertainty

Discuss any sources of significant uncertainty related to the average incremental economic cost which includes the hydraulic modeling (breach parameters and flood characteristics) and consequence modeling (limitations of structure inventory, repair costs, etc.).

7.4. PFM 7: Global instability of the levee

7.4.1. Description

A flood event with an AEP of 1/130 loads the levee embankment. The water in the Upper Turkey Creek reaches the top and loads the riverside slope. This condition leads to an increase in the shear stress of the embankment and the soils underneath. The increase in pore pressures leads to a decrease in the shear strength of the soils. An initial slope instability failure occurs on the landside slope with a slip surface that goes through the embankment and blanket. The severity of this initial slope instability could be sufficient to lower the crest and to breach the embankment. If the initial slope instability is not severe enough to lower the crest, the levee could still resist the loading. However, the embankment is not designed with a zone of higher strength that could arrest retrogressive instability. Intervention to prevent stability failures will not be possible. The load on the levee due to the flood causes stability failures to advance through the embankment, lowering the crest, and leading to uncontrolled release of water into the protected area.

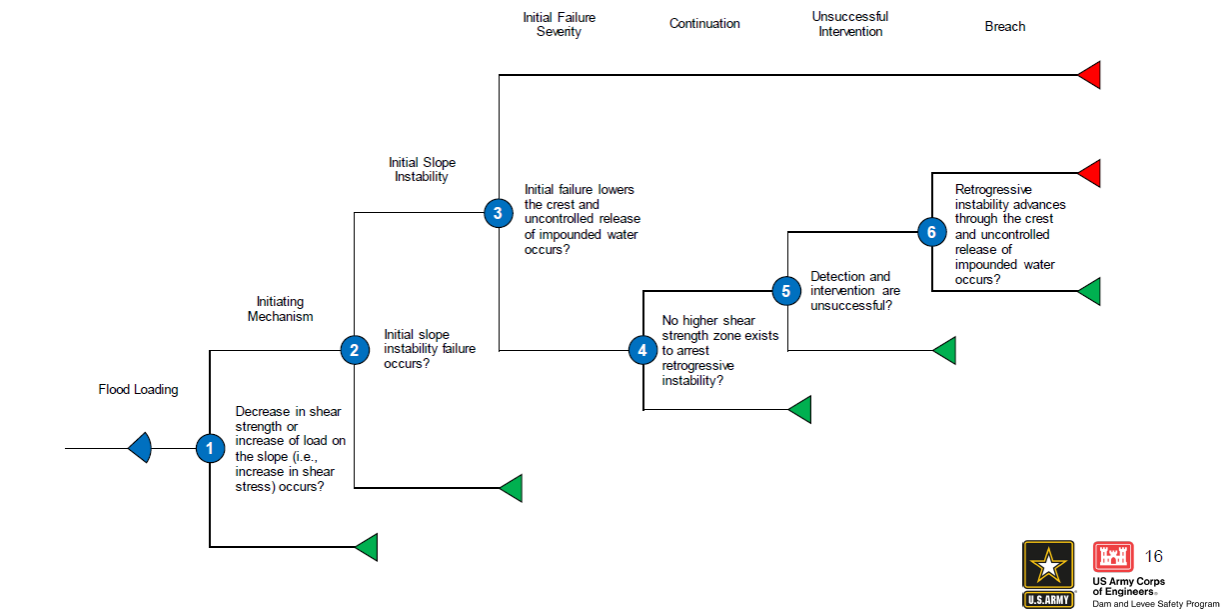

Figure 75. Event tree for PFM 07.

7.4.2. Background

The project has in its current design areas where earthen embankment levees will be used for flood control along both banks. Floodwalls are proposed for areas where there is no sufficient space for levees. The levees will consist of fine-grained materials such as lean clays (CL) or low plasticity silts (ML) in accordance with ASTM D2487. A borrow site has not been identified. The material will likely be acquired from a local commercial borrow source. Fine-grained soils with high plasticity and sandy soils will not be used. The areas where the levees will be constructed will be cleared, grubbed and stripped in preparation to place the fill. The levee will be compacted with equipment suitable for the type of material that will be used. The slopes of the levees will be 1V:3H for levees that exceed 5 feet in height, whereas levees that are less than 5 feet tall will use 1V:2H slopes. A 6-feet-wide inspection trench will be excavated along the levee alignment to find any pervious zones that have not been detected from borings. These trenches will be backfilled with the excavated material or filled with levee fill.

Figure 76 and Table 85 show the levee design reaches that were used for seepage and slope stability analyses. The levee was divided in these reaches that maintain similar site geometry and soil stratigraphy. The subsurface profiles along the creek show an increase of depth from levee to bedrock from upstream to downstream (left to right in Figure 76). The stationing of the right bank and left bank are based on a 2024 alignment.

Figure 76. Levee design reaches.

Table 85. Levee design reaches with stationing.

Reach	Left Bank Stationing	Right Bank Stationing
1	0+00 to 31+50	0+00 to 9+00
2	31+50 to 43+50	9+00 to 21+50
3	43+50 to 52+00	21+50 to 30+50
4	52+00 to 72+00	30+50 to 49+00
5	72+00 to 82+00	49+00 to 57+00

The design team performed slope stability analyses for 6 cross sections within these reaches. These analyses were conducted using GeoStudio SLOPE/W program. Representative levee cross sections within the reaches from Table 85 were used. In most cases, the tallest levee sections were analyzed. The levee height from two of these sections was 9 feet. The design of the levee crest has a width of 10 feet, but in some instances a crest of 14 feet was considered as well. The crest width did not have a negative impact on the results. The City of Merriam had expressed their desire of a 14-foot-wide crest to allow more room for pedestrians and bicyclists. Slope stability analyses were conducted to meet criteria per EM 1110-2-1913 (2000) and EM 1110-2-1902 (2003b). The water level was set at top of levee for the analyses.

The evaluated cases were end of construction with undrained soil strengths (Factor of Safety of 1.3) and steady-state with drained soil strengths (Factor of Safety of 1.4). The end-of-construction condition used undrained soil strengths from unconsolidated undrained (UU) triaxial tests. The drained soil strengths were based on effective stress plots of consolidated undrained (CU) triaxial tests with pore pressure measurements. There were difficulties obtaining soil samples for testing, which is why only 3 UU tests and 4 CU tests were performed. Due to the limited set of tests, assumptions needed to be made in the selection of the parameters and were based on values from literature and experience.

Table 86 shows the material properties used in the initial set of analyses. A total of 19 borings have been conducted in the project area, 2 of them were part of the feasibility phase in 2002 and the other 17 in 2023. The soil profile shows that the subsurface where the levees will be constructed is mainly clayey fill or clayey natural soil down to shallow bedrock with no consistent sand layer. While the soil stratigraphy does not show a continuous pervious stratum, the design team assumed for modeling purposes that there is a zone where seepage could flow through. This zone includes weathered rock, gravelly clay, and the voids and joints of bedrock.

Table 86. Material properties used in slope stability analyses.

Material	Unit Weight (pcf)	Cohesion (pcf)	Phi (degrees)	Hydraulic Conductivity (ft/s)
Embankment	120	0 (drained) 1000 (undrained)	2 (drained) 0 (undrained)	7.5E-06
Blanket	115	0 (drained) 1000 (undrained)	2 (drained) 0 (undrained)	7.5E-06
Pervious Stratum	115	0 (drained) 0 (undrained)	31 (drained) 31 (undrained)	3E-03

Table 87 shows the results of the initial slope stability analyses. Analyses were conducted for end of construction with undrained parameters and all results indicated that they meet the minimum factor of safety of 1.3. The lowest factor of safety was 4.5. However, some of the cases with steady state conditions with drained strengths did not result in minimum factors of safety of 1.4. Some of them were as low as 0.8. To be able to achieve the minimum of 1.4, some modifications to the levee design were incorporated wherever it was needed. These included stability berms, sand drains, or a combination of both as seen in Figure 77. The results of the analyses with the stability remediations are shown in the last column of Table 87.

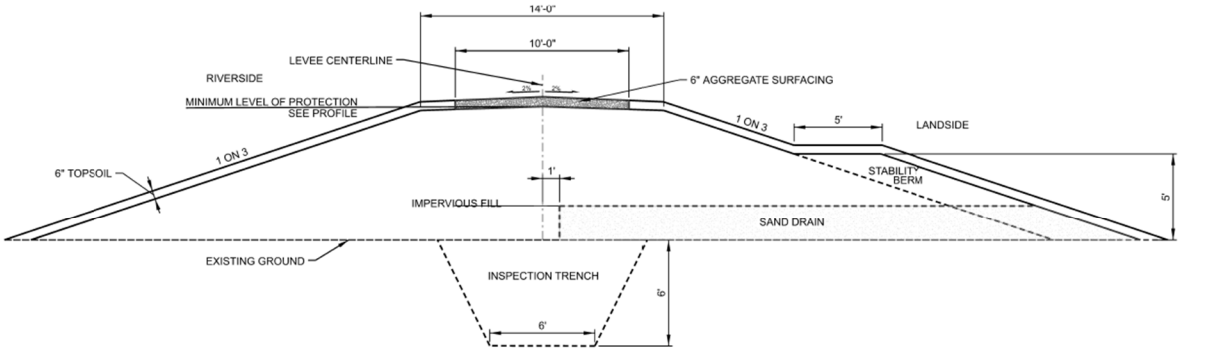

Figure 77. Typical levee section of Reach 2 LB: 40+80 showing sand drain and stability berm.

Table 87. Slope stability factors of safety for end of construction and steady state seepage conditions.

Reach	Levee Height (ft)	End of Construction Factor of Safety (Undrained)	Steady State Factor of Safety (Drained)	Steady State Factor of Safety (Drained) with Stability Remediation
Reach 1 LB: 28+00 Tallest Levee	4.0	10.4	1.4	-
Reach 1 RB: 2+00 Tallest Levee	2.5	20.8	2.1	-
Reach 2 LB: 40+80 Tallest Levee	7.0	4.5	0.8	1.6 w sand drain and 5' tall 5' wide berm or 1.6 w sand drain and 14' crest
Reach 2 RB: 18+20 Tallest Levee	9.0	4.5	0.8	1.4 with sand drain and 5' tall 10' wide berm or 1.4 with sand drain and 14' crest and 5' tall 5' wide berm
Reach 4 RB: 41+20 Tallest Levee	9.0	4.9	1.0	1.4 with sand drain
Reach 5 LB: 77+80 Tallest Levee	5.0	10.3	1.4	-

Although the remediations would increase the factor of safety of steady state, drained conditions to a minimum of 1.4, these added features require a wider footprint and higher costs. The design team proposed using the SQRA to evaluate if steady state could really be achieved for this project due to the flashy nature of the creek. If it is determined that steady state conditions are unlikely or not possible for the levees, this would allow recommending the removal of stability remediations such as the stability berms and sand drains from the levee design. Hydrographs show that water level remains shallow within the channel most of the time and that it rises and falls very quickly during floods. In addition, the fine-grained material of the levee and blanket would not have the capacity of allow sufficient flow through. Therefore, it is possible steady state conditions and drained strengths would not be applicable for the levees in this project. To verify how this assumption has an effect on the design and to inform the risk assessment, slope stability analyses with transient seepage were conducted. Transient seepage analyses are not considered reliable for design, which is why the USACE does not recommend them for initial design mostly due to the difficulty in the ability to measure the parameters for unsaturated soils. Nevertheless, transient seepage can be used in a risk assessment with sensitivity analyses to evaluate the development of pore pressures with time.

Slope stability models with transient seepage were conducted for the levee sections that did not meet the steady state factor of safety of 1.4. The models were run with these levee sections without the stability remediations to verify if they were necessary or not to meet the minimum factor of safety. While some adjustments were made to the hydraulic conductivities, the models used the same soil parameters for the most part. Volumetric water content and compressibility were estimated from consolidation tests and used for the blanket and embankment materials. For the pervious stratum, values from literature were used.

Soil–water characteristic curves (SWCC) were generated within GeoStudio. Table 88 shows the material properties used for transient seepage modeling.

Table 88. Material properties used for transient seepage analyses.

Material	Saturated Water Content	Hydraulic Conductivity (ft/s)		Compressibility (1/psf)			Rationale
		expected	high	low	expected	high	
Embankment	0.4	1.0E-06	-	3.0E-06	1.13E-05	1.96E-05	Assumed identical to blanket
Blanket	0.4	1.0E-06	1.0E-04	3.0E-06	1.13E-05	1.96E-05	Computed from 5 consolidation test results
Pervious Stratum	0.4	3.0E-03	-	-	1.13E-06	1.13E-05	Assumed medium-loose sands

Slope stability analyses with transient seepage and drained strengths combined with sensitivity analyses were performed for Reach 2 LB Sta. 40+80, Reach 2 RB Sta. 18+20 and Reach 4 RB Sta. 41+20. Adjustments were made to the hydraulic conductivity, compressibility, and initial water level in the analyses to verify how sensitive the results were to changes in these parameters. Hydrographs with the expected duration were incorporated in the models to make the analyses time dependent. Figure 78 shows an example of a hydrograph with expected duration used for Reach 2 LB Sta 40+80. All the hydrographs at the locations used for the analyses show that the rise and fall of water level between toe and levee crest takes less than 2.5 hours. The slope stability models were run with the water level at top of levee. The lowest factors of safety obtained from these slope stability models resulted in factors of safety of 1.5. In addition, the hydrographs were extended with durations that were two times and five times longer (2x and 5x) to exaggerate the duration of the water surface elevation above the waterside toe and study the influence of time in the development of pore pressures within the embankment and blanket. The risk assessment team decided to not rely on these extended hydrographs as they seemed to be unrealistic based on the available data and the nature of the watershed. Nevertheless, the cases that were run with a hydrograph that had an extended duration 2x resulted in similar factors of safety to the ones that used the expected duration. A flood duration up to twice as long as expected does not result in a significant increase in the total head at the landside toe for any cases of varying soil parameters.

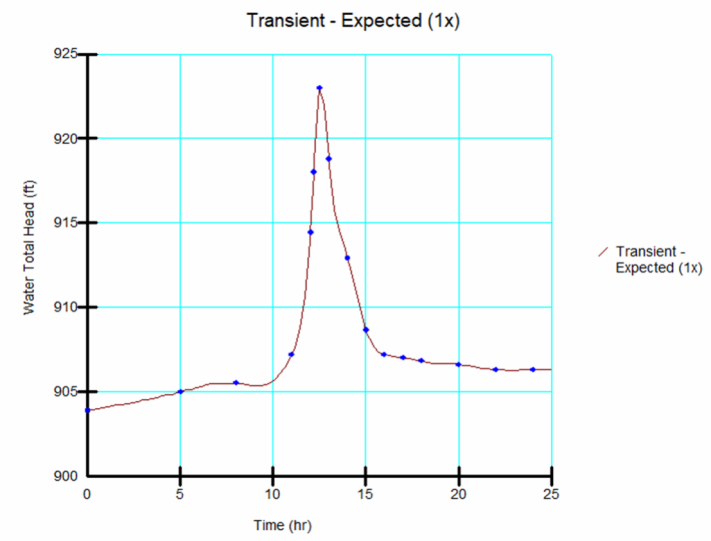

Figure 78. Hydrograph used for transient seepage in Reach 2 LB Sta 40+80

In the transient analyses, in no case did the embankment become saturated. The wetting front progressed no more than ~10% through the width of the embankment, and that was for the 5x the expected hydrograph duration. Figure 79 shows the results of the slope stability analysis at top of levee and it can be noticed from the phreatic surface line that seepage barely penetrates through the embankment. Pore water pressure development in the blanket was more significant than within the embankment. Pore water pressures in the blanket were tracked using nodal points 3 feet and 6 feet below the landside toe of the embankment, since this is the location most relevant to slope stability. The results from all the analyses show that steady state seepage conditions will not be possible in the levee. Rainfall producing the flood loading would also be present at the levee, which could lead to infiltration and affect pore water pressures. However, the lag time between the rainfall and peak flood levels is less than an hour, so it is unlikely that infiltration would be significant in the short duration before peak flooding occurs. Table 89 shows the results of the slope stability analyses with transient seepage.

In addition to evaluating whether or not steady state conditions could be achieved, the design team and SQRA team reassessed the soil strength parameters used in the original steady state analyses. Drained shear strengths were defined using the Mohr's circles obtained from consolidated undrained (CU) triaxial testing and a cohesion intercept of zero; assuming the cohesion intercept is zero is a conservative estimate for soil strengths as adding even a small amount into stability modeling can have a sizeable impact on making slopes calculate as stable. The selected strength plotted on the Mohr's circle envelope is shown in Figure 80. However, this plot was considered too conservative and underrepresented the available strength in the soils, particularly at higher stresses, given the difference between the tested effective stress envelope and the estimated effective stress envelope. In order to more accurately define the soil strength, while still maintaining a cohesion intercept of zero, a curvilinear drained strength function was used (Figure 81). Using this curvilinear drained strength function resulted in factors of safety above the required 1.4 for the steady state condition (Table 90).

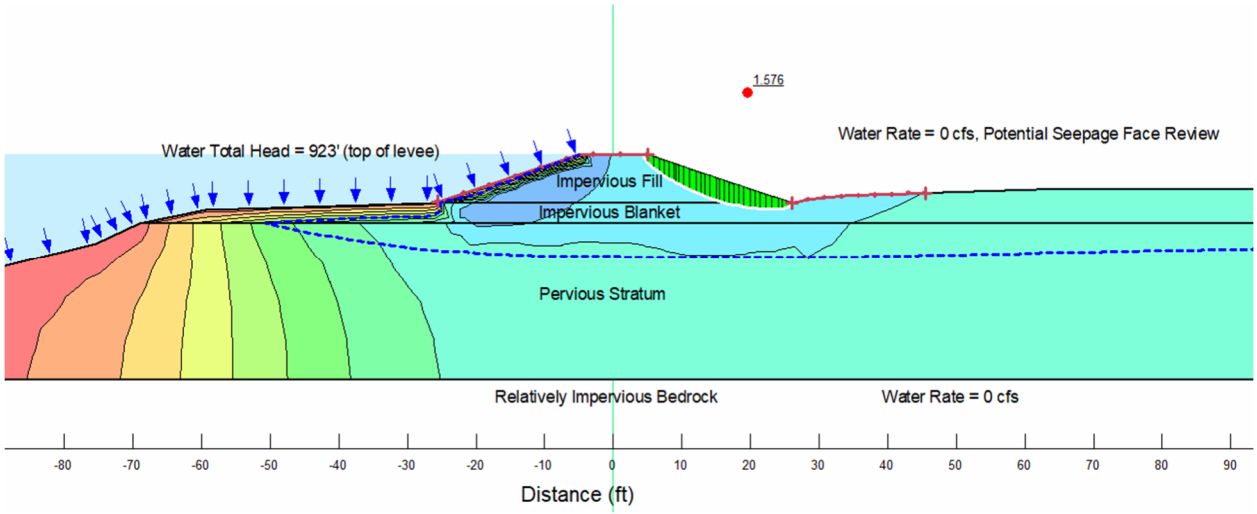

Figure 79. Slope stability analysis at top of levee in Reach 2 LB Sta 40+80

Table 89. Results of slope stability analyses with transient seepage.

Cross section	Case	Hydrograph	Factor of Safety
Reach 2 LB Sta. 40+80	impervious m_v - high initial condition = 904	Expected	1.57
		Extended (2x)	1.57

7.4.3. Performance

The levee is in its design phase. Therefore, there is no information about its performance.

7.4.4. Intervention

Intervention is unlikely to occur during a short duration, extreme flood event. The Turkey Creek watershed does not have flood forecasting capabilities such as those available through the National Weather Service. The upstream drainage area of Turkey Creek is approximately 12 square miles and heavily urbanized. Storm events of sufficient magnitude result in very flashy floods that leave little time to prepare or respond to.

7.4.5. Likelihood of Failure

Table 91 summarizes the likelihood factors that make the PFM more likely or less likely to lead to failure.

Table 91.
Likelihood factors for PFM 07.

More Likely (Adverse) Factors	Less Likely (Favorable) Factors
• Foundation soils are relatively weak, they are not compacted/controlled fill.	• **Duration of flood loading is expected to be less than 24 hours with peak elevations lasting less than 3 hours.**
• Intervention is not possible with the short duration of flood loading and associated intense storm event.	• Majority of borings show a consistent impervious zone between base of levee and bedrock (seepage modeling assumes some amount of pervious transmission for modeling purposes).
• There is no higher strength zone within the embankment (uniform fill) that would arrest continuation of multiple slope instabilities.	• **A flood duration up to twice as long as expected does not result in a significant increase in the total head at the landside toe for any cases of varying soil parameters.**

More Likely (Adverse) Factors	Less Likely (Favorable) Factors
•	• **Flood loading is insufficient in duration to result in pore water pressure development within the fine-grained embankment beneath the crest and landside slope.**
	• Successive failures may occur as flood level is dropping which may result in crest not lowering below the current water level in quick enough of a duration.
	• Small, unregulated watershed upstream of the levee. There are no cases that could lead to extended durations of moderate to high flows.

NOTE: Key factors are shown in **bold**.

The annual probability of failure was estimated between **3E-7** and **3E-6** with and without intervention.

7.4.5.1. Rationale

Flood loading: 1/130 AEP

The initiating mechanism of slope stability failure could be a combination of an increase of load on the waterside slope with a decrease in strength of the levee due to pore pressures. While a flood could load the levee, its short duration and the low hydraulic conductivity of the embankment fill make it unlikely for the development of pore water pressures that could weaken the levee.

When the waterside slope is loaded, the probability of initiating a slope stability failure is very unlikely.

An initial slope stability failure could lower the crest and there are two potential scenarios: the instability is so severe that it lowers the crest and leads to uncontrolled release of water into the protected area (breach) or the crest is lowered but not enough for an imminent breach. The team determined that there is an equal probability that the initial slope stability failure would be severe enough to cause breach or not (neutral).

It is virtually certain that there are no higher shear strength zones in the levee design to arrest the continuation of slope instability, based on the information provided to the team. There are no plans to add a zone with a different material within the levee.

There will be no activities during a flood to intervene and prevent a slope stability failure.

Since it is certain that intervention will be unsuccessful, at this point the retrogressive instability would advance through the crest leading to uncontrolled release of water. A full breach was estimated to be unlikely due to short duration of peak loading and seepage through embankment not reaching steady state, as it was made evident from the slope stability analyses with transient seepage.

7.4.5.2. Uncertainty

While it is known that floods will be of short duration, it is uncertain if consecutive floods could saturate the levee. Also, there are some uncertainties related to the soil properties. Assumptions had to be made for modeling related to shear strength, hydraulic conductivity, compressibility, etc. due to limited set of tests. In addition, the levee has not been constructed, and a burrow source location has not been identified yet.

7.4.6. Incremental Life Loss

The average incremental life loss was estimated between 0.3 and 3.

7.4.6.1. Rationale

It was estimate that the average life loss is 1 if a breach of the levee occurs in this scenario based on the consequences models.

7.4.6.2. Uncertainty

Discuss

7.4.7. Incremental Economic Cost

The average incremental economic cost was estimated between $3M and $30M.

7.4.7.1. Rationale

Synthesize

7.4.7.2. Uncertainty

Discuss.

7.5. PFM 13: Internal migration into sanitary sewer

7.5.1. Description

Turkey Creek flows through the City of Merriam, crossing many public and private utilities. One of the most prominent of these utilities is a 42” sanitary sewer main. The sanitary sewer crosses the creek bottom 3 times, the levee/floodwalls in 6 locations, and parallels the levee within the influence zone between stations 11+84 to 65+83 (Turkey Creek centerline stationing). The sanitary sewer has manholes present on the landside and riverside of the levee.

Failure of the sanitary sewer and infiltration through riverside manholes or lines located within the riverside area can move a significant amount of soil in a short time. The soil removal erodes away at the levee/floodwall footprint and causes instability. This results in a failure of the levee embankment/floodwall with associated loss of life and economic consequences. An event tree of this

failure description is shown in

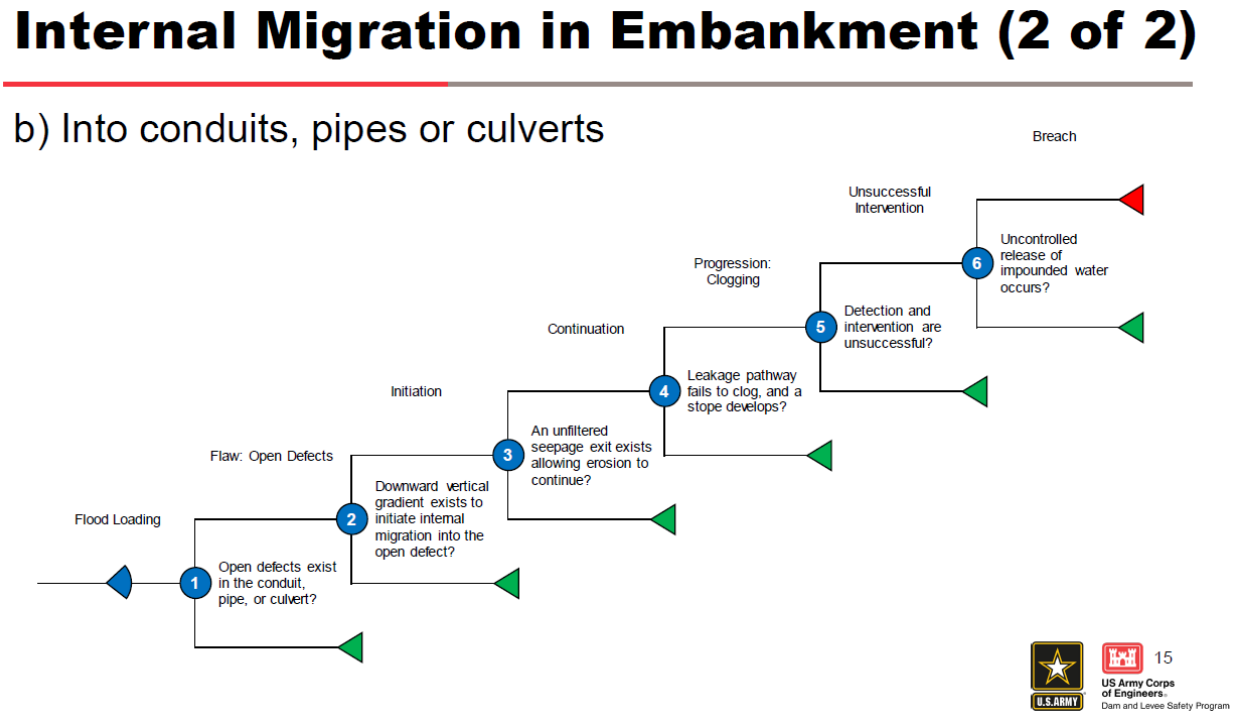

Figure 82.

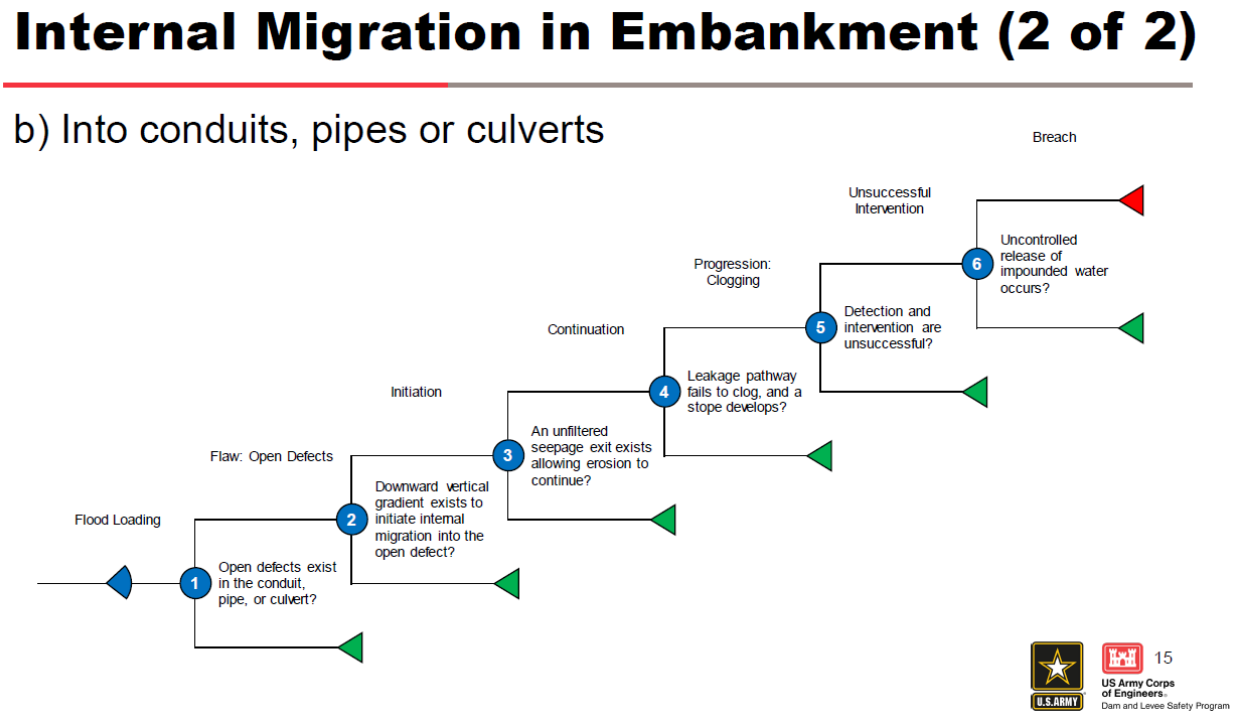

Figure 82. Event tree for PFM 13.

7.5.2. Background

In total, there are approximately 110 utilities that may impact the construction and operation of the Upper Turkey Creek levee system. The utilities include underground electric, communication/fiber, natural gas, water supply, storm sewer, and sanitary sewer. Some of the utilities have a simple crossing within the levee footprint and others run parallel in and out of the levee influence zone. The most notable of the utilities that have a PFM is a 42" sanitary sewer main.

The sanitary sewer system in this area was constructed in the 1950s and video inspected by the utility owner every 10 years with the last inspection occurring in 2014. Results from the video inspection deemed the pipe to be in good condition and not recommended for replacement.

The 42" sanitary sewer crosses creek bottom in 3 locations, the levee in 6 locations, and runs parallel to the levee for approximately 5,400 feet. The sanitary sewer is laid on or within bedrock for most of the run, as seen in the as-built in Figure 83. A crossing of the design levee and the sanitary sewer can be found below in Figure 84 with the profile in Figure 85. The floodside manhole is located 175' from the toe of the design levee. The top of design levee is approximately 927' and the top of the 42" sanitary sewer is approximately 915', leaving a potential of 12' of water loading during the maximum design flood. The natural ground surface in this area is approximately 925.5' so the construction of the levee in this area would only add approximately 1.5' of water loading to the existing pipe.

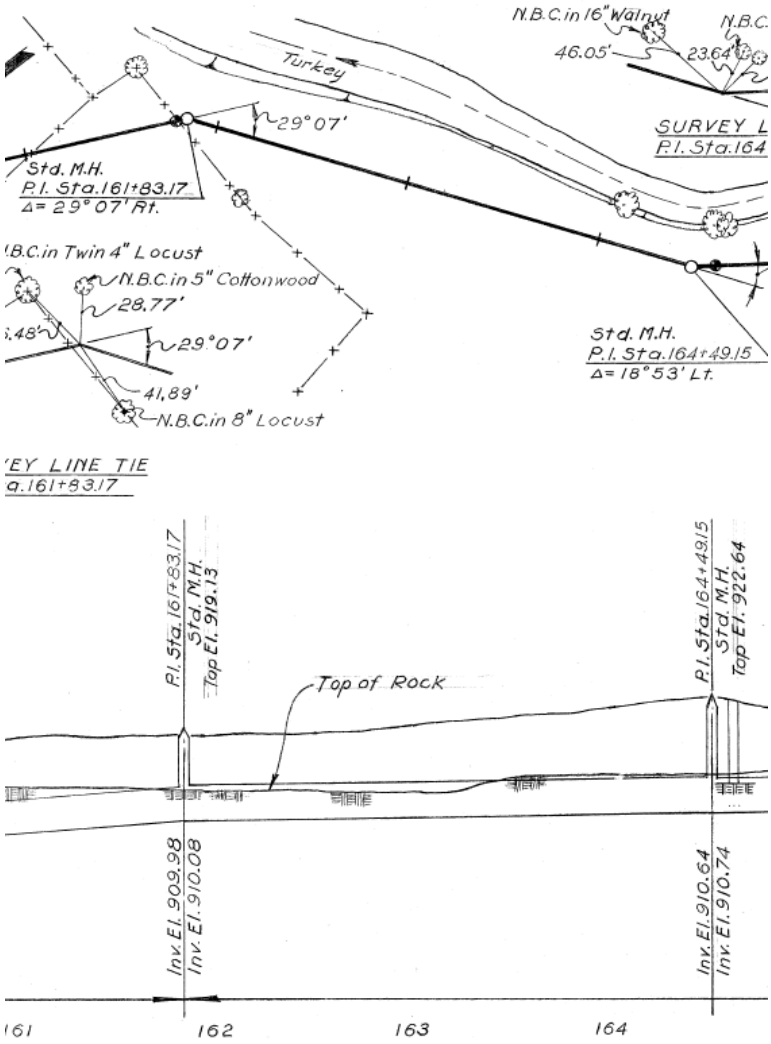

Figure 83. Sanitary Sewer As-built (1959).

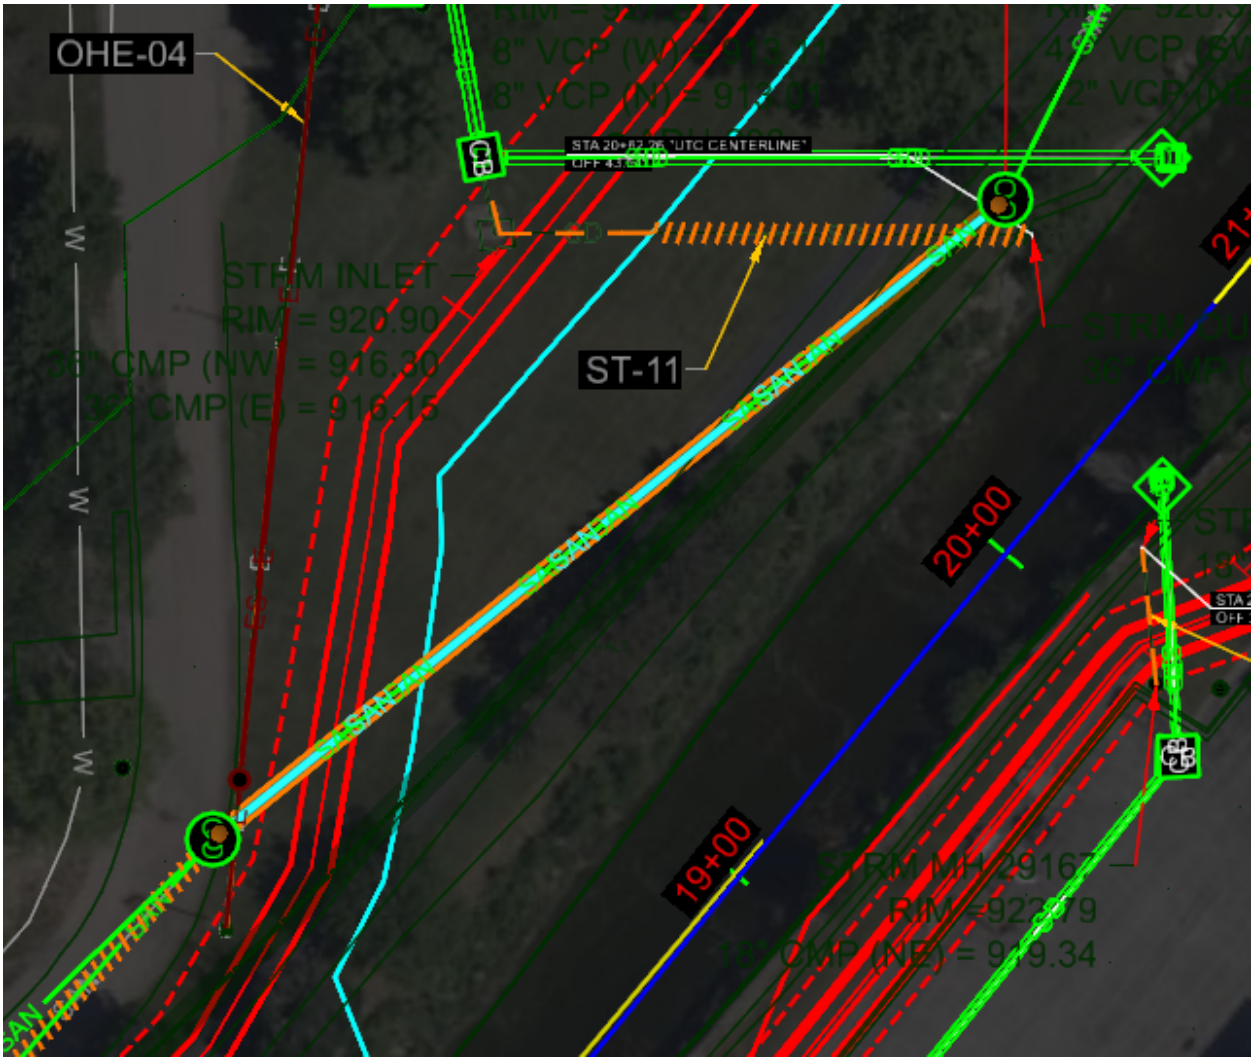

Figure 84. Example location of 42” Sanitary Sewer crossing.

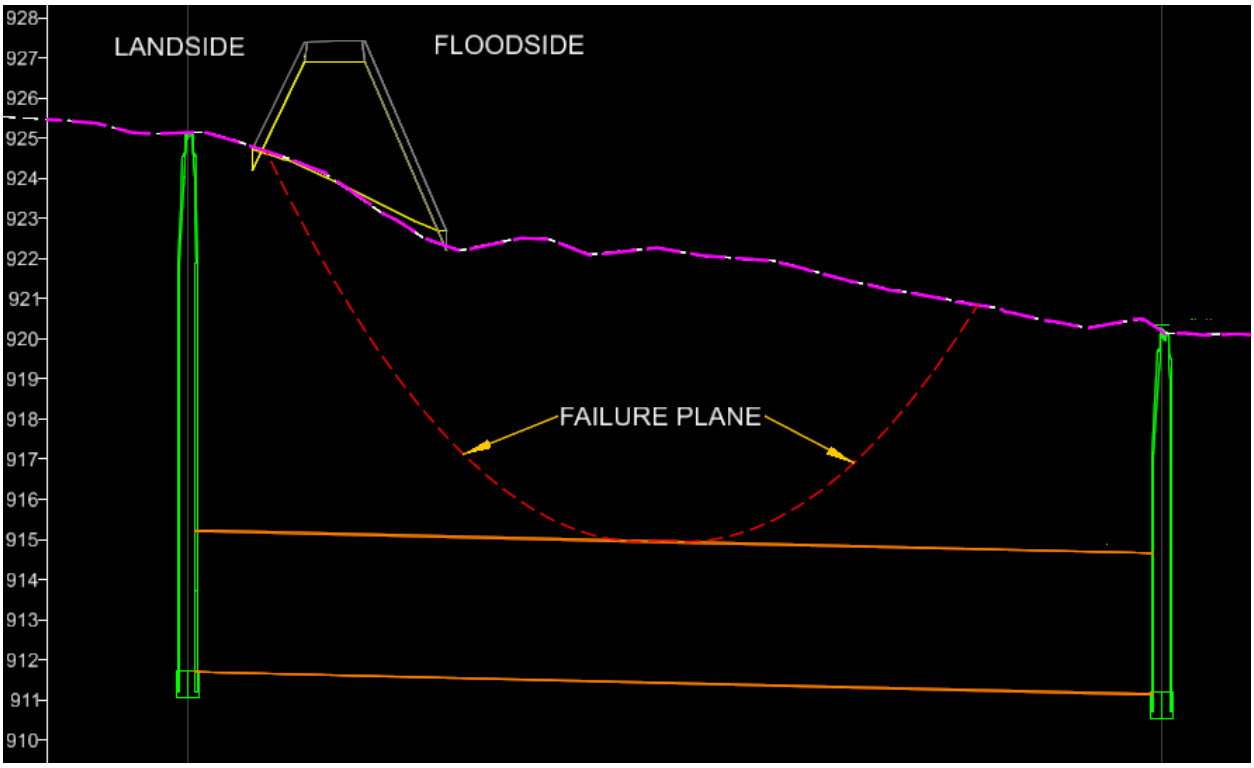

Figure 85. Failure Mode of PFM 13.

7.5.3. Performance

The levee system is in the design phase, and thusly, has no performance history. The sanitary sewers have no known history of internal migration.

7.5.4. Intervention

The first course of action is to relocate all utilities directly impacted by the construction of the levee/floodwalls. This includes shallow utilities such as underground electric, communication/fiber, natural gas, water lines, storm sewer, and sanitary sewer service lines. In some instances, these utilities will be replaced during construction instead of relocated outside of the levee influence zone. Storm sewer will be replaced with RCP and in many cases, located deeper to avoid the floodwall. All other utilities besides sanitary sewer will be relocated up and over the levee/floodwall.

Sanitary sewer lines not directly impacted by construction of the levee/floodwall will be inspected on condition of the pipe and manholes. In some instances, the sanitary sewer may need to be replaced in-kind or internally lined to mitigate the risk of failure. If the sanitary sewer is deemed to be in good condition, it may be left in-place under the levee/floodwall construction. In addition, all manholes within the floodside of the levee will have the rim raised above the 1/25 AEP. A summary of utility decisions can be found below in Table 92.

Table 92: Utility Relocation/Abandonment/Replacement Decision Matrix.

Type	Concern	Associated PFMs	Recommended measure

Existing manhole on floodside	Floodside not preferable because of access, floodside could be problem if manhole allows infiltration of material, overtopping into manhole can cause sewer backups	Internal migration into, overtopping into sewer (backflow)	Inspect all floodside manholes, line to ensure no internal migration where needed (cracks, holes, etc.), raise to above 1/25 AEP flood level, Some cases may need full manhole replacement (e.g., brick). Consider short duration of peak water levels.
Existing manhole on L/W alignment	Not desirable, but may be similar to a gatewell structure in a levee, Difficult to compact, could allow internal migration	Internal migration into	Relocate
Existing manhole within 15-feet of toe	Could allow internal migration	Internal migration into	Inspect, line to ensure no internal migration where needed
Channel-crossing pipe	Internal migration into pipe could occur on floodside of L/W, although DIP has 100-year design life	Internal migration into	Televise inspect all crossing pipes, verify age and material, line if any defects are found. There are 6 sanitary pipes crossing the channel.
Through-pipe under levee	Internal migration could occur due to additional weight of levee of levee	Collapse, internal migration into	Inspect per EM 1110-2-2902 Section 6.4.5, Similar to the channel crossing pipe but with additional soil load
Through-pipe under floodwall	Internal migration could occur due to additional weight of floodwall	Collapse, internal migration into	Inspect per EM 1110-2-2902 Section 6.4.5. Similar to the channel crossing pipe but with additional soil load and/or sheet pile driving
Parallel pipe under levee	Internal migration could occur due to additional weight of levee, RCP pipe could crack (100-year design life)	Internal migration into, collapse	Controlled by manhole relocation, Inspect per EM 1110-2-2902 Section 6.4.6. Line if in poor condition. Try to avoid this alignment if possible.

Parallel pipe under floodwall	Internal migration could occur due to additional weight of floodwall, RCP pipe could crack (100-year design life)	Internal migration into, collapse	Inspect per EM 1110-2-2902 Section 6.4.6. Line if in poor condition. Try to avoid this alignment if possible
Parallel pipe within 15-feet of levee toe	Internal migration into	Internal migration into	Inspect per EM 1110-2-2902 Section 6.4.6. Line if in poor condition.
Parallel pipe within 15-feet of floodwall toe	Internal migration into	Internal migration into	Inspect per EM 1110-2-2902 Section 6.4.6. Line if in poor condition.
Parallel pipes outside 15 feet	No concern	No PFM	No action

*Pressurized pipes that are parallel (water, gas, etc.) need to be relocated outside the levee footprint (PFM 35)

7.5.5. Likelihood of Failure

Table 93 summarizes the likelihood factors that make the PFM more likely or less likely to lead to failure.

Table 93.
Likelihood factors for PFM 13.

More Likely (Adverse) Factors	Less Likely (Favorable) Factors
• Pipes installed are more than 50 years old, so may have some deterioration leading to flaws.	• Short duration of flood loading (< 24 hours, <3 hour peak loading) may not allow for progression to failure
• Pipes are not frequently expected and have not been inspected since 2014. Pipes are third-party pipes not maintained by the sponsor.	• A flaw at the channel crossing pipe would be further from the alignment, so not as likely to directly collapse the levee/wall
• Intervention during a single event is very unlikely given the short duration of the storm.	• Pipe material ranges from ductile iron pipe (DIP). Clay, concrete, and PVC with design life ranging from 75-150 years, and may still be in good condition (~50 year old pipes).
• A 1/10 AEP water surface would have approximately 13.5 feet of head over the pipe. A 1/100 AEP water surface would have 17 feet of head. The vertical gradient may be sufficient to move material.	• Last inspection (2014) showed pipes in good condition and pipes will be televised prior to adopting them into the project. Any major defects identified will be mitigated (e.g., slip line).
• Exit is unfiltered as sanitary line can continue to move material away from the site with gravity.	• Could be possible to identify initiation and progression of this type of PFM between successive floods. Requires two ore more events greater than 1/5 AEP (out of bank) to 1/10 AEP (toe elevation).
• Pipes are up to 42” diameter, so may not clog with material	• Clay material above the pipe is less likely to migrate than other materials.

NOTE: Key factors that drove the likelihood of failure are shown in **bold**.

The annual probability of failure was estimated between 1E-05 and 1E-04 (with and without intervention).

7.5.5.1. Rationale

Flaw – assumes that the pipe has been inspected and shows no obvious defects. Over the levee design life, these pipes may be reaching the end of their design life and may not be inspected as frequently as required (i.e., every five years). It is unlikely there is a flaw, but possible.

Initiation – short duration of flood may not lead to the flaw experiencing the full hydraulic head due to the clay material, but still have some amount of head that make initiation neutral.

Continuation – the pipe can carry material along the pipe with gravity with no real limiting point that would stop material from moving, so estimated to be likely.

Progression: clogging – The flaw in the pipe, the size of the pipe, and the type of material may not efficiently move into the flaw at a fast enough rate given the flood duration, so estimated to be neutral.

Unsuccessful intervention – repairs between floods are possible but intervention is not possible during a single event. The duration and peak duration are very short and would be occurring along with intense rainfall.

Breach – flood peak may have receded below the toe by the time of failure.

Loading	1/130
Flaw	0.1
Initiation	0.5
Continuation	0.9
Progression	0.5
Unsuccessful Intervention	0.999
Breach	0.1
Total APF	2E-05

7.5.5.2. Uncertainty

Discuss any sources of significant uncertainty related to the likelihood of failure, which includes both the hazard (loading) and performance (conditional probability of failure). Reference Chapters 4 and 5 for sources of significant uncertainty with the hydrologic and seismic hazards, respectively.

7.5.6. Incremental Life Loss

The average incremental life loss was estimated between 0.3 and 3.

7.5.6.1. Rationale

Synthesize the consequence estimates, mapping products, hydraulic and consequence modeling assumptions to build the case for the average incremental life loss. These include breach dimensions and timing, depths, incremental flows and depths at consequences areas, and arrival times. Discuss their appropriateness for the identified PFMs and site-specific conditions which make the life loss estimate better or worse than the modeled assumptions and estimated life loss.

If the average incremental life loss is very similar or the same as a previously evaluated PFM, do not repeat the information. Reference the previously evaluated PFM (e.g., the breach characteristics and thus the rationale are similar to PFM ##) or discuss what is different for the evaluated PFM.

7.5.6.2. Uncertainty

Discuss any sources of significant uncertainty related to the average incremental life loss which includes the hydraulic modeling (e.g., breach parameters and flood characteristics) and consequence modeling (e.g., emergency preparedness, warning and evacuation, etc.).

7.5.7. Incremental Economic Cost

The average incremental economic cost was estimated between _____ and _____.

7.5.7.1. Rationale

Synthesize the consequence estimates, mapping products, hydraulic and consequence modeling assumptions to build the case for the average incremental economic cost. Discuss their appropriateness for the identified PFMs and site-specific conditions which make the economic cost estimate better or worse than the modeled assumptions and estimated economic cost. Include repair or replacement costs if appropriate and the resources used to estimate them. Include any benefits foregone with the direct property damages and describe the period during which the project is considered out of service for the lost benefits estimate.

If the average incremental economic cost is very similar or the same as a previously evaluated PFM, do not repeat the information. Reference the previously evaluated PFM (e.g., the breach characteristics and thus the rationale are similar to PFM ##) or discuss what is different for the evaluated PFM.

Provide the loss of service economic cost separately because DSAC only considers risks associated with breach and uncontrolled release.

7.5.7.2. Uncertainty

Discuss any sources of significant uncertainty related to the average incremental economic cost which includes the hydraulic modeling (breach parameters and flood characteristics) and consequence modeling (limitations of structure inventory, repair costs, etc.).

Appendix A: Excluded Potential Failure Modes

The following sections summarize the potential failure modes that were excluded from further consideration because they were deemed non-credible or credible but non-risk drivers.

A.1. PFM 1: Overtopping breach of the levee

The team determined that this PFM is a risk driver, see Chapter 7.

A.2. PFM 2: Overtopping breach of the floodwall (I-wall)

PFM 2 requires erosion on the landside toe of the floodwall due to overtopping for sufficient duration. Plunging flow from overtopping would scour erodible material on the landside toe causing the I-wall to become unstable and collapse suddenly, allowing uncontrolled flow into the leveed area.

This failure mode was determined to be a non-risk driver based on design recommendations. Currently most of the locations being considered for I-walls (less than 7-feet tall) have asphalt or concrete paving on the landside toe, which can better withstand short durations of overtopping plunging. Whether that be parking lots, sidewalks, or roads. Because I-walls are only going to be used in locations where the floodwall would need to less than 7-feet tall, plunging forces are not anticipated to be significant. Additionally, the duration of overtopping flows is expected to be less than 2 hours, as shown in Section 4.4.5, which would limit the possibility of extended scour progression. Tailwater is also expected to develop to at least 1.5-feet through most of the levee for a 2-foot overtopping scenario which would further inhibit toe scour. Figure 86 provides an example of the tailwater depth during peak overtopping at a 6.5-foot-tall section of floodwall.

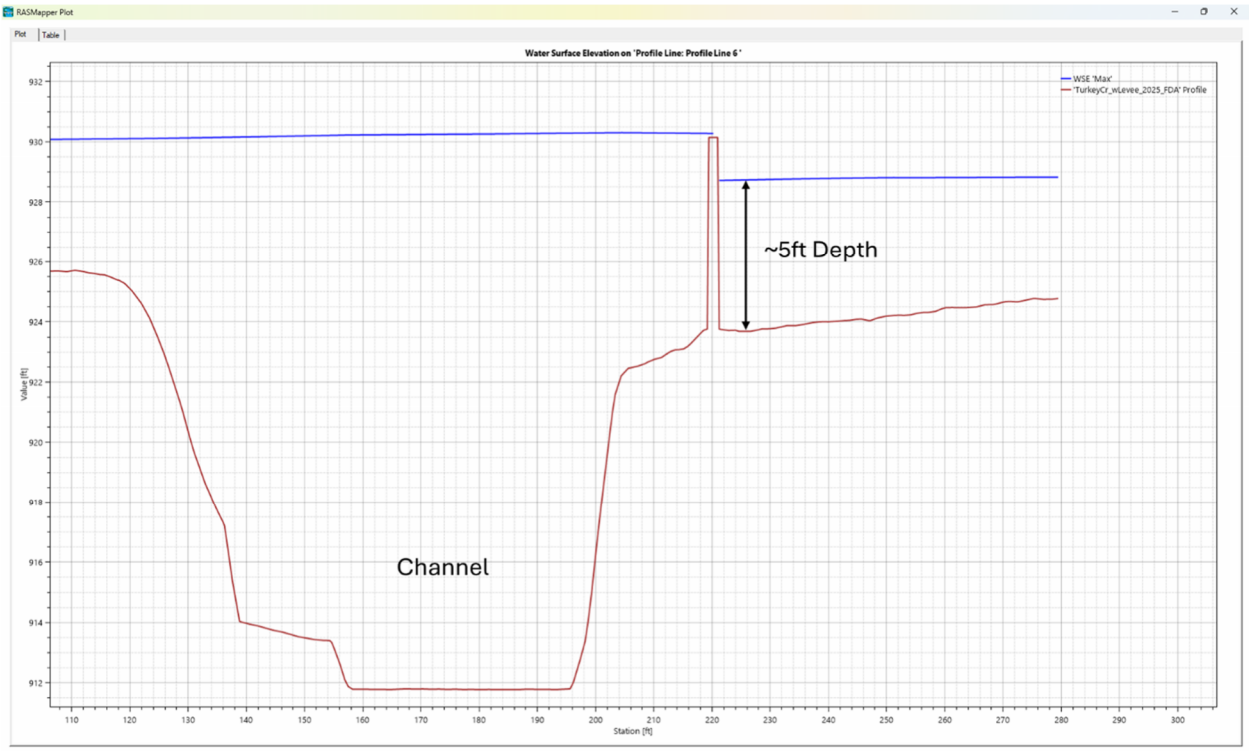

Figure 86. Tailwater development at floodwall with 2-foot overtopping scenario.

Locations where grass is present on the landside toe and I-walls are being used instead of T-walls, it is recommended that riprap be used for armoring. With this information in mind, risk of an overtopping breach for I-walls is expected to be no greater than overtopping breach of the levee (PFM1).

A.3. PFM 3: Concentrated leak erosion (CLE) through the embankment between construction lifts

This potential failure mode considers the potential for CLE to occur through a continuous flaw in the embankment between construction lifts. For the flaw in this potential failure mode to exist and allow CLE to initiate and progress, it is dependent on a number of factors, including poor compaction of the embankment, inadequate embankment material controls, and extended duration for a high loading event that maintains a high differential head.

Specifications have not yet been drafted for this project. Specification 35 41 00 Levee Construction will be the primary specification for construction of the earthen embankment. This specification contains adequate detail for the requirements of materials, placement, compaction, moisture control, scarification, and more pertaining to the construction of the levee. These requirements are expected to eliminate the concern for a continuous flaw through the embankment that would be susceptible to CLE initiation and progression.

The levee loading duration is expected to be less than 24 hours in total for a top of levee loading event. This is not considered a long enough time to allow for CLE to progress in any significant manner, let alone to failure, regardless of if CLE is even able to initiate due to poor construction practices. For these reasons, this potential failure mode was excluded.

A.4. PFM 4: CLE along differential settlement

This potential failure mode considers the potential for CLE to occur through a continuous flaw in the embankment that is created through differential settlement of the embankment. The development of a continuous flaw in this potential failure mode is dependent on several possible factors, including a relatively sudden change in earthen embankment fill height, inconsistent subsurface conditions (localized low stress zones, karstic bedrock features, sudden undulations in bedrock), and/or poor construction practices. For this failure mode to initiate and progress to failure, an extended loading duration near the top of the levee is required to maintain a high differential head.

Based on the 2023 site investigation bore logs and a desktop survey of available historical data, bedrock appears to dip from upstream to downstream in a relatively consistent manner and is not expected to contain sudden undulations. Additionally, the bedrock geology is not known for having karstic or other features that could accept or pass along any meaningful quantity of foundation material that would result in unexpected settlement.

Construction practices are expected to be adequately defined in Specification 35 41 00, which has not yet been drafted, but will be the primary specification for construction of the earthen embankment. This specification contains adequate detail for the requirements of materials, placement, compaction, moisture control, scarification, and more pertaining to the construction of the levee.

A settlement analysis has not yet been conducted but will be completed as part of the design requirements for this project. Any concerns that arise from this analysis about the compressibility of the fill materials and native clays will be addressed during design. To further ensure satisfactory conditions in embankment's foundation, an inspection trench will be dug beneath all earthen levee segments during construction and evaluated for any localized anomalies.

The levee loading duration is expected to be less than 24 hours in total for a top of levee loading event. This is not considered a long enough time to allow for CLE to progress in any significant manner, let alone to failure, regardless of if CLE is even able to initiate due to poor construction practices. For all of these reasons, this potential failure mode was excluded.

A.5. PFM 5: CLE along levee/wall/bridge interfaces

This potential failure mode considers the potential for CLE to occur along the interface of the earthen embankment and structure (floodwall, bridge abutment). Factors that may influence the existence of a continuous flaw at such an interface include poor construction practices and/or differential settlement. For this failure mode to initiate and progress to failure, an extended loading duration near the top of the levee is required to maintain a high differential head.

As stated in PFM 4 and 5, construction practices are expected to be adequately defined in Specification 35 41 00, which has not yet been drafted. In addition to requirements for construction of the earthen embankment, this specification includes additional controls for placement and compaction of embankment materials adjacent to structures to ensure conditions conducive to CLE are not present.

Also as stated in PFM 4, a settlement analysis has not yet been conducted but will be completed as part of the design requirements for this project. Any concerns that arise from this analysis about the compressibility of the fill materials and native clays will be addressed during design. The floodwall is being designed as soil-founded, not pile-founded, and is expected to experience at least a share of the settlement experienced by the earthen embankment.

The levee loading duration is expected to be less than 24 hours in total for a top of levee loading event. This is not considered a long enough time to allow for CLE to progress in any significant manner, let alone to failure, regardless of if CLE is even able to initiate due to poor construction practices. For all of these reasons, this potential failure mode was excluded.

A.6. PFM 6: Flap gate stuck open resulting in backflow into leveed area

PFM 6 occurs if debris were to pin open a flap gate during high channel stages and allow uncontrolled backflow into the leveed interior. Channel water surface elevations higher than the landside drainage structure inlet inverts would produce hydraulic head necessary to backflow into the interior area. Flow could back up through curb inlets, the detention pond drop inlet, or daylighted conduits depending on which flap gate gets pinned open.

This failure mode was determined to be a non-risk driver for a number of reasons. Most of the drainage structures are outlets to underground stormwater systems, and thusly, limits the size of any debris that could pin open a flap gate from the inside as it would likely need to pass through a curb inlet or similar structure. Additionally, the pipes have slopes ranging from 1% to 5% slopes and are likely to be self-cleaning which reduces the likelihood of sediment buildup that could prevent flap gate closure. Large sources of debris from the river, such as logs or branches are unlikely to prevent closure of the flap gates because the river would still need to be at a low/moderate stage for flap gates to be partially open and draining interior flow. Which would not have the velocities and energy to sweep debris downstream. During higher stages that do have the capability to sweep trees downstream, the flap gates would already be well submerged and pinned closed due to the water pressure.

It is recommended that the sponsor inspect the flap gates visually multiple times a year during routine inspections and/or after large storms or flood events which exceed the monitoring stage of 14-feet at the Turkey Creek at Johnson Drive StormWatch gage (TU04). These visual inspections should be conducted to ensure the flap gates are free of debris and functioning properly.

It is recommended to proceed with only one passive closure for each drainage structure, including outfalls greater than 36-inches in diameter. Active closures are not viable alternatives given the flashy nature of the system and the lack of flood forecasting capabilities for the watershed. There also runs a risk of closing a gate well and impounding water on the interior longer than it would have otherwise remained under full passive conditions. The risk to life safety from backflow through an open pipe is zero, and the economic damages related to backflow are minimal as backflow would only lead to small incremental differences in the interior ponding depths in isolated areas. Two examples are shown below. The first is drainage structure ST-15a flap gate on the left bank being stuck fully open for the duration of the top of levee loading scenario. As shown in Figure 87 depths of less than 2 feet make up the majority of inundation on the interior due to backflow, with only 2 structures seeing minor water. The second is the ST-20a flap gate being fully open which allows backflow into downtown Merriam. Backflow into the interior is mostly contained to the streets or parking lots, but some buildings do see inundation of 2 feet or less. The only locations where depths exceed 2 feet are ditches or along the streets as seen in Figure 88.

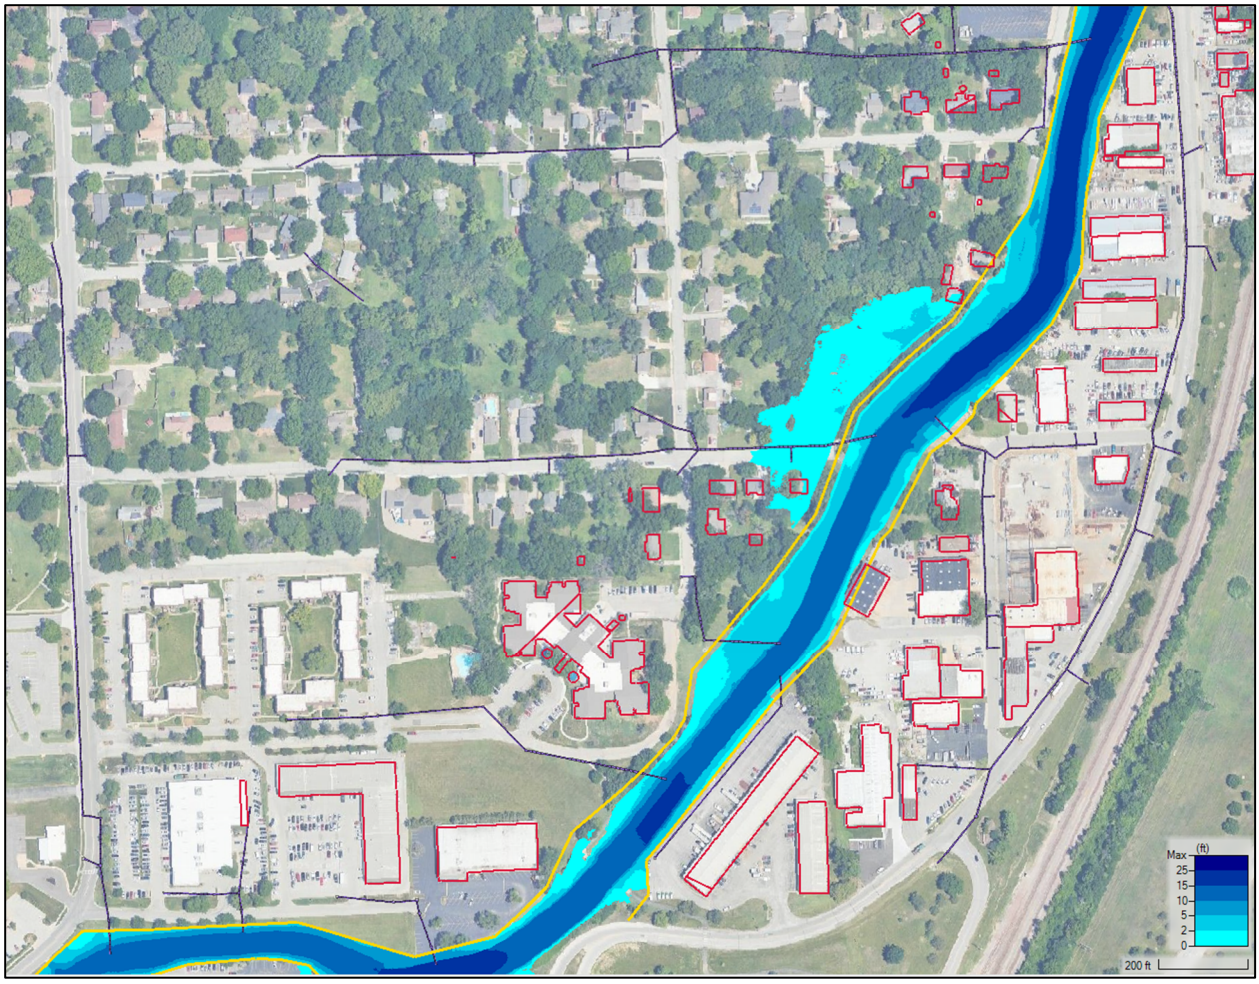

Figure 87. Interior flooding with drainage structure ST-15a flap gate stuck fully open.

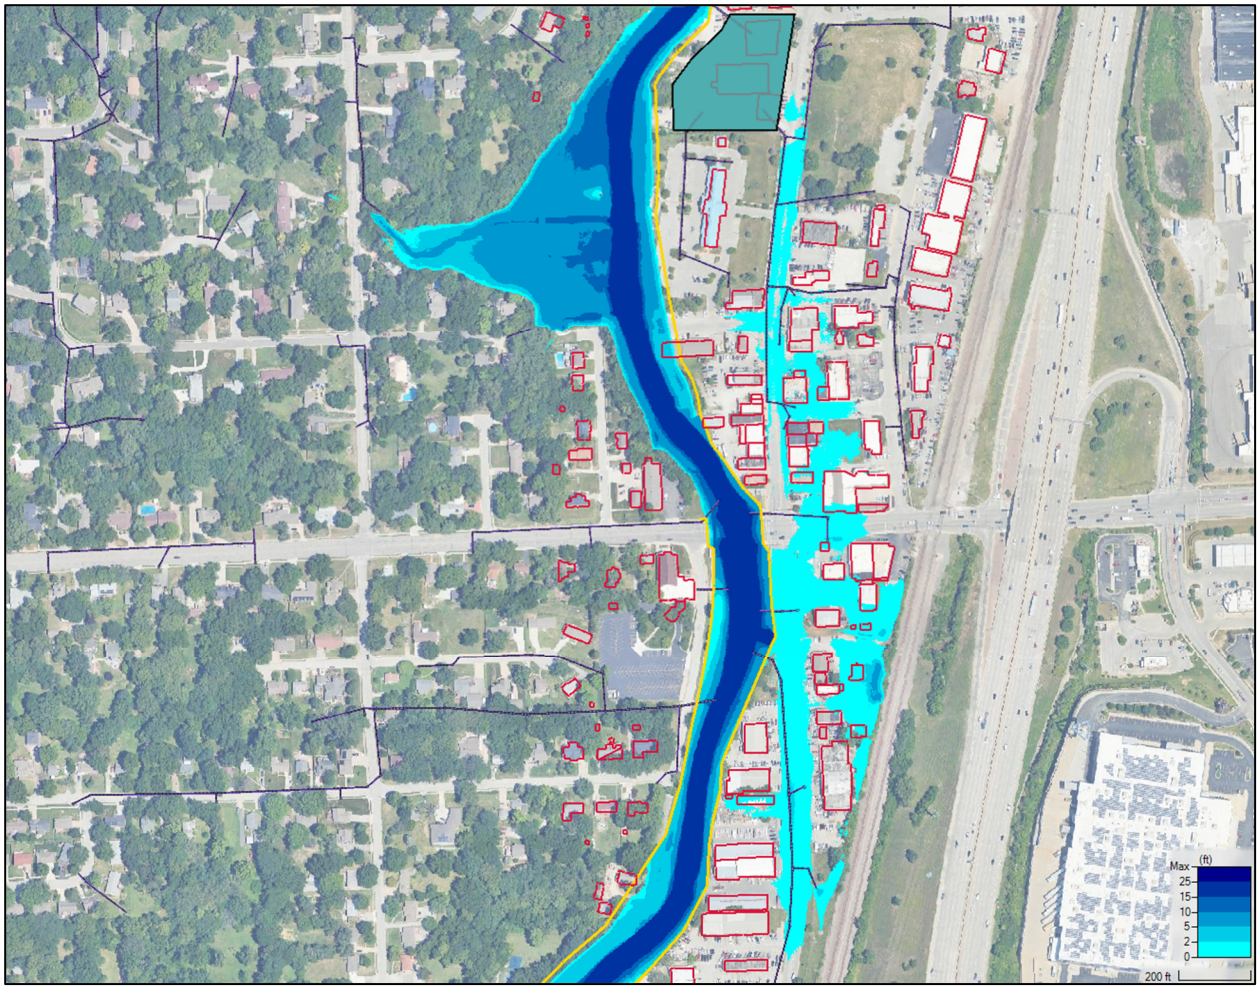

Figure 88. Interior flooding with drainage structure ST-20a flap gate stuck fully open.

A.7. PFM 8: Global instability of the I-wall

This potential failure mode is dependent on the instability of the I-wall. This PFM does not include effects of the destabilization of the limestone wall which is covered in PFM 20.

Requirements for global stability of floodwalls are defined in EM 1110-2-2502 and will be adhered to for the floodwall design. Stability analyses with relevant parameters for end of construction, steady state, and rapid drawdown will be finalized for floodwall following the 35% design milestone. For this reason, this potential failure mode was excluded.

A.8. PFM 9: Global instability of the T-wall

This potential failure mode is dependent on the instability of the T-wall. This PFM does not include effects of the destabilization of the limestone wall which is covered in PFM 21.

Requirements for global stability of floodwalls are defined in EM 1110-2-2502 and will be adhered to for the floodwall design. Stability analyses with relevant parameters for end of construction, steady state, and rapid drawdown will be finalized for floodwall following the 35% design milestone. While more

expensive than I-wall, there does not appear to be physical limitations that would keep T-wall from meeting the design requirements of EM 1110-2-2502. For these reasons, this potential failure mode was excluded.

A.9. PFM 10: Local instability of the I-wall

This potential failure mode is regarding the potential of breaching due to sliding, exceeding the bearing capacity or overturning of the I-wall. The three failures are individual PFMs and may or may not happen at the same time. For sliding, the wall may fail due to excessive horizontal deformations at the very bottom of the sheet pile due to lateral earth pressure and/or hydrostatic pressure, especially during a flood. For bearing capacity, the wall may fail when the pressures that can be permitted against the foundation soils exceed the allowable bearing capacity. The bearing capacity will depend on the loading conditions, compressibility of the soil and geometric considerations. Lastly, overturning of the wall may happen. However, the wall will always fail first due to sliding, exceeding bearing capacity or structural damage before the structure overturns.

The I-walls will be founded on mainly clayey fill or clayey natural soil down to shallow bedrock with no consistent sand layer. Assessment of these potential failure modes must follow the equations and criteria presented in the Engineer Manual 1110-2-2100 Stability Analysis of Concrete Structures (USACE, 2005) and Engineer Manual 1110-2-2502 Floodwalls and Other Hydraulic Retaining Walls (USACE, 2022). The team determined that this PFM is not a risk driver if the follows the appropriate design criteria.

A.10. PFM 11: Local instability of the T-wall

This potential failure mode is regarding the potential of breaching due to sliding, exceeding the bearing capacity or overturning of the T-wall. These three failures are individual PFMs and may or may not happen at the same time. For sliding, the wall may fail due to excessive horizontal deformations. The potential for a sliding failure can be assessed by comparing the resisting shear forces against the acting applied shear forces on the wall. Friction of the base and sides of the T-wall provide resistance against sliding. For bearing capacity, the wall may fail when the pressures that can be permitted against the foundation soils exceed the allowable bearing capacity. The bearing capacity will depend on the loading conditions, compressibility of the soil and geometric considerations. Lastly, overturning of the wall may happen. However, the wall will always fail first due to sliding, exceeding bearing capacity or structural damage before the structure overturns.

T-walls will be used in locations where there is no sufficient space for levees. I-walls may also be considered if design deviation is approved. The T-walls will be founded on mainly clayey fill or clayey natural soil down to shallow bedrock with no consistent sand layer. Assessment of these potential failure modes must follow the equations and criteria presented in the Engineer Manual 1110-2-2100 Stability Analysis of Concrete Structures (USACE, 2005) and Engineer Manual 1110-2-2502 Floodwalls and Other Hydraulic Retaining Walls (USACE, 2022). The T-wall sizes were calculated using CTWALL and geometry of the wall was adjusted to reduce overturning and sliding and to decrease the bearing pressure exerted on the soil. The team determined that this PFM is not a risk driver.

A.11. PFM 12: Internal migration into the storm sewer

The focus of this PFM is on the many individual/private storm sewer outlets into the creek. All corrugated pipes will be replaced with concrete pipes during construction and will be recommended to be video inspected every 5 years. Modern construction practices and the short duration of high-water events would

not likely have sufficient duration to initiate and progress a flaw to failure. The team determined this PFM is not a risk driver and was excluded.

A.12.PFM 13: Internal migration into sanitary sewer

The team determined that this PFM is a risk driver, see Chapter 7.

A.13.PFM 14: Internal erosion out of sanitary sewer

This PFM has similar background to PFM 13 but was excluded due to the low likelihood of failure without intervention by means of impacts to water quality as a treatment plant is downstream of the creek. Additionally, the pipe is inspected every 10 years with the results of the last one shown to be in good condition. As such, this PFM is not a risk driver and was excluded.

A.14.PFM 15: CLE along a Pipe

PFM 15 requires a flaw along the length of a pipe crossing under the levee. This deficiency leads to CLE of the material along the pipe, an unfiltered exit on the landside of the levee, hydraulic shear stresses exceed the soil strengths and CLE progresses along the conduit. Material is lost through the unfiltered exit, lowering the level of protection and leading to breach of the levee.

This failure mode was determined to be a non-risk driver based on the construction methods and details that will be required in the construction documents. The construction documents will meet the requirements of and follow the guidance in EM 1110-2-2902. As stated in the EM, 2.3.4.2 PFM-1 Internal Erosion along a Pipe, CLSM will be used along the pipe with a landside filter on the landside end. The CLSM eliminate the common issue with compaction in the haunches and significantly reduce the likelihood of a continues flaw. The landside filter will allow for a filtered exit in the event the CLSM has shrinkage cracks that do allow water to migrate along the pipe. Due to all these considerations, the team determined that PFM is not a risk driver.

A.15.PFM 16: Internal erosion (CLE or BEP) through the levee foundation

As the water surface elevation rises during a flood event, seepage occurs through a continuous (waterside to landside) zone of uniform sand beneath the embankment levee (backward erosion piping or BEP) or through a defect or cracks in the foundation material (concentrated leak erosion or CLE). Levees will be used for risk reduction in place of a floodwall where there is sufficient room for the landside and riverside slopes. For BEP, an unfiltered exit must exist on the landside area. Sufficient seepage forces to detach soil particles in the uniform sand layer at the seepage exit, initiating backward erosion piping. The overlying materials support a continuous and stable roof above the developing pipe. Sufficient horizontal gradients exist for progression of a pipe toward the creek. If detection and intervention are unsuccessful, BEP continues until the pipe connects the creek to the protected area. Gross enlargement of the pipe occurs leading to instability, collapse of the embankment and uncontrolled release of water into the leveed area with associated consequences. For CLE, erosion starts at some defect or crack through the foundation through voids or low density zones. These defects could also be at the foundation/bedrock interface, due to roots of the existing trees, or animal burrows. Erosion of the foundation material could lead to large flows coming from the creek. Enlargement of the seepage path can lead to breach of the structure.

For BEP, a continuous layer of poorly-graded sand needs to exist. The soil profile shows that the subsurface where the levees will be constructed is mainly clayey fill or clayey natural soil down to shallow bedrock with no consistent sand layer. A total of 19 borings have been conducted in the project area, 2 of them were part of the feasibility phase in 2002 and the other 17 in 2023. Only AD-201A shows a layer with poorly graded sand that has a thickness of about 1 foot. The site is generally comprised of undocumented fills underlain by alluvial lean clays. Bedrock was classified as weathered to competent shale and occasional limestone, which ranged from soft to moderately hard. Figure 89 and Figure 90 show the location of a boring and its log, respectively, where a levee will be used for flood control. This is just a small representation of the rest of soil conditions in the project area. The boring log shows mostly clays on top bedrock. The alluvial soils also include silty lean clays, gravelly lean clays, and occasional clays with sand. Seepage analyses were conducted assuming some permeability of the gravel or through cracks in the bedrock. The plan is to excavate a 6-feet-deep inspection trench (Figure 91) below the base of the levee and add a cutoff wall if a continuous pervious zone of sand is found. No seepage berms or relief wells have been recommended for this project. Due to the lack of presence of a continuous sand layer and the construction of a cutoff if one is found, the team has determined that BEP is not likely to occur.

Figure 89. Location of boring ADU-208 where a levee will be used.

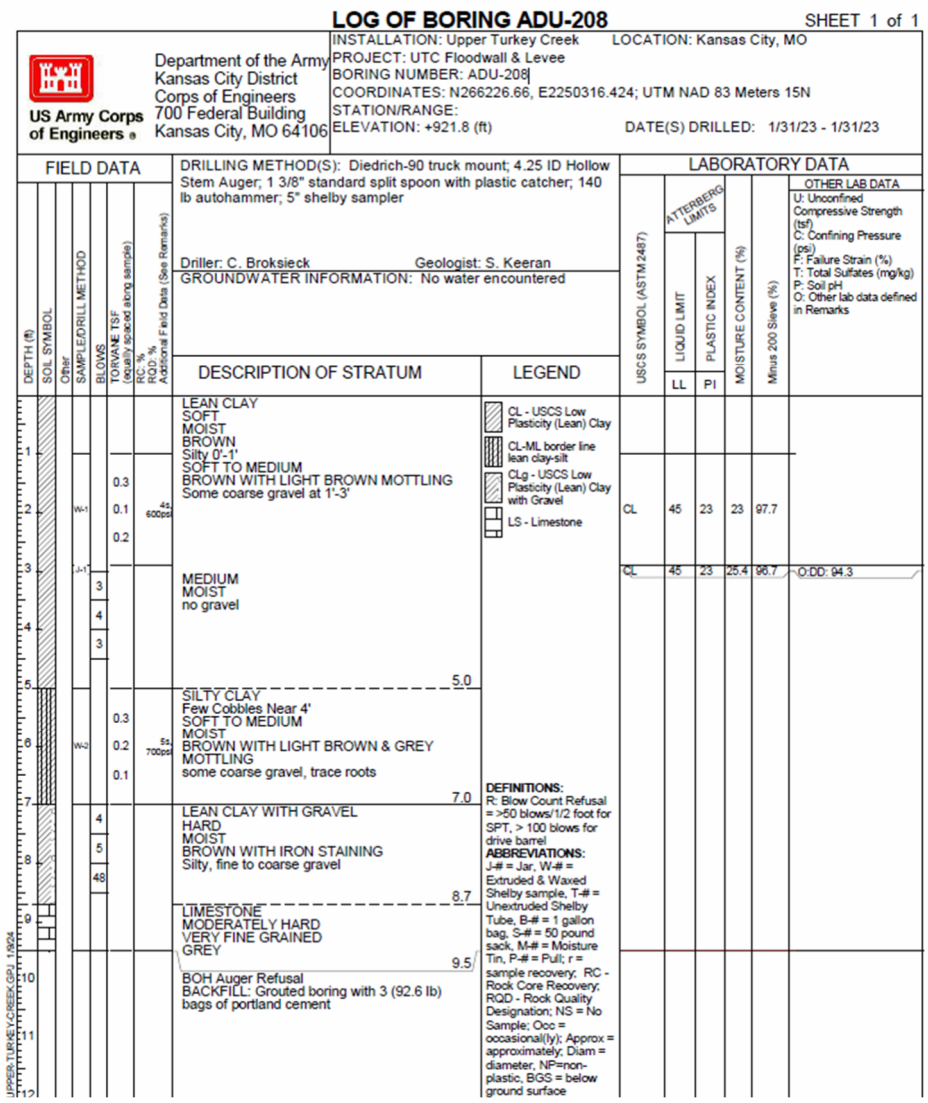

Figure 90. Boring log of ADU-208.

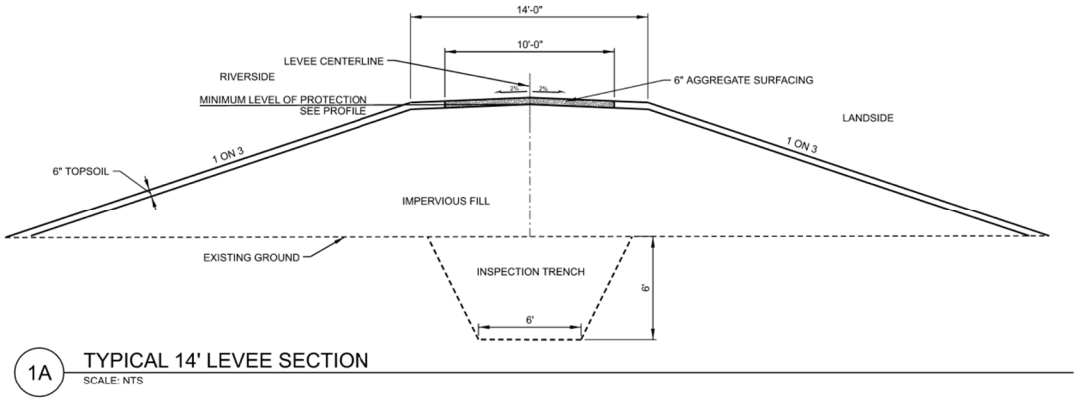

Figure 91. Typical levee section with inspection trench.

For CLE, a void or crack could exist where erosion could start. The fines could maintain the sidewalls of an eroding pipe/crack. There are burrowing animals in the area and the risk assessment team were able to see a groundhog or woodchuck during the site visit on the limestone wall. Extensive burrowing would likely be observed as this area is used daily by the people who use the park or that walk around the area. There are also some trees which roots could provide preferential paths for seepage. While there is a possibility of flaws or defect in the foundation, the short duration would make it unlikely for CLE to progress or continue anywhere between the levee base and the shallow bedrock. Based on these considerations, both CLE and BEP have been excluded as driving the risk in this project.

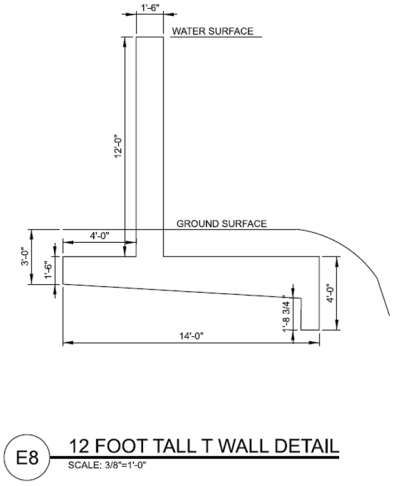
A.16.PFM 17: Internal erosion (CLE or BEP) through I-wall foundation

This PFM is similar to PFM 16, in which internal erosion, whether it is CLE or BEP, occurs beneath within the foundation underneath the flood control structure. Floodwalls will be used for flood risk reduction where there are no sufficient room for a levee. I-walls will be installed in lieu of T-walls wherever possible as long as they meet criteria and have sufficient embedment depth. Sufficient seepage forces detach soil particles and the overlying materials support a continuous and stable roof above the developing pipe/crack. Sufficient horizontal gradients exist for progression toward from the water side to the land side. If detection and intervention are unsuccessful, erosion continues leading to instability and collapse of the I-Wall. Breach of the floodwall causes uncontrolled release of water into the leveed area with associated consequences.

As mentioned in PFM 16, the soil profile in this area is mainly clayey fill or clayey natural soil down to shallow bedrock with no consistent sand layer. BEP would not be possible unless a sand layer is found when excavating. It is possible that CLE could initiate due to voids, joints, cracks, tree roots or animal burrows. I-walls will be embedded into the soil above bedrock if there is sufficient depth that provides resistance against rotational stability. Embedment depth varies in the current design from 12 ft to 20 ft and it could cut off seepage. The short duration of floods would decrease the probability of progression and breach. The team has determined that internal erosion beneath the I-wall is not a risk driver.

A.17.PFM 18: Internal erosion (CLE or BEP) through T-wall foundation

This PFM is similar to PFM 16, in which internal erosion, whether it is CLE or BEP, occurs beneath within the foundation underneath the flood control structure. Sufficient seepage forces detach soil particles and the overlying materials support a continuous and stable roof above the developing pipe/crack. Sufficient horizontal gradients exist for progression toward from the water side to the land side. If detection and intervention are unsuccessful, erosion continues leading to instability and collapse of the T-Wall. Breach of the floodwall causes uncontrolled release of water into the leveed area with associated consequences.



As mentioned in PFM 16, the soil profile in this area is mainly clayey fill or clayey natural soil down to shallow bedrock with no consistent sand layer. BEP would not be possible unless a sand layer is found when excavating. It is possible that CLE could initiate due to voids, joints, cracks, tree roots or animal burrows. However, the short duration of floods would not lead to progression and breach. As part of the design, there was a plan of adding a sheet pile under the T-wall to meet stability criteria that would have also provided a cutoff for seepage. The risk assessment team concluded that adding the sheet pile would not have made the T-wall more stable and that seepage cutoffs were not necessary for the T-wall in the project location due to the soils in the area. The team made the recommendation to remove the sheet pile from the design. The team has determined that internal erosion beneath the T-wall is not a risk driver.

A.18.PFM 19: Instability of limestone wall leads to levee instability

This potential failure mode is dependent on the instability of the limestone wall destabilizing a segment of the earthen embankment. The limestone wall, found lining both sides of the channel, is a gravity block wall built between the 1960s and 1980s. The blocks are approximately 6 feet long, 2 feet deep, and 14 to 18 inches tall and are stacked with approximately 2 inches of offset from the block below (sloping away

from the channel). The wall is maintained by the Merriam Drainage District who estimates 10 percent of the wall has been replaced since its original construction.

The earthen embankment segments of the levee are being designed with a setback from the channel as far as feasibly possible to eliminate instability concerns with the levee that may arise if the block wall collapses. In areas where a sizeable setback is not achievable, the levee alignment will be such that a projected line from the riverside levee toe, with a 1V:3H slope, will not intersect with the face of the block wall. The slope stability analyses will be modeled without the presence of the limestone block wall and will instead show the 1V:3H projected line from the base of the block wall to the ground surface riverward of the levee. The conservatism in choosing to not model the limestone block wall should eliminate concern that a collapse of the wall could lead to instability of the earthen embankment. For this reason, this potential failure mode was excluded.

A.19.PFM 20: Instability of limestone wall leads to I-wall instability

This potential failure mode is dependent on the instability of the limestone wall destabilizing a segment of the I-wall. The limestone wall, found lining both sides of the channel, is a gravity block wall built between the 1960s and 1980s. The blocks are approximately 6 feet long, 2 feet deep, and 14 to 18 inches tall and are stacked with approximately 2 inches of offset from the block below (sloping away from the channel). The wall is maintained by the Merriam Drainage District who estimates 10 percent of the wall has been replaced since its original construction.

The I-wall segments of the levee will be designed with a minimum setback from the channel such that a projected line from the riverside edge of the base of the floodwall, with a 1V:2H slope, will not intersect with the face of the block wall. In the stability modeling, the analyses will be developed without the presence of the limestone block wall and will instead show the projected line from the base of the block wall to the ground surface. The conservatism in choosing not to model the limestone block wall should eliminate concern that a collapse of the wall could lead to instability of the I-wall. For this reason, this potential failure mode was excluded.

A.20.PFM 21: Instability of limestone wall leads to T-wall instability

This potential failure mode is dependent on the instability of the limestone wall destabilizing a segment of the T-wall. The limestone wall, found lining both sides of the channel, is a gravity block wall built between the 1960s and 1980s. The blocks are approximately 6 feet long, 2 feet deep, and 14 to 18 inches tall and are stacked with approximately 2 inches of offset from the block below (sloping away from the channel). The wall is maintained by the Merriam Drainage District who estimates 10 percent of the wall has been replaced since its original construction.

The T-wall segments of the levee are being designed with a minimum setback from the channel such that a projected line from the riverside edge of the floodwall's footing, with a 1V:2H slope, will not intersect with the face of the block wall. In the stability modeling, the analyses will be developed without the presence of the limestone block wall and will instead show the projected line from the base of the block wall to the ground surface. The conservatism in choosing not to model the limestone block wall should eliminate concern that a collapse of the wall could lead to instability of the T-wall. For this reason, this potential failure mode was excluded.

A.21.PFM 22: Seismic instability of levee or wall

The project area is in a region of low seismic activity but has some potential sources at over 100km from the project site. Due to the shallow nature of the overburden above bedrock and the likelihood of the floodwalls being founded on piles resting on bedrock, the likelihood of an event with a great enough magnitude to cause disturbance, the lack of liquefiable sands, and the low probability of a high water event and a co-seismic event, this potential failure mode was excluded.

A.22.PFM 23: Riverine erosion of levee toe/face leads to breach

The slope and conveyance of the creek during flood flows is expected to result in high channel velocities of greater than 16 ft/s and still relatively high velocities in the overbank of greater than 9 ft/s. These overbank velocities are sufficient to remove vegetative cover and initiate erosion in all embankment material types. However, the flow-depth and shear stresses are relatively low and are unlikely to cause significant damage, given the short duration of flooding above the banks (less than 2 hours). The current plan calls for riprap armoring between the limestone block wall and the levee which would mitigate erosion in this zone. The face of the levee itself may have some damage from a flood, but progressing to a full breach is unlikely. Figure 92 shows estimated velocities at one location in relation to the levee.

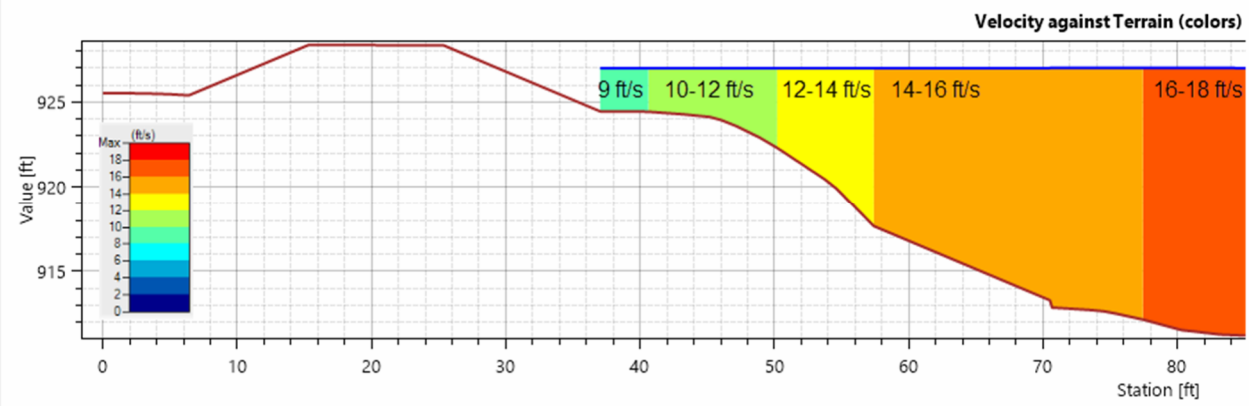


Figure 92. LB Sta 30+30 velocity estimates.

A.23.PFM 24: Riverine erosion of T-wall foundation and breach

Similar to the previous PFM, velocities are estimated to be high in the overbanks, but depths, shear stress, and duration are limited during peak flood conditions. The overbank area between the limestone block wall and the floodwall is planned to be armored with riprap. Erosion in this area is not expected if sufficiently armored. The wall is also designed to be stable if the block wall fails and some amount of creek-side material is eroded. A full failure of the wall from erosion is unlikely to progress during the short duration of peak flood conditions. Figure 93 shows velocity estimates at one location in relation to the floodwall.

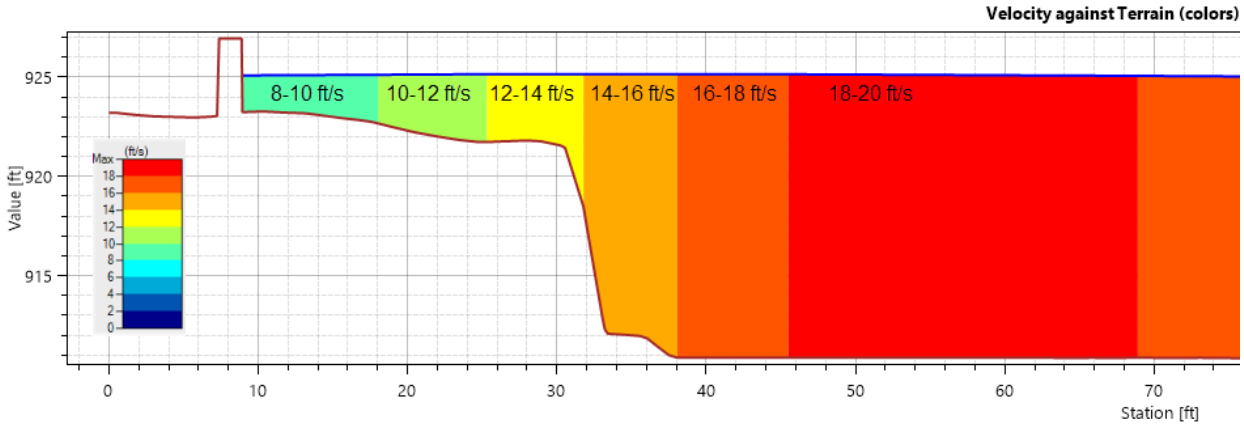

Figure 93. RB Sta 11+20 velocity estimates.

A.24.PFM 25: Riverine erosion of I-wall foundation and breach

Similar to the previous PFM, erosion of the foundation is planned to be mitigated through riprap armoring that withstands the estimated velocities. It is unlikely that the limestone block wall and a significant amount of the foundation are eroded during the short duration of peak flooding.

A.25.PFM 26: Failure of Johnson Drive Bridge Due to Uplift

Replacement of the Johnson Drive bridge is planned as part of the project. The bridge will be designed to AASHTO and city requirements and for USACE stability requirements. The design will be required to meet the stability requirements of EM 1110-2-2100 for the top of protection loading and the likelihood of failure due to uplift will be negligible and this failure mode is considered a non-risk driver.

A.26.PFM 27: Debris impact failure of a floodwall or bridge acting as a flood risk feature

Debris may be present in the channel and from overland sources before and during a flood event. This could be in the form of small vegetation, large woody debris, and anthropogenic sources. While the team expected debris to be present and to get hung up on features that protrude into the flow (e.g., pedestrian bridges), it is estimated that debris is unlikely to cause significant forces on levees or walls to a point of leading to breach. Floodwalls are designed with some debris loading forces incorporated and levees are largely not affected by debris due to the large size, sloping surface, and lower velocities away from the center of the channel. Debris is more likely to be carried in the center of the channel where velocities are highest and are unlikely to move away to lower velocity zones along the FRM features with any significant force associated.

A.27.PFM 28: Pedestrian bridge fails and impacts wall/bridge/levee resulting in breach

The pedestrian bridges are expected to be submerged and/or overtopped during large flood events. The high channel velocities of greater than 18 ft/s and any sources of debris are expected to put large forces on the bridges to a point that could lead to failure. If a bridge fails and is removed from its foundation, the bridge structure could be carried downstream and impact one of the project features, resulting in a breach. These bridges were not designed to support flood and debris flows associated with this FRM project and the team estimated that they may not withstand a major flood. Figure 94 shows an example of what this type of loading may look like for a bridge in Minot, ND during the 2011 flood event.

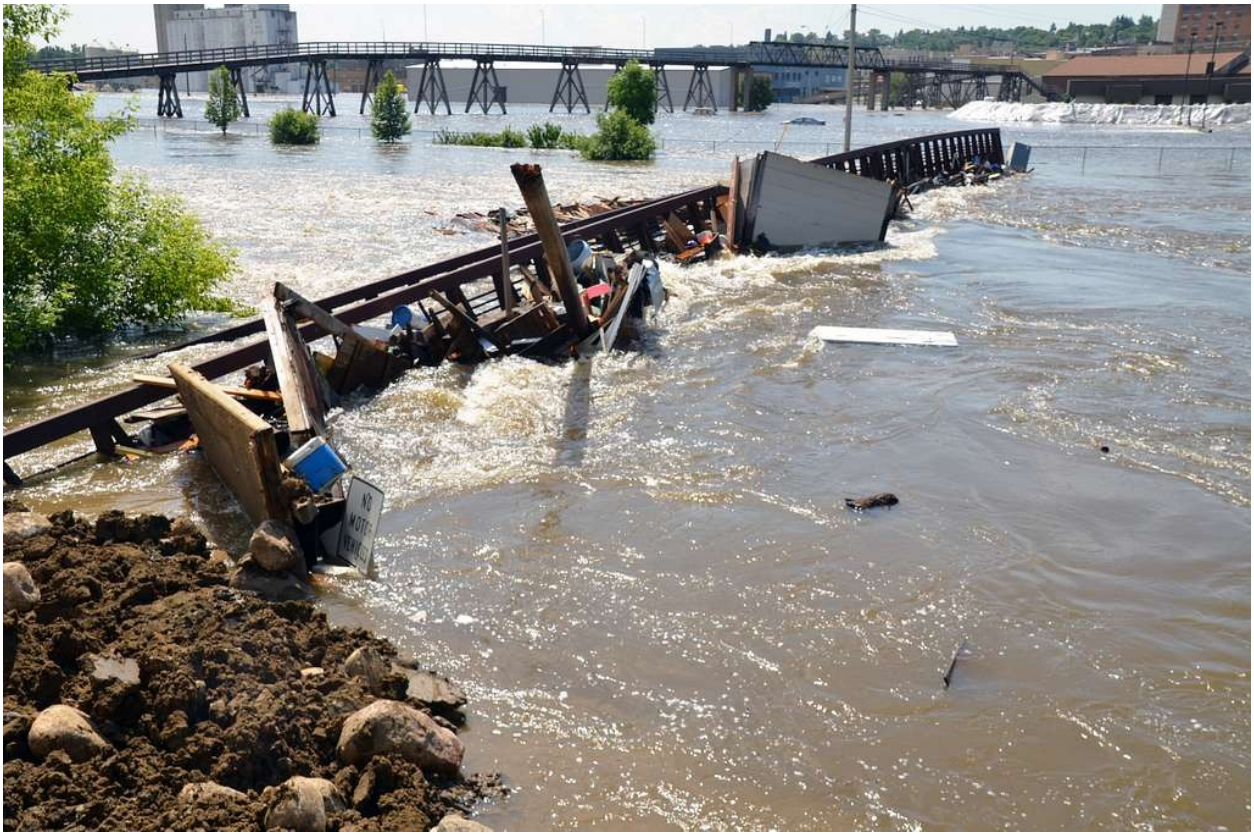

Figure 94. Photo of a pedestrian bridge in Minot, North Dakota during a flood in 2011 (https://nara.getarchive.net/media/a-pedestrian-bridge-that-fell-into-the-souris-river-c1e0cb?zoom=true)

In the case of the Minot flood, the bridge was expected to fail from the debris. Emergency management teams considered and tried to remove the bridge in anticipation of a failure but were unsuccessful. Ultimately, the bridge withstood the forces and did not fail. While the bridges at this project may not withstand similar forces, the team estimated that a failure of the bridge is unlikely to be redirected into a significant impact force against a levee or floodwall. It is likely that the bridge would be carried in the highest velocity zone at the center of the channel, if at all. A bridge failure and associated debris would likely be more of a concern of blocking downstream bridge openings, resulting in increased stages.

A.28.PFM 29: Channel erosion undermines limestone wall and fails the levee or wall

Channel erosion is a natural process for the creek that can be observed by the presence of small waterfalls within this reach, where layers of limestone and other rock of varying integrity will eventually experience differential erosion of softer layers leading to the vertical drop in the channel. Deposition of fine to medium grain material is present during low flows but is likely to be mobilized during peak flood flows. Long term flows and moderate to high flows can cause continued erosion of channel bedrock material and undermining of the limestone block walls, which is of greater concern to the levee and floodwall as a failure of the limestone block wall could progress to a point that could compromise the stability of those features. Figure 95 shows an example of depth-averaged velocities from the two-dimensional model and the relation to the limestone block wall and proposed floodwall. The block wall has experienced some undermining erosion in the past which has been responded to through repair projects by the drainage district in replacing blocks and sometimes placing concrete. These are likely related to long term flows and moderate flows. The concern for levee risk is that a single event undermines the block wall and erodes a significant amount of material. It is unlikely, given the short duration of storm events, that enough material could be removed to compromise the levee or floodwall stability. The design accounts for this through setting back the features so that some amount of erosion can be tolerated. If damage does occur to the block wall during a flood, the local sponsor should be inspecting and maintaining the blocks to ensure stability prior to the next flood event.

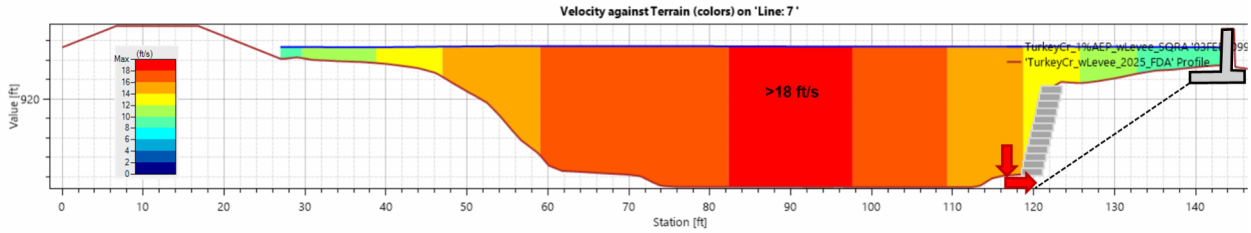

Figure 95. LB Sta 51+00 and RB Sta 10+00

A.29.PFM 30: Structural Failure of I-wall

This PFM is a concrete or sheet pile failure of an I-wall. This requires a major failure and near collapse which drops the top of the protection. As required and as stated in chapter 9 of the DDR, the I-walls will be designed for all applicable load cases in accordance with EM 1110-2-2502 and EM 1110-2-2104. By designing to meet the structural criteria, the likelihood of a structural failure is negligible, and the PFM is considered a non-risk driver.

A.30.PFM 31: Structural Failure of T-wall

The structural failure modes of a T-wall are similar to an I-wall and will be mitigated by following appropriate criteria. Refer to PFM 30.

A.31.PFM 32: Vehicle impact failure of I-wall

The likelihood of this failure mode to coincide with a high-water event is low. Structures are designed to withstand forces from barges and will be designed to consider vehicle impacts. This PFM is considered a non-risk driver since impacts will be a consideration of the design.

A.32.PFM 33: Tree next to the floodwalls/levees topples and leads to instability

This PFM is regarding a tree toppling and damaging any of the levees or floodwalls. If there is significant damage to the levee or floodwall and a high water event happens before any repairs, water could erode the exposed area or the elevation of protection could decrease if the floodwall is pushed. These damages could lead to breach of the levees or floodwalls during a flood event. The USACE policy has been to keep levees “vegetation free” on both slopes, crest and 15 feet away from the landside and waterside toes. The recommended vegetation cover for the levees has always been mowed grass. This is due to the uncertainty of how trees, shrubs and other vegetation could interact with the levees. Also, vegetation makes it harder for inspections and intervention. For floodwalls, policy has been to keep a “vegetation free” zone of 15 feet away from the wall (minimum) on the land side and water side. In addition, there is an 8 feet horizontal clearance from the wall foundation. Lastly, there is a vertical clearance of 8 feet above the top of the floodwalls. There are existing trees where the levees and floodwalls will be constructed both toward the land side and water side. Also, there is vegetation and trees that have grown right on top of the limestone wall as seen in Figure 96.

Figure 96. Vegetation along the Upper Turkey Creek.

The USACE has recently adopted risk-informed design process that could allow vegetation other than grass on levee, mainly on the waterside slope and waterside toe. This process requires evaluation of what type of vegetation will be planted and its associated risks. There have been no requests for leaving existing trees in place where the levees and floodwalls will be at the moment when this risk assessment was conducted. It could be possible that people that live near the park could want to leave some of the trees in place where levees will be constructed. A waiver would be needed allowing for vegetation, which depend on the results of another risk assessment. While a waiver could be requested for levees after conducting a risk assessment, best practices for floodwalls is to retain the minimum vertical and horizontal clearance distances in which there should be no trees or woody vegetation. Only grass or other small herbaceous vegetation could be allowed as long as the roots do not cause damage to the walls. This PFM was determined to be a non-risk driver if existing trees are removed and vegetation is cleared within the vegetation free zones or if they are outside of the required distances.

A.33.PFM 34: Wind-wave erosion of the levee

Wind-waves can develop over bodies of water with appreciable wind fetches, which then can break on the slope of a levee and cause significant erosion. If this erosion occurs for a sufficient duration and location, it could progress through the levee and result in a breach. The narrow, winding creek channel does not allow for long wind fetches to become apparent and would require specific wind directions for any fetches longer than the floodplain width of 100-500 feet. Also, high-velocity, turbulent flows may disrupt wave growth in the transverse direction to the flow. While a storm that generates peak flood flows may be associated with stronger winds, it is unlikely that peak winds coincide with peak water levels that would erode the narrowest part of the levee. Given that the duration of loading above the levee toe is expected to be less than a few hours, it is unlikely that the duration of any impact forces from small wind waves would cause enough erosion to progress to failure. Given the very short duration and low probability of coincident, adverse wind conditions during the short peak, it is unlikely that any wind-wave damage would occur to the levee and extremely remote that it would result in a full breach.

A.34.PFM 35: Internal erosion out of pressurized pipe

For this PFM, pressurized pipe ruptures within or under the levee or floodwall. Escaping fluid causes internal erosion sufficiently that the levee crest or top of floodwall is impacted and eventually lowered below the flood water level. Overtopping occurs and leads to breach.

The risk assessment team was informed that there are water and gas pipes in the ground where the levees and floodwalls will be constructed. Size and lengths of these pipes can vary. To cause major issues to the levee that could lead to its breach, a rupture of one of these pipes would have to go unnoticed. Loss of pressure due to rupture is independent from low water or flood events. As these pipes operate constantly and are heavily monitored, the likelihood of any of them experiencing a major rupture that could cause erosion issues to the levee are considered remote. The loss of pressure would be identified by the public agencies and would have to address the issue quickly. Some of these utility pipes are planned to be relocated. Others will be modified to replace their material. The team recommends valves on both sides of the levees for pressurized pipes that go through the levee embankment or its foundation. The team has determined this PFM is not a risk driver.

A.35.PFM 36: Bridge construction leads to increased water levels for the existing conditions

If care is not taken during construction of the bridge replacements, a condition could be created which increase the existing condition flood risk above current levels. For example, a full-height cofferdam that blocks half of the channel could result in increased water level impacts upstream of the bridges and, for certain flood events, could result in life safety or economic consequences that would not have been experienced with the existing bridge having full conveyance. The current plan is that bridge replacements will occur before the construction of the rest of the project including levees and floodwalls, so the flood risk management features will not be in place to mitigate some of the effects of bridge construction during a major flood. The primary factor that reduces the risk of this PFM is that normal water levels in the channel are typically only a few feet in depth, so the dewatering features associated with bridge construction are likely to have minimal impact on conveyance. While a flood could occur at any time and impact the dewatering and construction efforts, it is likely that the impact to upstream water levels is minimal.

A.36.PFM 37: Flap Gate stuck closed leads to excessive ponding

PFM 37 occurs if debris or sediment settled on the outside of a flap gate which does not allow drainage of the flap gate and leads to excessive ponding during an extreme storm event on the interior. This failure mode is a non-risk driver because it does not lead to uncontrolled flow into the levee system, only prevents drainage. Additionally, the sponsor should be ensuring there is clearance for the flap gates to open during flood events as part of routine operations and maintenance. Having two forms of closure does not prevent riverside flap gates from being pinned closed causing ponding of the interior and so this PFM does not factor into the single closure recommendation.

As also stated in PFM 6, it is recommended that during routine visual inspections of the levee system, that the sponsor clear any sediment or debris that would prevent opening of the flap gates.

A.37. PFM 38: Global Instability of Shawnee Mission Parkway roadway embankment east of Turkey Creek.

PFM 38 occurs if loading of the upstream side of the Shawnee Mission Parkway embankment is sufficient in both loading height and duration to reduce shear strengths of the embankment soils, causing a slide and lowering of the embankment height which would allow an uncontrolled release of flow into the leveed area.

The portion of Shawnee Mission Parkway to the east of Turkey Creek acts as a non-project feature in the flood protect system. The roadway embankment prevents flow from entering the leveed area after the levee and floodwall has already tied into the downstream side of the roadway embankment as shown below in Figure 97. This PFM was excluded due to the significant freeboard of 11 feet for the top of levee loading scenario between the upstream depths and roadway crest. Additionally, the roadway embankment is over 200 feet wide which would require significantly longer and higher loadings to saturate soils and reduce sheer strength for any slide to occur.

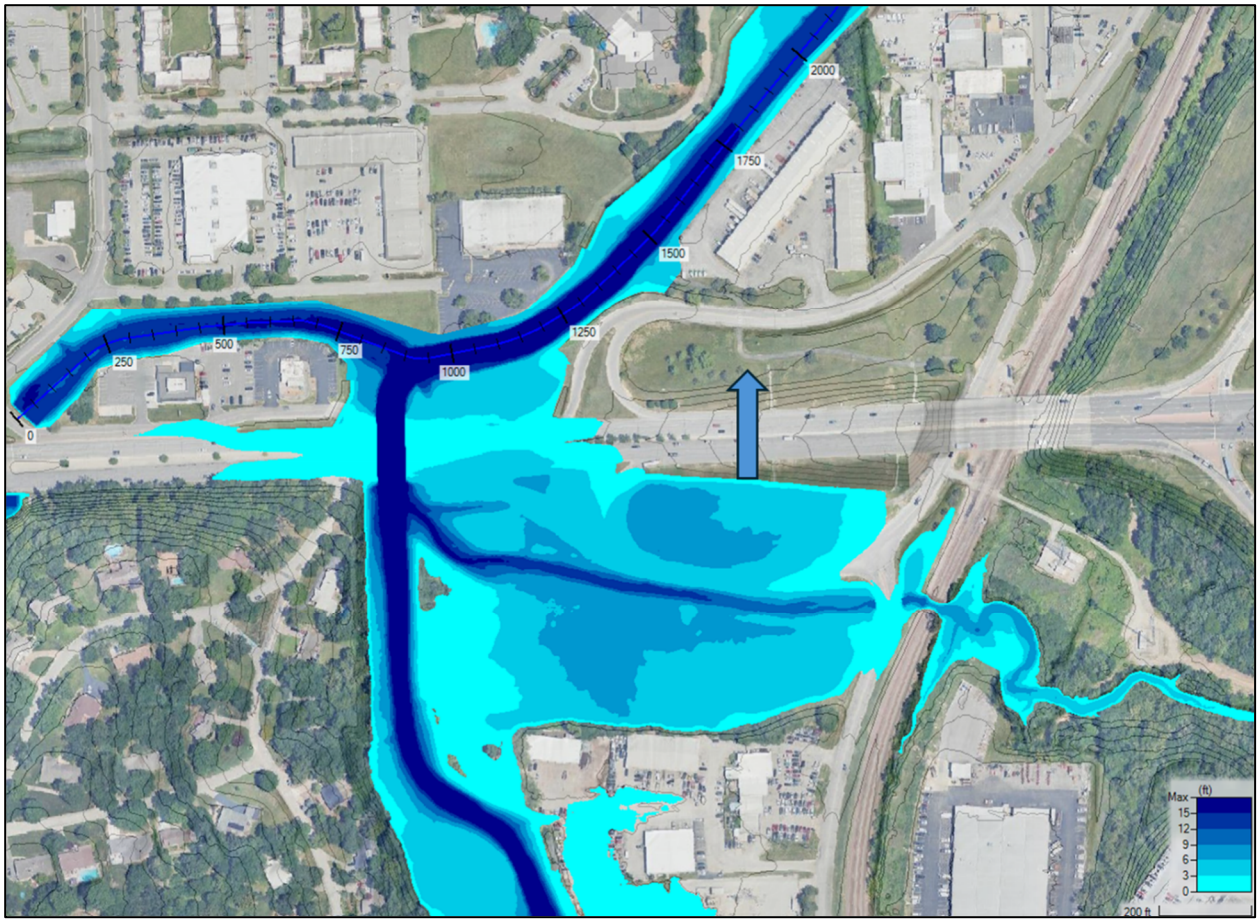

Figure 97. Non-project feature flood protection of Shawnee Mission Parkway roadway embankment.

CENWK-ED 01 February 2026

MEMORANDUM THRU Commander, U.S. Army Corps of Engineer, Northwest Division, (CENWD-RBE/Ms. Rebecca Vandine), 631 Saint Anne St, Suite 100, Rapid City, SD 57701

Chair of SOG (CEIWR-RMC/Mr. David Serafini), 132 E Street, Suite 130, Davis, CA 95616

HQUSACE (CECW-EC/Mr. Rich Varuso), 7400 Leake Ave, New Orleans, LA 70118

FOR HQSACE (CECW-EC/Mr. Travis Tutka), 441 G Street NW, Washington, D.C. 20314

SUBJECT: Design Guidance Deviation for Secondary Closure for Storm Drainage Pipes – Upper Turkey Creek, Merriam, Kansas

1. PURPOSE: This memorandum requests approval for a design guidance deviation requiring secondary closures for storm drainage pipes 36 inches and larger within the Upper Turkey Creek project limits. The closure type requirements for storm drainage pipes set forth in EM 1110-2-2902, Chapter 9, 9.4.1 Gates, states that drainage pipes 36-inches and larger for fast rising floods requires one passive and one active closure. Kansas City District requests a variance to require one passive closure for pipes 36-inches and larger.

2. REFERENCES:

a. EM 1110-2-1413 Engineering and Division, Hydrologic Analysis of Interior Areas, 24 August 2018

b. EM 1110-2-1913 Engineering and Division, Design and Construction of Levees, 30 April 2000

c. EM 1110-2-2902 Engineering and Division, Conduits, Pipes, and Culverts Associated with Dams and Levee Systems, 31 December 2020.

3. BACKGROUND: The Upper Turkey Creek FRM project is located in the City of Merriam, in Johnson County, Kansas. Turkey Creek is a right-bank tributary of the Lower Kansas River located in Johnson and Wyandotte counties, Kansas, between approximate river miles (RMs) 2.7 to 3.7.

There are approximately 17 existing gravity drainage crossings under the proposed levee/floodwall. The portion of the existing drainage pipe crossing the levee or floodwall

limits will be replaced with reinforced concrete pipe (RCP) and any existing pipes smaller than 24-inch will be upsized to 24-inch with this project.

EM 1110-2-2902, Conduits Pipes and Culverts Associated with Dams and Levee Systems lists the closure type requirements for different flood rise conditions. The flood rise condition for our project is considered fast since there is less than 12 hours of prediction time. The Project Delivery Team (PDT) recommends a deviation from Table 9-1 of EM 1110-2-2902 to use one passive closure at the outlet for all pipes including those greater than or equal to 36 inches. This recommendation affects 8 of the 17 drainage crossings.

4. IMPACTS AND BENEFITS: This deviation would present an opportunity to reduce the operation and maintenance impacts for the Sponsor without increasing incremental project risk. This deviation also reduces the risk of the Sponsor closing an active gate and impounding water on the interior longer than it would have otherwise remained under full passive conditions. The risk to life safety from backflow through an open pipe is zero, and the economic damages related to backflow are minimal as backflow would only lead to small incremental differences in the interior ponding depths in isolated areas.

5. RISK ASSESSMENT: The design guidance deviation was evaluated as part of the Semi-Qualitative Risk Assessment (SQRA) and documented in the SQRA Report (2025). There were 37 potential failure modes (PFMs) identified by the team. Below, Table 1 summarizes the list of PFMs with a short description. The risk assessment concluded that the design deviation does not increase the incremental life safety risk and can be adopted without negatively impacting the risk characterization associated with the project. The risk matric for the project including the proposed deviation is shown in Figure 2.

Table 1. Potential failure modes.

Potential Failure Mode	Risk Driver?	Description
PFM 01	Yes	Overtopping breach of the levee
PFM 02	No	Overtopping breach of the floodwall
PFM 03	No	Concentrated leak erosion through the embankment between construction lifts
PFM 04	No	CLE along differential settlement
PFM 05	No	CLE along levee/wall/bridge interfaces
PFM 06	No	Flap gates stuck open resulting in backflow (for pipe >36", assuming one flap gate per pipe)
PFM 07	Yes	Global instability of the levee

Potential Failure Mode	Risk Driver?	Description
PFM 08		Global instability of the I-wall
PFM 09		Global instability of the T-wall
PFM 10	No	Local instability of the I-wall
PFM 11	No	Local instability of the T-wall
PFM 12	No	Internal migration into the storm sewer
PFM 13	Yes	Internal migration into sanitary sewer
PFM 14	No	Internal erosion out of sanitary sewer
PFM 15	No	CLE along a pipe
PFM 16	No	CLE or BEP through the levee foundation
PFM 17	No	CLE or BEP through I-wall foundation
PFM 18	No	CLE or BEP through T-wall foundation
PFM 19	No	Instability of limestone wall leads to levee instability
PFM 20		Instability of limestone wall leads to I-wall instability
PFM 21	No	Instability of limestone wall leads to T-wall instability
PFM 22	No	Seismic instability of levee or wall
PFM 23	No	Riverine erosion of levee toe or levee face
PFM 24	No	Riverine erosion of T-wall foundation
PFM 25	No	Riverine erosion of I-wall foundation
PFM 26	No	Failure of Johnson Bridge due to uplift
PFM 27	No	Debris impact failure of wall/bridge
PFM 28	No	Pedestrian bridge fails and impacts wall/bridge/levee
PFM 29	No	Channel erosion undermines limestone wall and fails levee/wall
PFM 30	No	Structural failure of I-wall
PFM 31	No	Structural failure of T-wall
PMF 32	No	Vehicle impact failure of I-wall
PMF 33	No	Tree next to the floodwalls/levees topples and leads to instability
PMF 34	No	Wind-wave levee erosion
PMF 35	No	Internal erosion out of pressurized pipe
PMF 36	No	Bridge construction leads to increased water levels for existing conditions
PMF 37	No	Flap gate stuck closed leads to excessive ponding

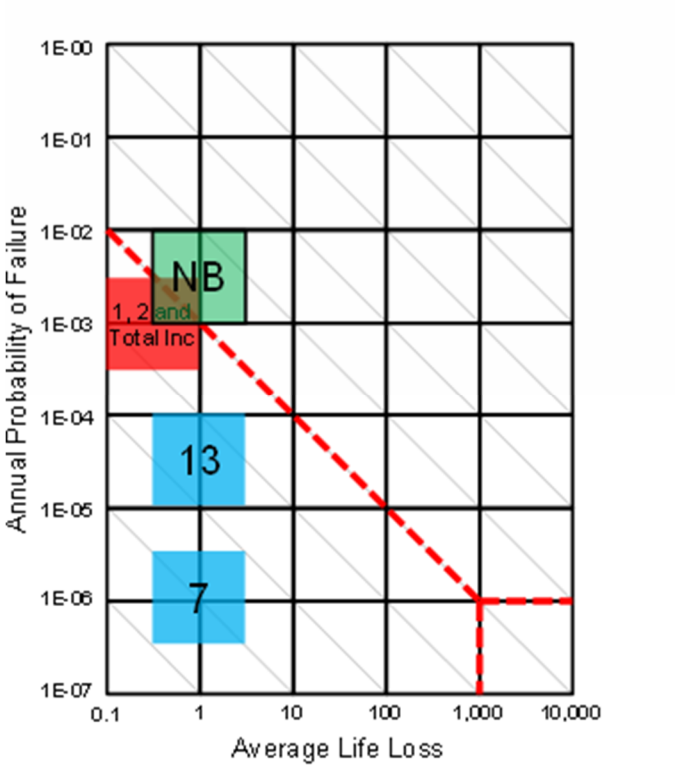

Figure 2. Societal Incremental Life Safety Risk Matrix.

The team identified one potential failure mode (PFM 6) in which one passive closure was directly involved by initiating or progressing failure. The PFM discussed below was evaluated and characterized as a non-risk driving PFM.

a. PFM 6: FLAP GATE STUCK OPEN RESULTING IN BACKFLOW INTO LEVEED AREA: PFM 6 occurs if debris were to pin open a flap gate during high channel stages and allow uncontrolled backflow into the leveed interior. Channel water surface elevations higher than the landside drainage structure inlet inverts would produce hydraulic head necessary to backflow into the interior area. Flow could back up through curb inlets, the detention pond drop inlet, or daylighted conduits depending on which flap gate gets pinned open.

   This failure mode was determined to be a non-risk driver for a number of reasons. Most of the drainage structures are outlets to underground stormwater systems, and thusly, limits the size of any debris that could pin open a flap gate from the inside as it would likely need to pass through a curb inlet or similar structure. Additionally, the pipes have slopes ranging from 0.66% to 5.45% slopes and are likely to be self-cleaning which reduces the likelihood of sediment buildup that could prevent flap gate

closure. Large sources of debris from the river, such as logs or branches are unlikely to prevent closure of the flap gates because the river would still need to be at a low/moderate stage for flap gates to be partially open and draining interior flow which would not have the velocities and energy to sweep debris downstream. During higher stages that do have the capability to sweep trees downstream, the flap gates would already be well submerged and pinned closed due to the water pressure.

It is recommended that the sponsor inspect the flap gates visually multiple times a year during routine inspections and/or after large storms or flood events which exceed the monitoring stage of 14-feet at the Turkey Creek at Johnson Drive StormWatch gage (TU04). These visual inspections should be conducted to ensure the flap gates are free of debris and functioning properly.

It is recommended to proceed with one passive closure for each drainage structure, including outfalls greater than 36-inches in diameter. Active closures are not viable alternatives given the flashy nature of the system and the lack of flood forecasting capabilities for the watershed. There also runs a risk of closing a gate well and impounding water on the interior longer than it would have otherwise remained under full passive conditions. The risk to life safety from backflow through an open pipe is zero, and the economic damages related to backflow are minimal as backflow would only lead to small incremental differences in the interior ponding depths in isolated areas. Two specific drainage structures along the project were analyzed. The first is a drainage structure (St-15) on the left bank with the flap gate fully stuck open for the duration of the top of levee loading. A majority of the inundation on the interior is less than 2 feet with only two structures seeing a minor impact. The second is drainage structure (ST-20) on the right bank with the flap gate being fully open which allows backflow into downtown Merriam. Backflow into the interior is mostly contained to the streets or parking lots, but some buildings do see inundation of 2 feet or less.

6. SUMMARY: Based on the SQRA, the proposed design guidance deviation does not impact the incremental project risk and the project risk will remain below tolerable risk guidelines. The design guidance deviation was presented, and findings were briefed to the RID Group on May 20, 2025. Based on the SQRA findings, Kansas City District recommends approval of the design deviation described in this memorandum.

7. POINT OF CONTACT. Please contact Zack Young, NWK LSPM, at (816) 389-3042 or zackary.j.young@usace.army.mil regarding this matter.

CENWK-PMC-J 19 November 2024

MEMORANDUM FOR RECORD
SUBJECT: *Upper Turkey Creek Design Charrette Summary*

1. The purpose of this memorandum is to document the activities, discussions and conclusions from the Design Charrette that was performed for this project early in design. The Design Charrette was focused on the downtown reach of the project, between Johnson Drive and where the creek crosses Merriam drive to the north.

2. **2023 Efforts.** During some early meetings with the City of Merriam, it was decided that additional alternatives to the feasibility study recommended plan needed to be considered in order to align with the city's goals for the downtown reach of the project. The Design Charrette initial meeting was held 23-24 August 2023. The agenda and list of participants can be found in the attachments. The objective was to develop concepts that meet the city and USACE objectives and to select a preferred concept. During this meeting the city and USACE presented the concepts developed by the city in recent years before this project started and USACE presented the recommended plan. Then the group developed city and USACE priorities. These priorities are as follows:

- CITY PRIORITIES
    1. Incorporates city vision for downtown – not in FEMA regulated floodplain – developable.
    2. Creek as an amenity / visual and physical access / connectivity
    3. Green space and trails on east side of creek
    4. Optimize project value
        - » Coordinate with Merriam Drive current redevelopment plans (construction planned for 2024)
    5. Preserve Market Place (in floodplain as-is is ok or relocate if needed)
    6. Consider preserving South end of downtown buildings (LOW)
- USACE PRIORITIES
    1. Reduce flood risk for the whole area identified during feasibility study
    2. Minimize or eliminate USACE processes to re-evaluate (time and money)
        - » PACR already likely (cost)
        - » LRR at most (scope)
    3. Work with nonfederal partner – rework the original plan as needed to coordinate with development
    4. Minimize project cost

Other important considerations were to maintain creek access for maintenance and access for the sanitary sewer and possibly other utilities for maintenance.

Then the team split into groups and developed some concepts to align with the city and USACE priorities. Ten concepts were developed and they are included in this report as an attachment. Additionally, each concept was presented and reviewed as a group and the results of those

discussions and conclusions are also included in a table and other notes at the end of the concepts in the attachment. The group concluded to further develop alternatives 1b, 2b, 6, 7a and 7b. The H&H modeling of these 6 concepts that progress thru a sequence in order to see how the model responds with the incremental changes. The alternative that reaches the level needed for levee certification is the city's preferred alternative. The following was the 6 concepts, #3-#8 modeled, refer to the attachments for more details of each alternative.

Six Concepts modeled for the Design Charrette

3. 2024 Efforts. The alternative concepts were modeled in HEC-RAS the fall of 2023. There were some intentional delays as we waited for the Johnson County modeling to be completed, but due to delays in those efforts, we decided to proceed with developing these with the USACE hydrology in late 2023. Upon completion of the H&H modeling, the group reconvened on 5 March 2024 to review the findings and with the objective to make a decision going forward for design.

The results of the eight concepts were not giving the results that met the project priorities. Plan views and cross sections of H&H results for the eight concepts are in the attachment. Benching was somewhat limited in order to ensure sedimentation doesn't become a maintenance issue. Channel benching or channel widening causes flow to slow down and material drops out and deposits in the creek bed. Then eventually vegetation grows and becomes harder to displace by the water in a flood event. For these analyses, benching was limited to an estimated 2-year elevation.

Benching alone, concepts #3-#6, was not sufficient to provide the required level of protection. Concept #7 included benching with a levee along Merriam Drive, resulted in a taller levee than was preferred. Concept #8, which added some additional benching downstream of the Merriam Drive Bridge on the right bank, required shorter levees than #7.

All the alternatives required significant real estate acquisition along the west side of Merriam Drive and did not result in significantly lower or no levees along this reach. As a result, the group concluded to maximize available real estate out of the floodplain and to minimize negative impacts to the benefit-cost ratio, keeping the levee along the feasibility alignment was preferred. Additional considerations for the team were to maximize the levee extents in the downtown reach versus floodwall and to further investigate benching downstream of the Merriam Drive Bridge on the right bank and possibly channel widening north of Johnson Drive to further reduce the height of the levees and floodwalls in the downtown reach.

4. Conclusion. The project will remain on the alignment established in the feasibility study recommended plan since the concepts' impacts to real estate are substantial without much impact to the levee and floodwall heights through the downtown reach of this project. The project will likely have levees and floodwalls taller than the 3-foot objective, however the team will consider

benching downstream of the Merriam Drive Bridge on the right bank and possibly channel widening north of Johnson Drive during design to further reduce the height of the levees and floodwalls in the downtown reach.

2023 AGENDA

CHARRETTE AGENDA Upper Turkey Creek - Merriam, KS		
FOCUS AREA: Johnson Drive North to the Merriam Drive creek crossing		
Charrette Objectives: PRIMARY: The purpose of the charrette is to develop concepts that meet project objectives and select a preferred concept that provides enough information to make decisions to proceed with into the design phase. SECONDARY: (1) Delineate USACE cost shared project from city street and development projects (2) Include conceptual construction phasing AND impacts to local activities (farmers market, car show, etc)		
Time	**Wednesday, August 23** USACE - 601 E 12th St, KCMO Room G41	**Thursday, August 24** USACE - 601 E 12th St, KCMO Room G41
0830	Building entry and Assemble	Building entry and Assemble
0900	**INTRODUCTIONS**	**Review Hybrid Concepts Developed on Day 1 - likes and dislikes - select 1-2 to develop further**

UPPER TURKEY CREEK - EVALUATION

	carry forward?	LIKE	DON'T LIKE	RISKS	DESCRIPTION
1	no, 1b better	increasing green space and creek as an amenity; lower levee height because setback; farmers market next to amphitheater; opening up floodplain; only touching Merriam drive once; not as much SS relocation; city project - move road and relocate utilities ahead of flood reduction project	increases length of flood protection; don't gain much from bumpout to justify lengthening flood protection; less developable, more maintenace of green space; still need detention basin; loose historical buildings near johnson drive; adding buyouts and may not offset costs of flood protection; floodprotection hides the public spaces; utilities - would want more road and levee separation to allow for utility easements and eats into development space	more cost for merriam drive to be relocated now as part of this project; relocating merriam drive impacts developable area;	includes benching and new longer Merriam Drive bridge; eliminates buildings in old downtown; assumes relocated Merriam drive (but could keep Merriam Drive on current alignment too); assumes no buildings/development riverside of the new alignment
1b	yes	increasing green space and creek as an amenity; lower levee height because setback; farmers market next to amphitheater; opening up floodplain; only touching Merriam drive once; not as much SS relocation; city project - move road and relocate utilities ahead of flood reduction project; decreases length of floodprotection over 1a; more efficient hydraulically	less developable, more maintenace of green space; still need detention basin; loose historical buildings near johnson drive; adding buyouts and may not offset costs of flood protection; floodprotection hides less public spaces than 1a; utilities - would want more road and levee separation to allow for utility easements and eats into development space (a little less than 1b)	more cost for merriam drive to be relocated now as part of this project; relocating merriam drive impacts developable area;	same as 1
2	no, 2b better	increasing green space not as much as 1a/b; keeps old downtown - mix of old and new; lower levee height because setback; more levee than floodwall from FS plan; farmers market next to amphitheater; opening up floodplain not as much as 1a and b; only touching Merriam drive once	less developable, more maintenace of green space; still need detention basin; adding less buyouts than 1; floodprotection hides less public spaces than 1a	bridge relocation forces the city to relocate the road and negates the need to update merriam drive now	city doesn't need to relocate the bridge; USACE doesn't need to relocate the bridge; needs longer or overtopped for this project now
2b	yes will consider preserving old downtown area and replacing bridge on current alignment	no merriam drive relocation needed and city can decide what to do with Merriam drive			levee with separation of 15ft from merriam drive; no relocation of bridge but lengthing bridge still
3	no	maximizes developable area; levees less costly than levees and floodwalls; similar to FS - very little change to the authorized project	road next to levee - would need some separation from levee; little to no green space other than trail on levee top; creen is not really an amenity; would require all properties to be purchased by city alone; publically not a good option	public wont buy in	USACE alignment with all levee and Merriam Drive on alignment with levee; trail on top of levee
4	no	similar to FS but all levee; less cost levees instead of floodwalls; more takings than FS; more limited amount of riverside amenities could be added	no change to city plans - no green space or creek amenity; many sanitary conflicts like FS; loose old downtown		
5	no	similar to 6; less setback might still need higher levees/fw;	currently no impacts to the bus property; bumpin feature not very good benefit hydraulically		keeps existing merriam drive
6	yes consider bus property acquisition as a last resort for additional conveyance and detention	keeps old downtown; lower levee b/c setback; farmers market next to amphitheater; opens up floodplain; less costly levees vs floodwalls; meandering levee is more visually appealing; includes detention	more property acquisition of bus property - big impacts to that property;	bus company may have some sway with city council and likely if cut off access we will be into buying their whole property	raises current Merriam Drive, bridge lengthening; could include benching as needed
7a	yes	no floodprotection required - other than short floodwall DS of johnson drive (benching only); farmers market next to amphitheater; no detention needed; more natural visually; creek as amentiy; much of the development and road project is separate from flood risk reduction project	does not preserved old downtown; lower access to SS gets overtopped with water more frequently (water tight bolt down lids)	channel widening can result in sedimentation issues - could impact how the benching is done; could result in maintenance issues; big events drop out the sediment; would have to clear SS pipes	4-5 ft vertically from channel bottom to first bench; bench approximately 80ft to get conveyance then slope to existing ground; similar to 1b, but 1b has levees too
7b	yes	attempts to preserve market area where it is	ped bridge relocation or removal required		add west side of creek widening to 7a or really to any/all alternatives

CHARRETTE NOTES

Notable conclusions and comments from the Charrette:

- ❑ BRIDGES AND ROADS
  - Merriam Drive Realignment (see city corridor plan) may not be required if it is not needed to improve the alignment of the bridge at the Turkey Creek Crossing.
    - City currently has Johnson County CARS (County Assistance Road System) funding for Merriam Drive improvements along the current alignment.
  - Realigning the Merriam Drive bridge is not required for flood protection project.
    - Realigning would allow the bridge to be constructed without closing the existing bridge/road.
    - Realigning would shorten the bridge required to provide a larger creek opening, compared to keeping it on alignment, but additional real estate and roadway re-alignment may not be more cost effective in the end.
  - Replacing the Merriam Drive bridge with a longer bridge (more conveyance) will likely be required regardless because the 3-4ft parapet from the feasibility study is not a valid solution – currently sized at 6ft due to current hydraulic profile results in unstable bridge. Raising the bridge could also provide more conveyance, but could impact more properties.
  - Merriam Drive (regardless of alignment) will be considered the backbone of future development
  - Pedestrian bridge at Farmers Market is acknowledged as likely going to need to be removed as a result of benching in the area and could potentially be relocated with a city contract to another crossing location.
  - ADT on 55th St is 7-8000 vpd and on Johnson Drive 4-5000 vpd
  - Levee/Road – where the levee section is adjacent to the roadway would want separation – include a 15ft “buffer” between the levee toe and the roadway public right of way.

CHARRETTE NOTES - CONTINUED

Notable conclusions and comments from the Charrette:

- ❑ PROPERTIES
  - The marketplace can stay where it is or it can be relocated to another location – iconic area for Merriam. If it stays and is in flood plain, the city will need to include some warning system for the area in the event of a flood. Reconstructing in new location would be a city project and removal would be a levee project cost.
  - Bus property could be widened to increase flow capacity downstream – it would be a large and likely costly property to acquire since it is on both sides of the creek (functionally used together). If impacts to the bus property access are too great and have to acquire the property anyhow, it would be good to include for conveyance and/or detention.
  - There are no properties downtown that are on the historical register.
  - Need to consider trying to keep the old downtown area (between Johnson Drive and Hocker Drive on the West side of Merriam Drive) even though not a top priority for the city, in order to address question what is the impact project if we were to preserve that area. What are the consequences – Johnson Drive Bridge replacement, etc?
- ❑ UTILITY RELOCATIONS
  - If a utility is required to be relocated as part of the levee project and within their own easement, relocation costs are levee project costs and can be considered reimbursable LEERD (Land, Easements, Rights-Of-Way, Relocation, and Disposal Areas).

CHARRETTE NOTES - CONTINUED

Notable conclusions and comments from the Charrette:

- ❑ SANITARY SEWER
  - Most of the Sanitary Sewer in the downtown reach is 42” diameter and mostly in existing easement
  - Current estimates by JCW is a cost of $8-10M to relocate for the whole USACE project
  - Cover and clearance criteria/requirements is available on their website.
  - Current plans for upsizing elsewhere (large storage facility upstream of here), but if replacing/relocating required for this project they could include some upsizing of pipes instead or in addition to current plans.
- ❑ MISC
  - Merriam Drainage District expressed need for access to maintain limestone block wall and reminded the team of the constraint of not being able to traverse over sanitary sewer lines that cross in the creek bottom.
    - Merriam Drainage District acknowledges long term degradation of limestone block walls and material flowing through Upper Turkey Creek.
  - Feasibility study – 2g – which included Atlas 14 rainfall considerations – had a B/C of 1.8 vs B/C ratio of 2.0 for 2d (NED plan). See table 5-15 (page 5-36) in the feasibility study report.
  - City and County acknowledged that the decision to proceed with 2d was partially on the assumption that FEMA would not adopt the Atlas 14 updates (per FEMA/city meeting). Criteria to select recommended plan was based on net benefits, not on the ability for areas to be taken out of the floodplain.
  - Recreation improvements, such as trails – other than gravel trail and seeded grass – would be city funded (separate project or betterment to USACE project).
  - Impacts to local activities (ie at Marketplace) would be substantial during construction, but other options are available to accommodate – relocate and/or cancel.

CHARRETTE NOTES - CONTINUED

Notable conclusions and comments from the Charrette:

- ❑ MISC - Continued
  - Updated hydrology methodology will be incorporated in the hydraulic evaluation of the alternative (Johnson County currently working on the update and will provide near end of September)
  - Early City concepts show a water feature near the north end of the market place. During normal water levels, the water feature would be more of a dry detention area rather than a pond like effect. To hold water during normal water levels, a grade control structure would be required to back the water up in the creek enough to pond near the marketplace. Due to the relatively steep slope of the creek, the grade control structure would need to be several feet tall. Additionally, during high water the grade control structure would most likely need to be removed to maintain the capacity needed for the levee/floodwall system to handle the 1% AEP. Due to the flashiness of the creek, it would be difficult to temporarily remove this grade control structure in time without endangering personnel. During discussions, it was concluded this area is not conducive for a water feature like this to be implemented.

2024 CONCEPT MODELING RESULTS

CHARRETTE ALTERNATIVES 3-6

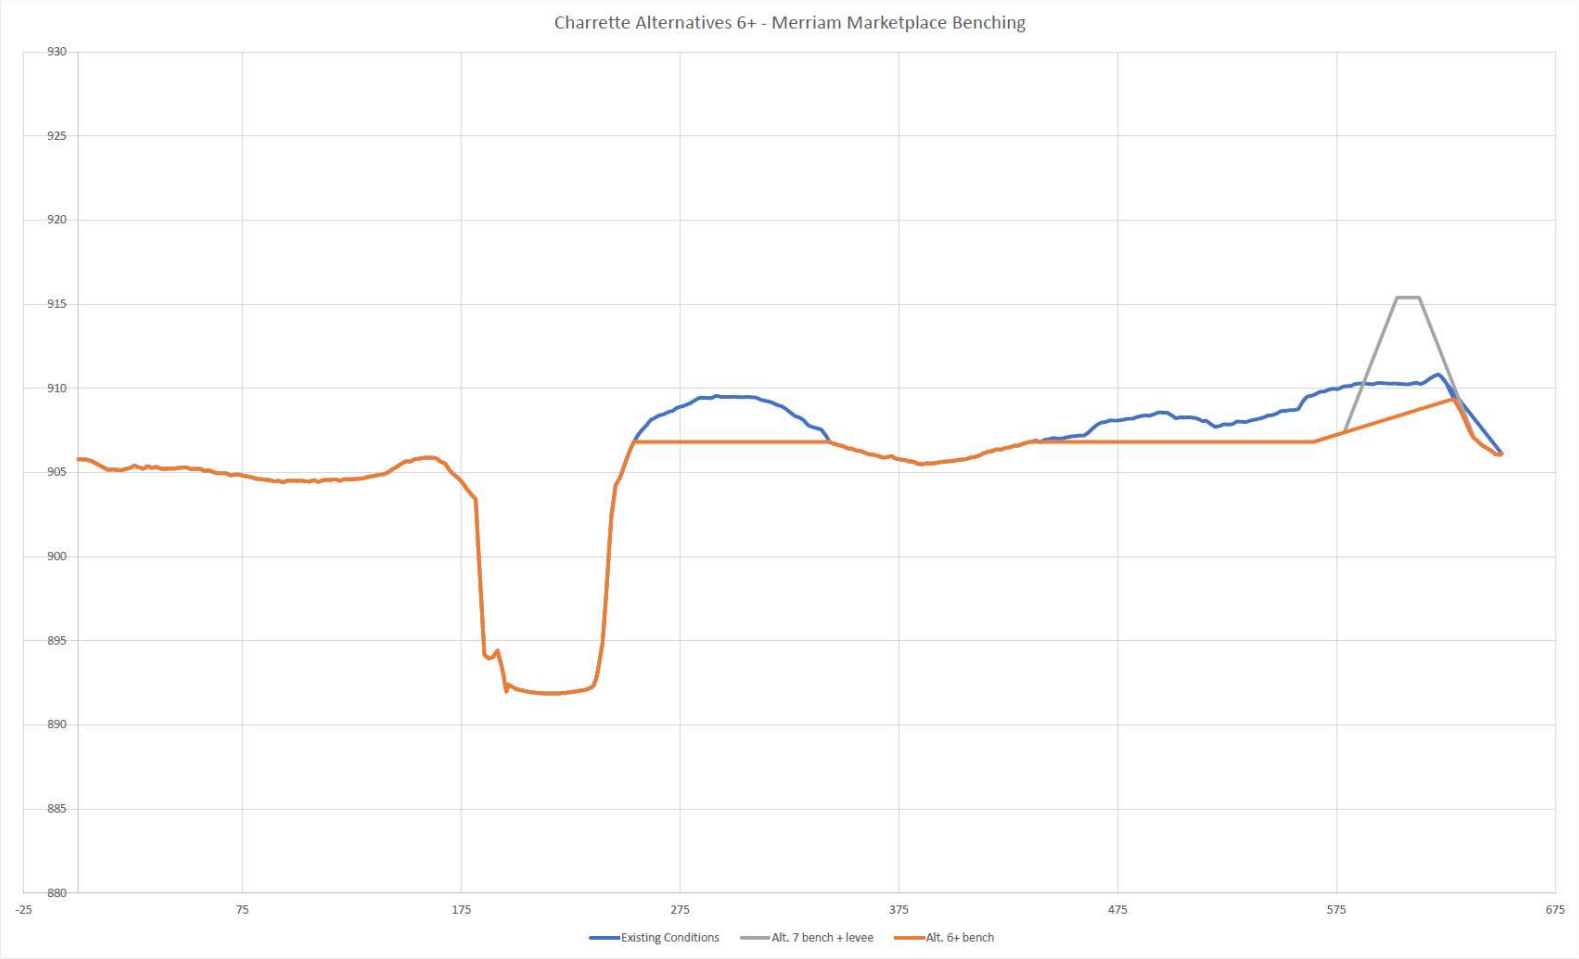
#3
Alternative 7a & 7b (including benching around market area) + preserve old downtown

#4
#3 + increase length of Merriam Drive bridge on current alignment

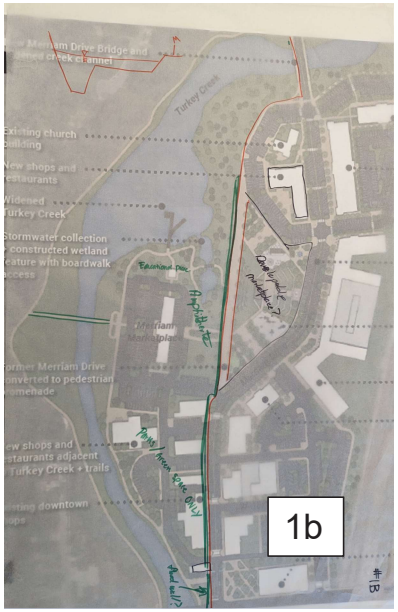
#5
#4 + remove market area and bench more

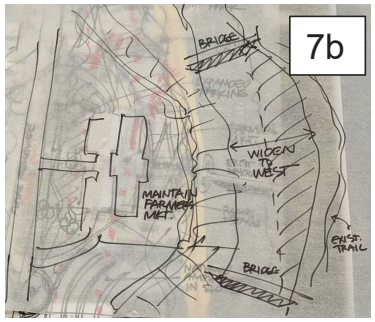
#6
#5 + take out old downtown for conveyance and floodwall transition from Johnson Dr.

CHARRETTE ALTERNATIVE BENCHING



CHARRETTE ALTERNATIVES 7 & 8



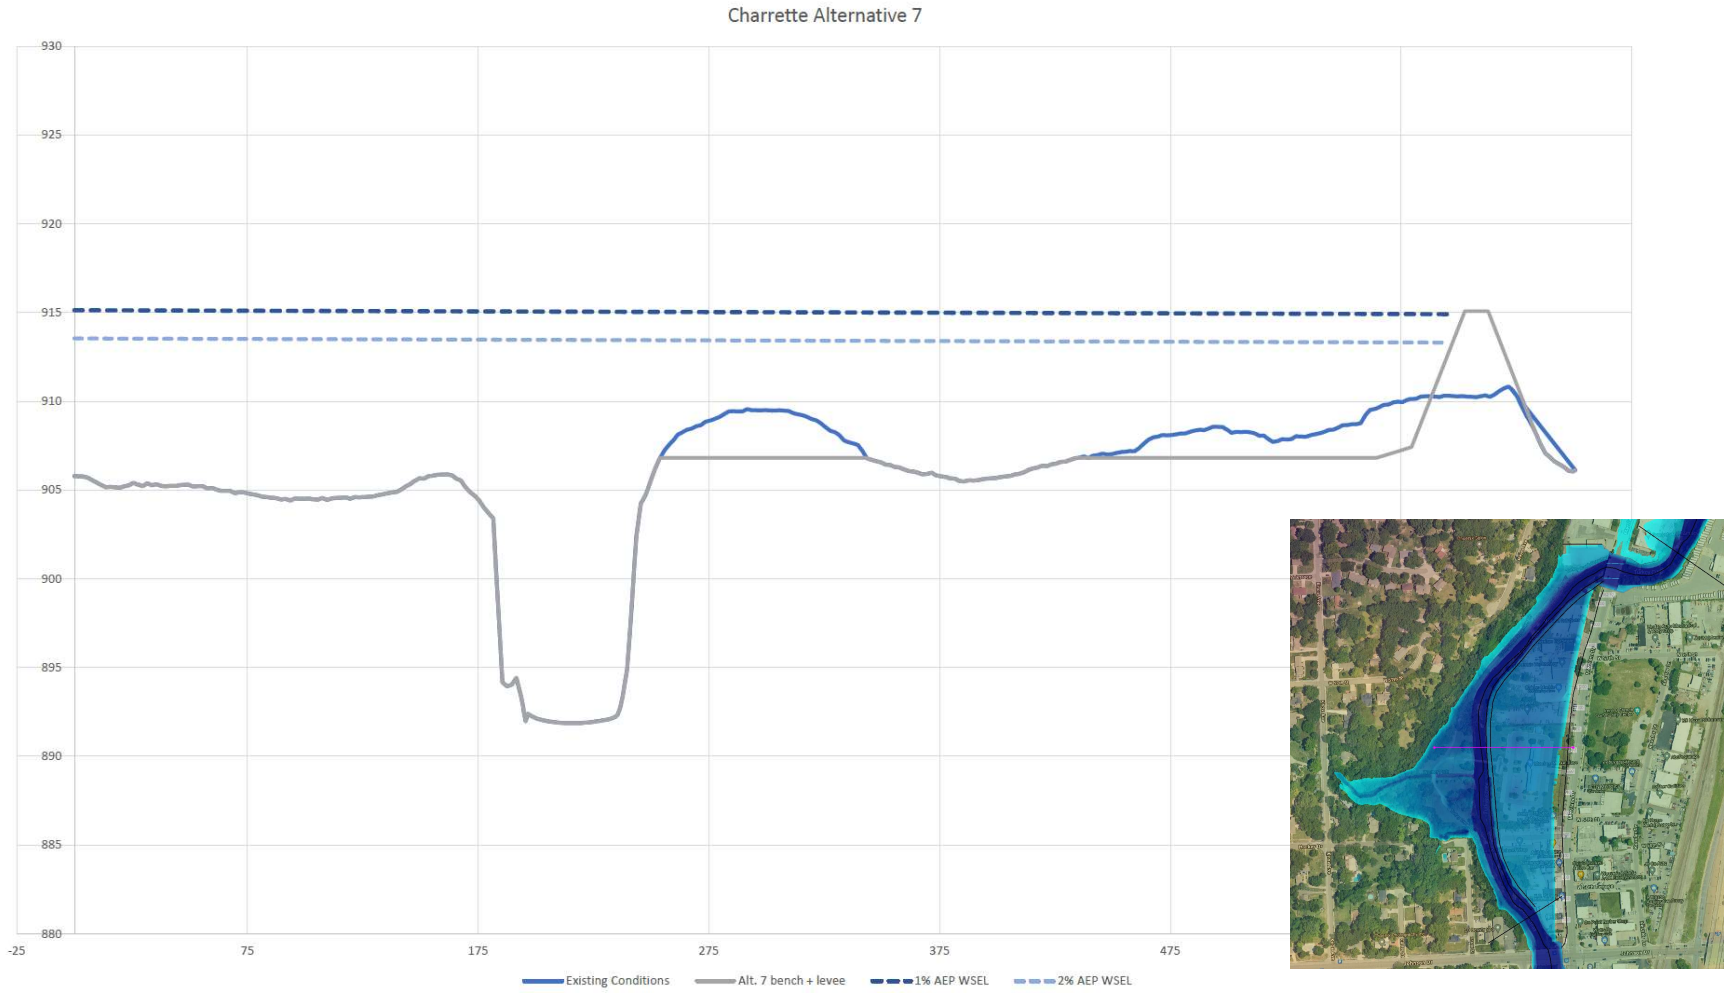


#7
#6 + add up to 2-3feet of levee as needed (see Alternative 1b)

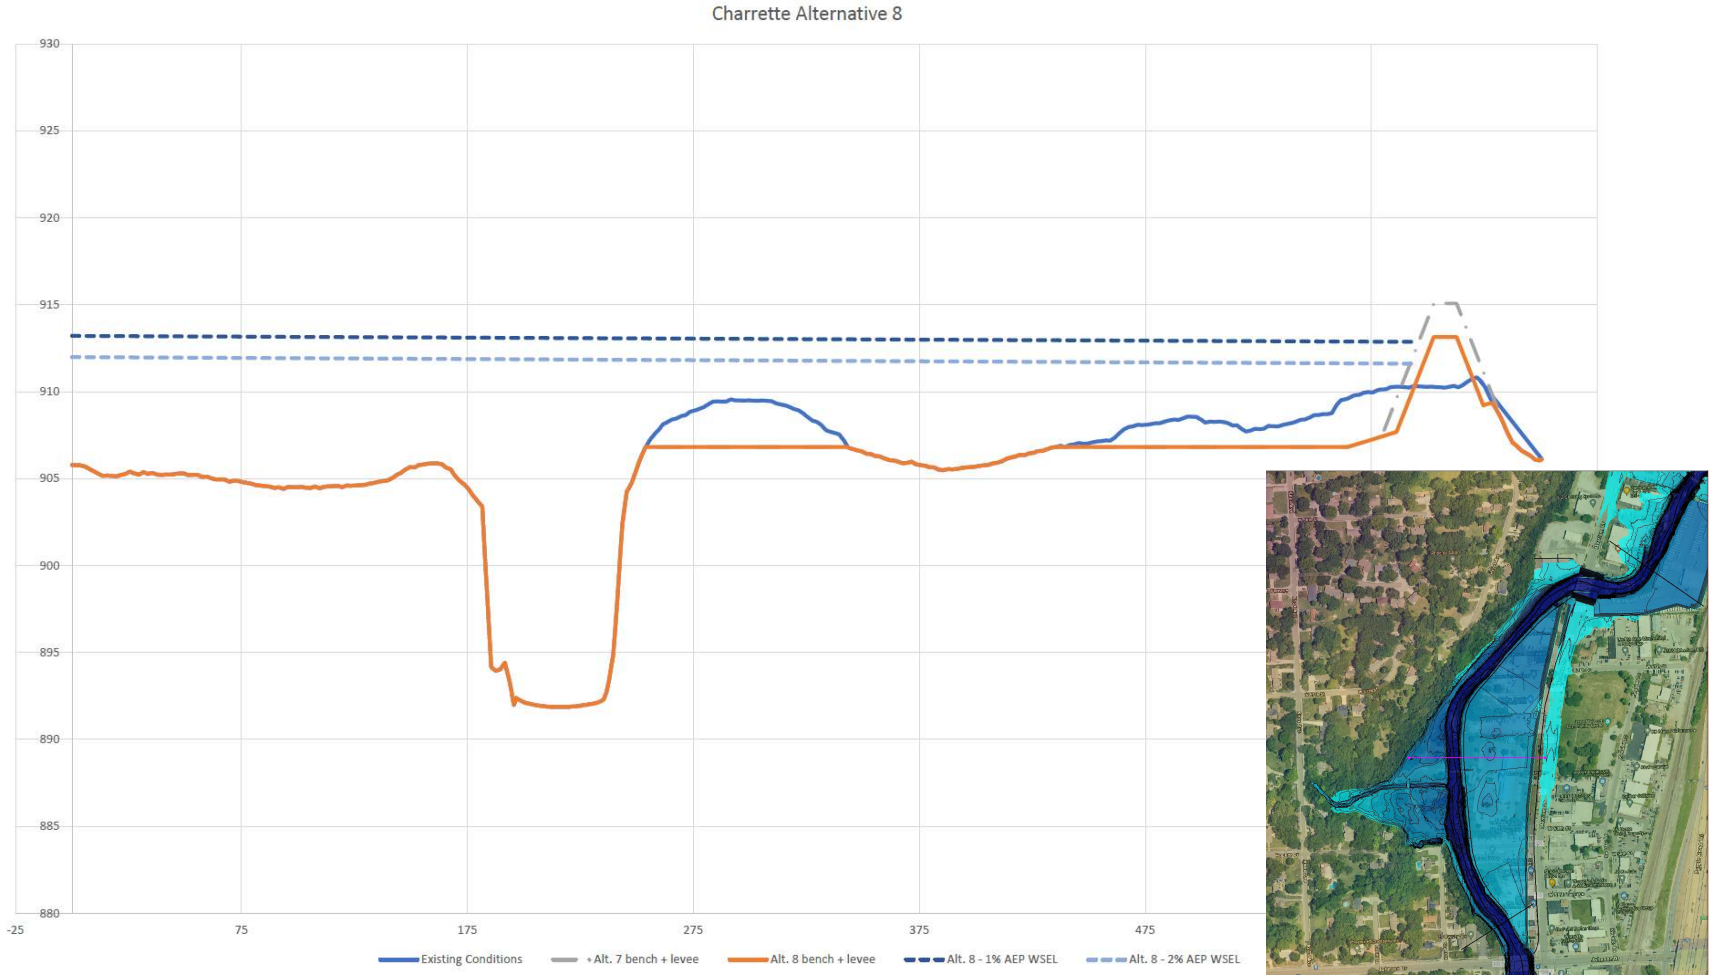
#8
#6 + bus property channel widening and remove bus private bridge

MERRIAM
just right.

CHARRETTE ALTERNATIVE – ALTERNATIVE 7



CHARRETTE ALTERNATIVE – ALTERNATIVE 8



CHARRETTE ALTERNATIVE 8 ADD'L BENCHING

APPENDIX L – ENGINEERING CONSIDERATIONS AND INSTRUCTIONSP FOR FIELD PERSONNEL (ECIFP)

This page was intentionally left blank for duplex printing.

L ENGINEERING CONSIDERATIONS AND INSTRUCTIONS FOR FIELD PERSONNEL (ECIFP)

Project Name: Upper Turkey Creek FRM

Project Location: Merriam, Kansas

P2 Number: 505229

L.0 VERSION HISTORY

Version No.	Version Date	Description of Change
0.0	11/26/2024	Original Version
1.0	03/242026	65% Design Update

L.1 PURPOSE

L.1.1 Purpose

This Engineering Considerations and Instructions to Field Personnel (ECIFP) report expands on the construction specifications and drawings in areas where added information, not considered essential to the Contractor, is considered helpful to construction personnel administering the contract. This information helps ensure that project features are constructed in accordance with design assumptions, constraints, and overall intent.

The ECIFP points out critical construction issues and concerns and highlights specific items that may need additional clarification. This document does not modify and should not conflict with contract plans and specifications. The Design Analysis (DA) is also available to the field team and documents the logic and calculations relevant to design decisions. Neither the DA nor the ECIFP are part of the contract.

This document establishes a baseline for communication and coordination between the design and construction personnel; not every issue is addressed in this document. Feedback and open communication between designers and field personnel, prior to and during construction, are encouraged.

L.1.2 Key Contacts

John Westbrook	Structural Engineer	816-389-3249	john.w.westbrook
Derek Jenson	Geotechnical Engineer	816-389-2323	derek.h.jenson

L.2 GENERAL PROJECT INFORMATION

L.2.1 Project Description

a. Refer to DDR Part 01 for Project Narrative.

L.2.2 Work Restrictions

a. The creek is very flashy, so there isn't much advanced warning available. The Contractor will need to park their equipment overnight above the existing bank elevation. We will account for the creek coming up as weather days and not plan to issue stop work.

b. Some of the construction will require a lane to be closed along various roads including Mastin St near Shawnee Mission Pkwy, Merriam Dr just south of Johnson Dr, and Merriam Lane just south of Johnson Dr. Per a meeting with the City October 2024 they prefer for lane closures to not impact traffic as much as possible. This means that both directions should be able to still pass, and the duration of that closure should be kept to a minimum.

c. Utility relocations will be completed by third-party owners but will require coordination with the Contractor during Construction.

d. There will be two roadway bridges replaced as part of this project.

- Details of the traffic control will be worked through with the City of Merriam with potential input from the City of Shawnee. Through traffic from the west that would use Johnson Drive to reach I-35 entrance ramps would be detoured at the intersection of Johnson Drive and Nieman Road southbound on Nieman Road to Shawnee Mission Parkway, then eastbound to the entrance ramps of I-35 at Shawnee Mission Parkway. Destinations along Johnson drive east of the intersection of Nieman Road and the Bridge can still be accessed by setting up barricades for the road closure approximately 100 feet to the east of the intersection of Grant Street and Johnson Drive and using that intersection as a turn around point and construction entrance for the construction group.
- For the bridge construction at Merriam drive traffic could be diverted to the north to west 55th Street and to the south could be diverted to Johnson Drive. The two bridges would not be able to be done at the same time. The diverted traffic from south of the Merriam drive bridge would be able to then use Knox Ave to the west, but would need access via Johnson Drive Bridge.

e. There are several businesses impacted by floodwall/levee construction along the back of their property. Some of these impacts could negatively affect their business. It's important that the Contractor limit the impact per property owner. Specifically, floodwall constructed at the bus barn on the downstream end of the project should be limited to the school's summer break.

f. Care should be taken to not disturb the existing limestone block wall unless called out to remove in the plans. This wall is not stable enough to handle tracking of construction equipment.

g. RB floodwall south of Johnson Drive will start at the newly constructed bridge and head south. Due to limited space, the Contractor may not be able to pour the floodwall in alternating monoliths where space is limited, especially adjacent to the existing buildings. They may need to pour one base, wait the required 7 days, and then pour the next base immediately adjacent. This is possible but will drastically slow production. The Contractor is allowed to over excavate for a working pad, but should avoid excavating the stacked limestone block wall. If they over excavate, they may need to place more riprap than what is shown in the Drawings.

L.2.3 Project Schedule / Phasing

The current plan is to have two contracts. One for Merriam and Johnson Drive bridge, and one for the remaining levee and floodwall construction. The bridge contract will need to be complete prior to starting the levee and floodwall contract. It's estimated that each bridge will take one year to complete. They cannot be constructed at the same time since this would severely impact traffic in Merriam. One bridge at a time is allowed to be taken completely out of service to construct the new bridge. The bridge contract will total roughly two years. The levee and floodwall contract is estimated to take roughly three years to complete.

L.2.3.1 Conceptual Construction Phasing

a. Merriam Drive Bridge

1. Close the road and detour traffic. Maintain access to the few businesses adjacent to the bridge.
2. Coordinate utility relocations that could not be relocated before construction.
3. Demolish the bridge
4. Construct new bridge
5. Construct intersection/road tie ins

b. Johnson Drive Bridge

1. Close Johnson Drive from Campbell Lane to Merriam Drive and detour traffic. Keep east intersection open.
2. Coordinate utility relocations that could not be relocated before construction.
3. Demolish the bridge
4. Construct new bridge
5. Close Johnson Drive/Merriam Drive intersection. Construct intersection and Johnson Drive tie-in
6. Construct Merriam Drive tie in north of the intersection.
7. Construct Merriam Drive tie in south of the intersection.

c. Levee and Floodwall Construction Contract

1. It's assumed the Contractor will divide the levees and floodwalls into left bank, right bank from Shawnee Mission Pkwy to Johnson Drive, and right bank at downtown Merriam.
2. Demolish buildings within construction limits
3. Demolish other features within construction limits
4. Coordinate utility relocations
5. Construct storm features
6. Excavate detention basin and use any suitable material to construct the levee through this reach. Conceptual quantities suggest there should be enough suitable material to construct the levee. During drilling, petroleum was discovered. Care should be taken to dispose of any contaminated soil.
7. Construct levee and access ramps
8. Construct floodwalls. It's assumed the Contractor will start at the newly constructed bridges and work their way out from there.
9. Final cleanup and seeding

L.2.4 Haul Routes/Staging Areas

a. Haul routes for Construction will be limited to public roads. There are some private roads within the project limits that should not be used for haul routes. See Drawings haul routes.

b. Staging areas will be limited to land owned by the City of Merriam, Merriam Drainage District, or properties to be acquired as part of the project. The Contractor can elect to acquire additional temporary easement agreements with the property owners if they wish.

L.2.5 Advanced Modeling Requirements

a. Refer to Part 17 – References, paragraph 17.4 Computer Programs.

L.3 DISCIPLINE SPECIFIC INFORMATION

L.3.1 Environmental

a. Hazardous, Toxic, and Radiological Waste

A boring (ADU-201A) encountered petroleum contamination 10-ft bgs north of the parking lot on at 5920 Merriam Dr. A floodwall is proposed 40-ft was of this location. If petroleum contaminated soil is encountered during installation of the floodwall it will need to be disposed off-site at a permitted facility.

Another boring (ADU-212) encountered buried debris 5-ft bgs at 5726 Merriam Dr. A detention pond and levee is proposed at this location so there may be a large volume of debris encountered that requires disposal at off-site at a permitted facility.

A GPR survey identified a number of subsurface anomalies. The nature of the anomalies is unknown. Properties where the anomalies were encounter are listed below:

- 5568 Merriam Dr
- 5643 Merriam Dr
- 5726 Merriam Dr
- 9420 W 61st St
- 9420 W 61st St
- 80 feet west of the intersection of W 61st St and Merriam Ln

The location of these anomalies can be found in Appendix F – Environmental.

It is possible during construction of the flood control features that currently unknown contamination or debris will be encountered. The specifications should require the Contractor to prepare a Contingency Plan outlining actions they will take if contamination soil or debris are encountered.

L.3.2 Geotechnical

a. Levee Inspection Trenches

The levee segments of the system will have inspection trenches to verify satisfactory foundation soils. An inspection trench will be excavated along levee centerline for all levee reaches. For levees 6 feet or higher, the trench will be 6 feet deep. For shorter levees, the depth of the trench will be equal to the levee height. The trench width should be approximately 6 feet to allow for compaction equipment.

The inspection trench will allow for detection of any continuous pervious zones, voids, or unacceptable fill material. The trench will be backfilled with the excavated material compacted in lifts. If unacceptable material is encountered, it will be replaced with impervious fill to ensure there are no continuous seepage paths.

The construction QA representative should observe all inspection trenches and communicate any issues with the project geotechnical engineer. The geotechnical engineer should be present with the QA representative for the first inspection trench and make regular weekly visits to check progress thereafter.

b. Floodwall Foundations

The construction QA representative should observe footing excavations for T-walls and should observe installation of sheet piles for I-walls, with the geotechnical engineer making regular weekly visits during foundation preparation.

L.3.3 Civil

a. There is an existing trail system running along and within the project limits. There will need to be some additional signage for the public during Construction. The Sponsor will determine trail detour routes, if required. Staging areas adjacent to existing trails may require additional security measures as equipment and potentially hazardous work areas could be visible to the public.

L.3.4 Structural

a. Gatewells & Manholes

There is an existing limestone block wall within the creek. Portions of it will need to be removed to outlet storm drainage during Construction. See the plans for details.

b. Enlarging the key of the floodwalls for ease of construction for contractor

During conversations with team members of the Construction Division it was learned that in past projects the contracts have requested to make an extra thick key to ease construction efforts and to gain efficiencies. The additional materials

required to make the keys much thicker than the design thickness were offset by the gained efficiencies. During the design preliminary CT Wall runs were made for the 10 foot tall wall profile. These preliminary runs did not meet the required minimums for factors of safety for sliding failure. If the request is made by the contractor to use an alternate profile for the wall's foundation to ease in the construction, the structural engineer should be engaged early in that process to determine if the key that is being suggested by the contractor will sufficiently resist sliding and overturning.

L.3.5 Hydrology & Hydraulics

a. Woody vegetation, including trees and shrubs, will need to be cleared within 15-feet of the levee and floodwall toe for both the riverside and landside.

b. As mentioned above, Turkey Creek watershed is very flashy with no automatic flood stage forecasting. 2-3 inches of rainfall within an hour could result in isolated areas of out of bank flooding. Monitoring rainfall forecasts is recommended.

L.4 UTILITY / PERMIT INFORMATION

All utility relocation coordination is the responsibility of the non-Federal Sponsor. Utility coordination will begin after USACE issues the RE NTP. USACE personnel will provide technical support during utility relocation coordination.

L.5 RECOMMENDED SITE VISITS BY DESIGN PERSONNEL

Will be completed after 50%.

Research Report

Rainfall for Flood Studies: Indian and Tomahawk Creeks

Prepared for
Stormwater Management Program
Johnson County Public Works

By
Bruce McEnroe, PhD, PE
Bruce McEnroe Consulting LLC

November 30, 2023

1. Background and Objectives

Johnson County is currently working to update its floodplain maps using HEC-RAS 2D modeling technology. The updated 2D models for the Indian Creek and Tomahawk Creek watersheds have been developed but not yet finalized. One remaining issue is selection of rainfall inputs for estimation of flood levels with specified recurrence intervals. This report provides findings and recommendations from research on that issue. The main concerns are the storm duration, the temporal distribution of rainfall within the storm, and the possible application of areal reduction factors to point rainfall for watersheds over a certain size.

The Federal Emergency Management Agency (FEMA) provides some basic guidance for rainfall inputs to flood models in the *Hydrology: Rainfall-Runoff Analysis* (2019) volume of its *Guidance for Flood Risk Analysis and Mapping* document series. FEMA's guidance includes the following statements:

- "For most applications reflected on FIRMs, the spatial distribution of rainfall is taken to be constant."
- "Temporal storm distributions must be chosen to reflect the local climatic conditions."
- "The choice of temporal storm distribution must be fully documented. If the source of the distribution is not a federal, state, or regional agency, the documentation must include a detailed description of the derivation of the distribution, including sources of data and the means of fitting those data to a particular distribution."
- "The storm duration chosen must exceed the time necessary for runoff everywhere in the basin to reach the outlet, also known as the time of concentration."
- "The Mapping Partner must document the use of areal reduction factors (or lack thereof)."

This report addresses all of these points and provides fully documented recommendations for the Indian and Tomahawk Creek flood models with potential application to other Johnson County flood models.

2. Gage Records and Flood Frequency

Indian Creek is a major stream in the suburban area of east-central Johnson County. At the Kansas-Missouri state line (the eastern boundary of Johnson County), its drainage area is 64.2 mi^2. Tomahawk Creek is a right-bank tributary of Indian Creek. Tomahawk Creek joins Indian Creek 0.8 miles west of the state line, at which point its drainage area is 23.3 mi^2.

The U.S. Geological Survey (USGS) currently maintains two streamflow gages on Indian Creek and one gage on Tomahawk Creek. Station 6893300, Indian Creek at Overland Park, is located on the downstream side of the bridge at Marty Street, where the drainage area is 26.6 mi^2. From March 1963 until May 1977, the gage was located 700 feet downstream at 103rd Street. Peak-flow records are available from water year 1964 to present, and continuous stage and discharge records date from 1989. Station 6893390, Indian Creek at State Line Road, is located on the downstream side of the bridge at that location. Continuous stage and discharge records at State Line Road date from March 2003. Station 6893350, Tomahawk Creek near Overland Park, is located on the downstream side of the bridge at Roe Avenue. The drainage area at that location is 20.5 mi^2. Continuous stage and discharge records at the Tomahawk Creek gage date from July 2011. Because USGS stage and discharge data are recorded and reported at 15-minute intervals, those data can slightly understate the actual flood peaks.

Johnson County's extensive network of ALERT flash-flood warning system includes 28 rainfall gages and 22 water-level gages in the Indian and Tomahawk Creek watersheds. Many other gages surround the two watersheds. The ALERT gage records provide high-resolution data that are useful for flood model calibration.

The USGS gage on Indian Creek at Marty Street is the only discharge gage in the two watersheds with a record of sufficient length for a meaningful statistical analysis. The record includes 59 years of peak-flow data (1964-2022). Figure 1 shows the results of a flood-frequency analysis for the entire peak-flow record by the Bulletin 17C methodology, using the station skew rather than a weighted skew. This analysis yields a 1%-annual-chance discharge of 13,560 cfs and a recurrence interval of 134 years for the 8/22/2017 flood of record. However, six of the seven highest annual peaks lie above the fitted curve, which suggests that the frequency analysis might overstate the recurrence intervals of the largest floods.

In the USGS dataset of annual peak flows for station 6893300, the values from 1980 to present are flagged as significantly impacted by urbanization. The Indian Creek watershed upstream of the Marty Street gage did undergo substantial urbanization during the first two-thirds of the period of record, with hydrologic impacts increasing gradually over time. For present purposes, the current hydrologic regime can be considered to start in 1977, when the USGS gage was relocated to the new Marty Street bridge. Figure 2 shows the results of a Bulletin 17C flood-frequency analysis for the 46-year period 1977-2022. This analysis yields a 1%-annual-chance discharge of 15,020 cfs and a recurrence interval of 80 years for the flood of record on 8/22/2017. Table 1 compares the flood-frequency estimates from the analyses of the 1964-2022 and 1977-2022 annual peaks. The estimates derived from the 1977-2022 data probably better reflect current conditions because the Indian Creek watershed upstream of Marty Street was much less developed prior to 1977 than at present.

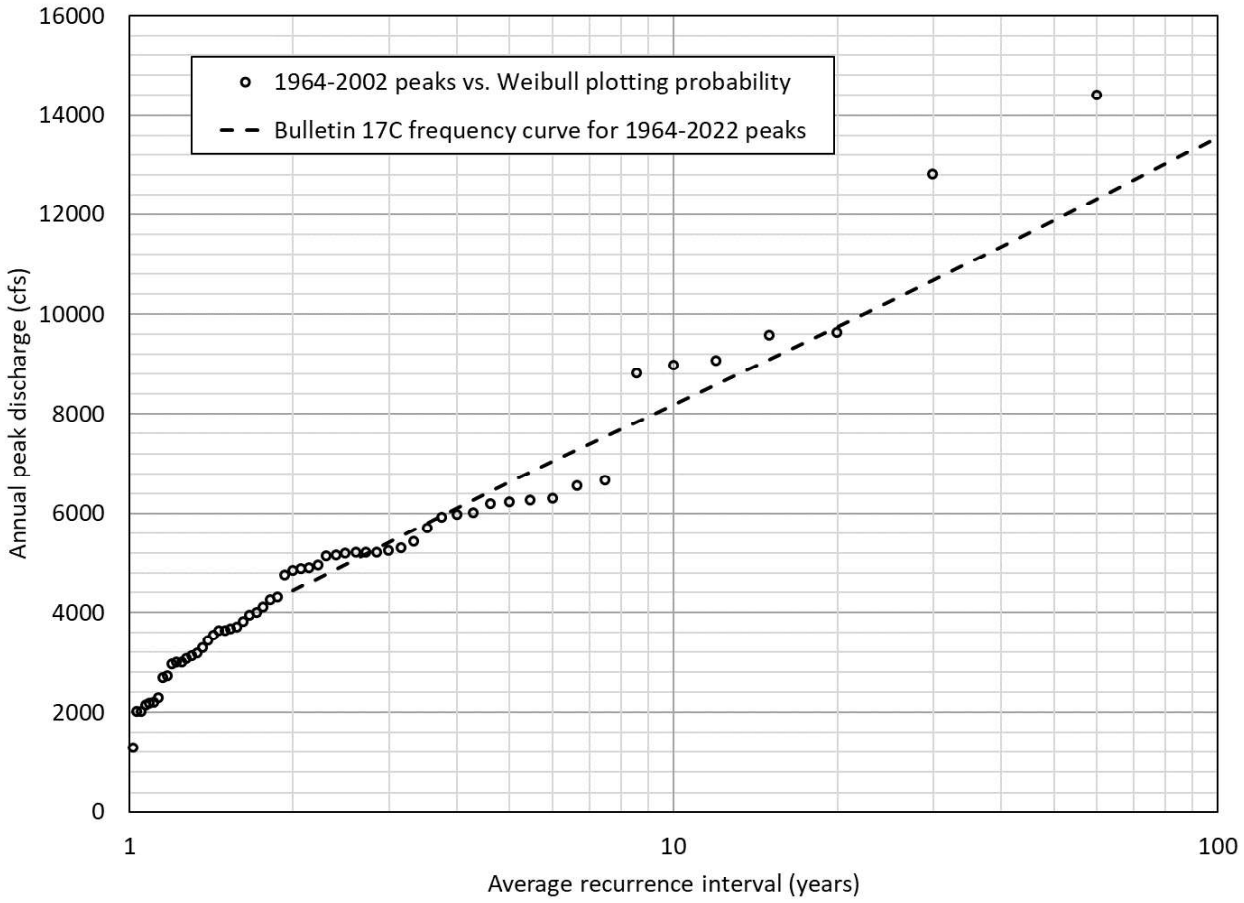

Figure 1. Discharge-frequency relationship for USGS station 6893300, Indian Creek at Overland Park (Marty Street), for period 1964-2022

.

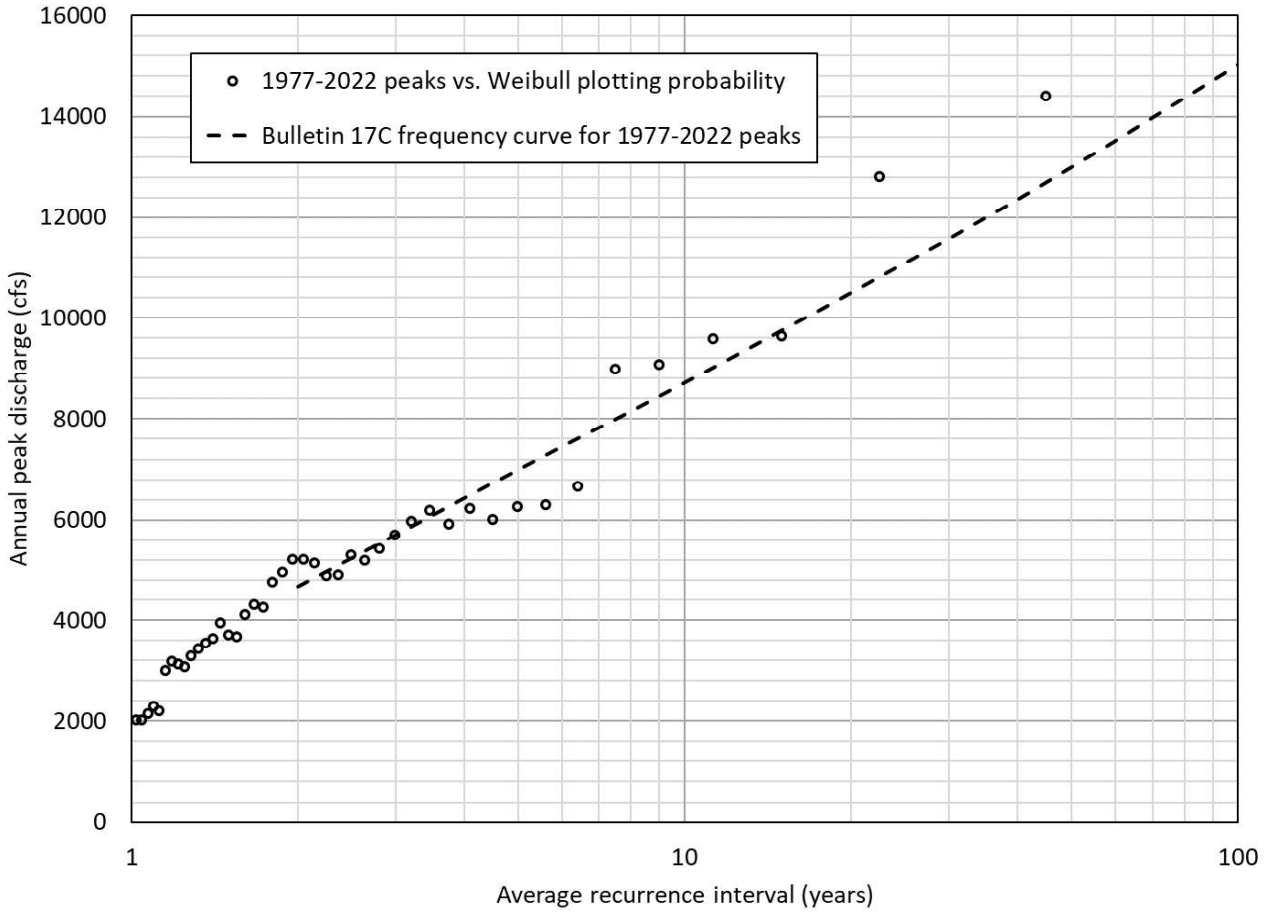

Figure 2. Discharge-frequency relationship for USGS station 6893300, Indian Creek at Overland Park (Marty Street), for period 1977-2022

Table 1. Discharge Frequency Estimates for Indian Creek at Marty Street

Annual exceedance probability	Discharge (cfs)	
	Period 1964-2022	Period 1977-2022
50%	4440	4469
20%	6631	6994
10%	8188	8711
5%	10260	11080
2%	11880	12990
1%	13560	15020

The quantity measured directly at USGS stream-gaging stations is not discharge but rather stage, defined as water-surface elevation above a fixed datum. A previously established rating curve/table (discharge-stage relationship) is used to estimate the discharge from the measured stage. The USGS makes field measurements of discharge by current-meter survey periodically, typically several times a year, at each station and uses those measurements to verify or adjust the rating curve.

Figure 3 shows the USGS's current rating curve for the gage on Indian Creek at Marty Street, with field measurements and major flood peaks superimposed. Most of the discharges measured in the field were under 100 cfs; only a few were much higher. The highest discharge measured directly was 4190 cfs on 3/04/2004. The stage-discharge data from the field measurements, particularly those from 2001 to present, plot in a fairly tight curve. The relationship does not appear to have shifted significantly over time. At flows above 4190 cfs, the rating curve has no hydraulic basis. It is simply an extrapolation of the equation shown on the graph, which was fitted to the field measurements for flows from 600 cfs to 4190 cfs. Discharge estimates for flood peaks with water-surface elevations above 869 feet (gage readings above 12 feet) may be somewhat in error due to the uncertainty of the rating curve. However, the reported water-surface elevations for those events are reliable.

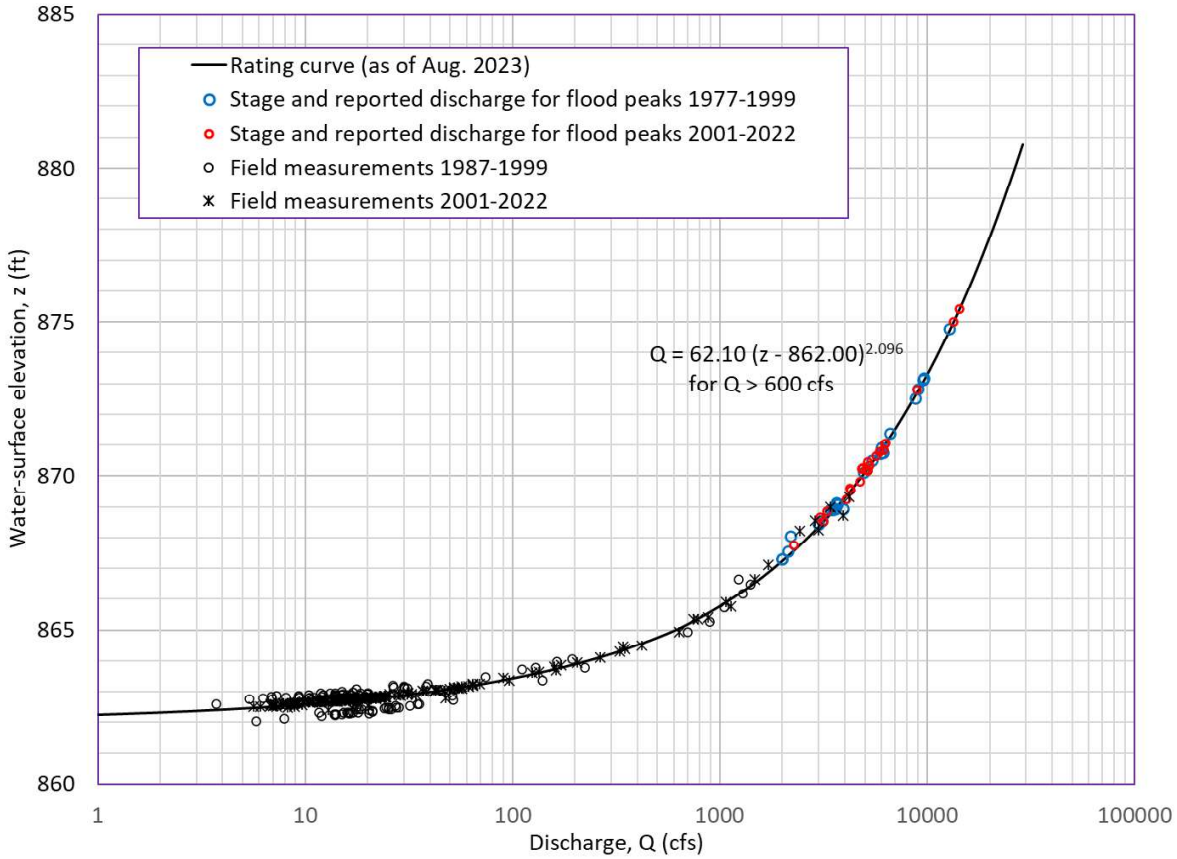

Figure 3. Rating curve for USGS station 6893300, Indian Creek at Overland Park (Marty Street)

Figure 4 shows the flood frequency relationship in Figure 2 re-plotted with discharges replaced by the corresponding water-surface elevations from the USGS rating curve. The 1%-chance discharge of 15,020 cfs corresponds to a 1%-chance stage of 875.70 feet.

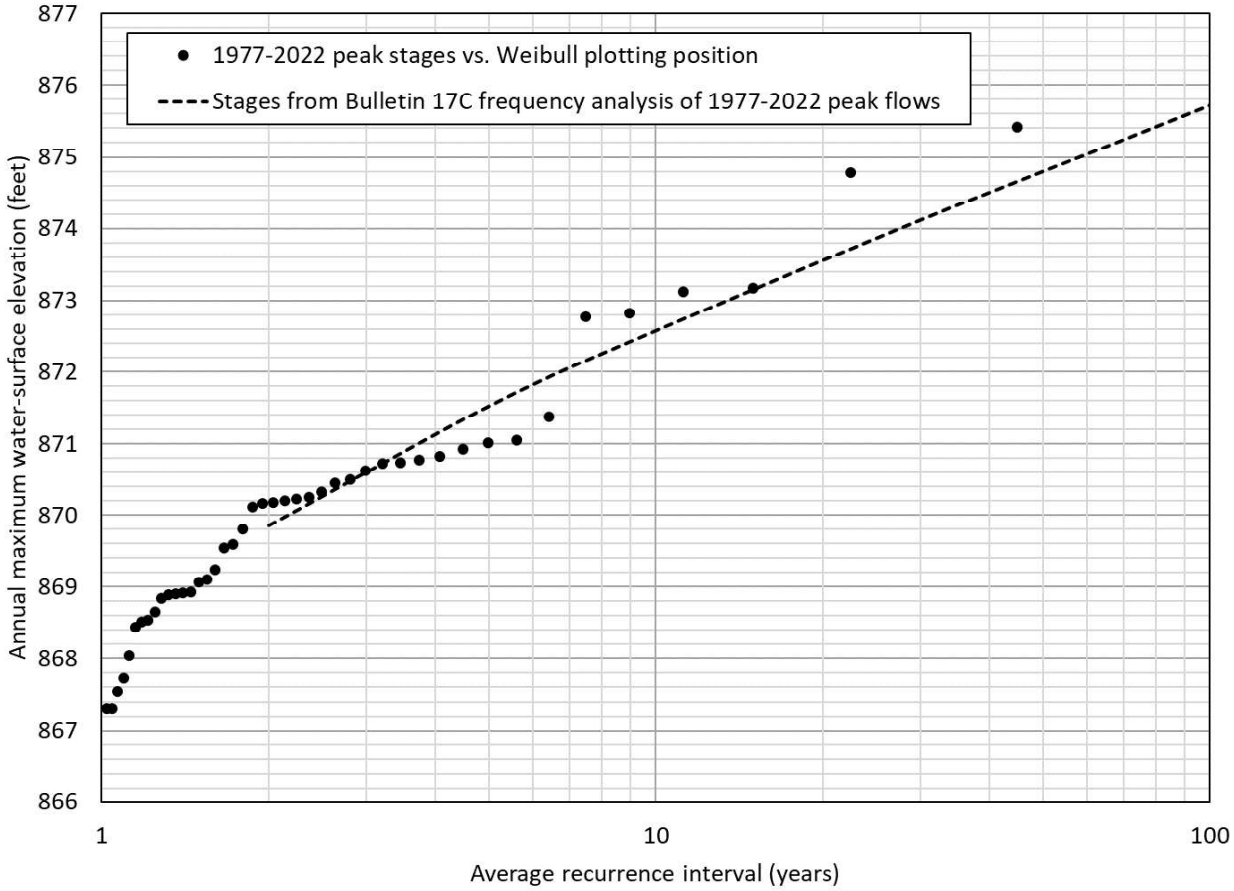

Figure 4. Stage-frequency relationship for USGS station 6893300, Indian Creek at Overland Park (Marty Street), for period 1977-2022

The flood of record on Indian Creek at Marty Street occurred on August 22, 2017. USGS records show a peak stage of 875.41 feet and a corresponding peak discharge of 14,400 cfs. ALERT gage IN09 at the same location recorded a peak stage of 875.66 feet. The discrepancy is probably due to the difference in the frequency of the measurements. USGS gages report stages at 15-minute intervals, while ALERT gages report much more frequently when conditions are changing rapidly.

3. Historic Storms and High Flows on Indian and Tomahawk Creeks

This examination of historic storms in the Indian and Tomahawk Creek watersheds focuses on gaged events that produced flows with estimated recurrence intervals of 2 years or greater. The figures in Appendix A show plots of rainfall intensities at 5-minute intervals at the Marty Street ALERT gage superimposed on USGS discharge hydrographs at the Marty Street and State Line gages for eighteen such events. Appendix B provides similar plots for three substantial floods at the Tomahawk Creek gage. The events in each appendix are ordered from highest to lowest peak flow. The hyetographs and hydrographs are plotted with identical discharge and intensity scales for ease of comparison. The table beside each graph shows the maximum rainfall depths and corresponding Atlas 14 recurrence intervals for durations from 1 to 24 hours.

Inspection of the hyetographs, hydrographs, and rainfall frequency data In Appendices A and B leads to the following general observations:

- High flows in Indian and Tomahawk Creeks have resulted from storms with a wide variety of durations and temporal patterns. No single duration or temporal pattern can be considered typical.

- Many of the storm events included multiple periods of high-intensity rainfall separated by periods of little or no rain.

- In none of the 22 events did rain fall continuously for a duration of 12 or more hours. The duration of continuous rainfall is shorter than 6 hours in most cases and shorter than 3 hours in many cases.

- The recurrence intervals of the maximum rainfall depths vary considerably with duration.

- The recurrence interval of the peak flow can exceed the recurrence intervals of the maximum rainfall amounts of all relevant durations if antecedent moisture conditions are unusually wet. The 10/04/1998 event provides one such example.

4. NOAA's Statistical Data on Rainfall Temporal Patterns

NOAA has developed statistical data on the temporal distributions of heavy rainfalls throughout the U.S. The methodology and the findings for the Midwestern States study area are summarized in Appendix A.5 of NOAA Atlas 14, Volume 8 (2013). NOAA's database consisted of hourly rainfall data for events with 6-hour, 12-hour, or 24-hour rainfall totals with recurrence intervals of 2 years and above. Separate statistics were developed for the four different regions of the Midwestern States study area shown in Figure 5. Johnson County lies within the Region

3, South Plains. NOAA's database for Region 3 included 8903 events of 6-hour duration, 9097 events of 12-hour duration, and 8635 events of 24-hour duration. It is important to note that the listed duration is the duration of the analysis period rather than the duration of continuous rainfall. NOAA's analysis periods always start with active rainfall, but in many cases, rainfall ceases before the analysis period ends.

NOAA further classified the events according to the quartile of the duration with the most rainfall. Table 2 shows, for each duration, the percentages of events with the heaviest rainfalls in the first, second, third, and fourth quartiles. First-quartile events are by far the most common for all three durations. One should note that NOAA defined the quartiles for the 6-hour duration unconventionally. The first quartile was defined as the first hour, the second quartile as the second and third hours, the third quartile as the fourth hour, and the fourth quartile as the fifth and six hours. If the quartiles had been defined conventionally with equal durations of 90 minutes, the percentage of first-quartile events would have been well over 50%.

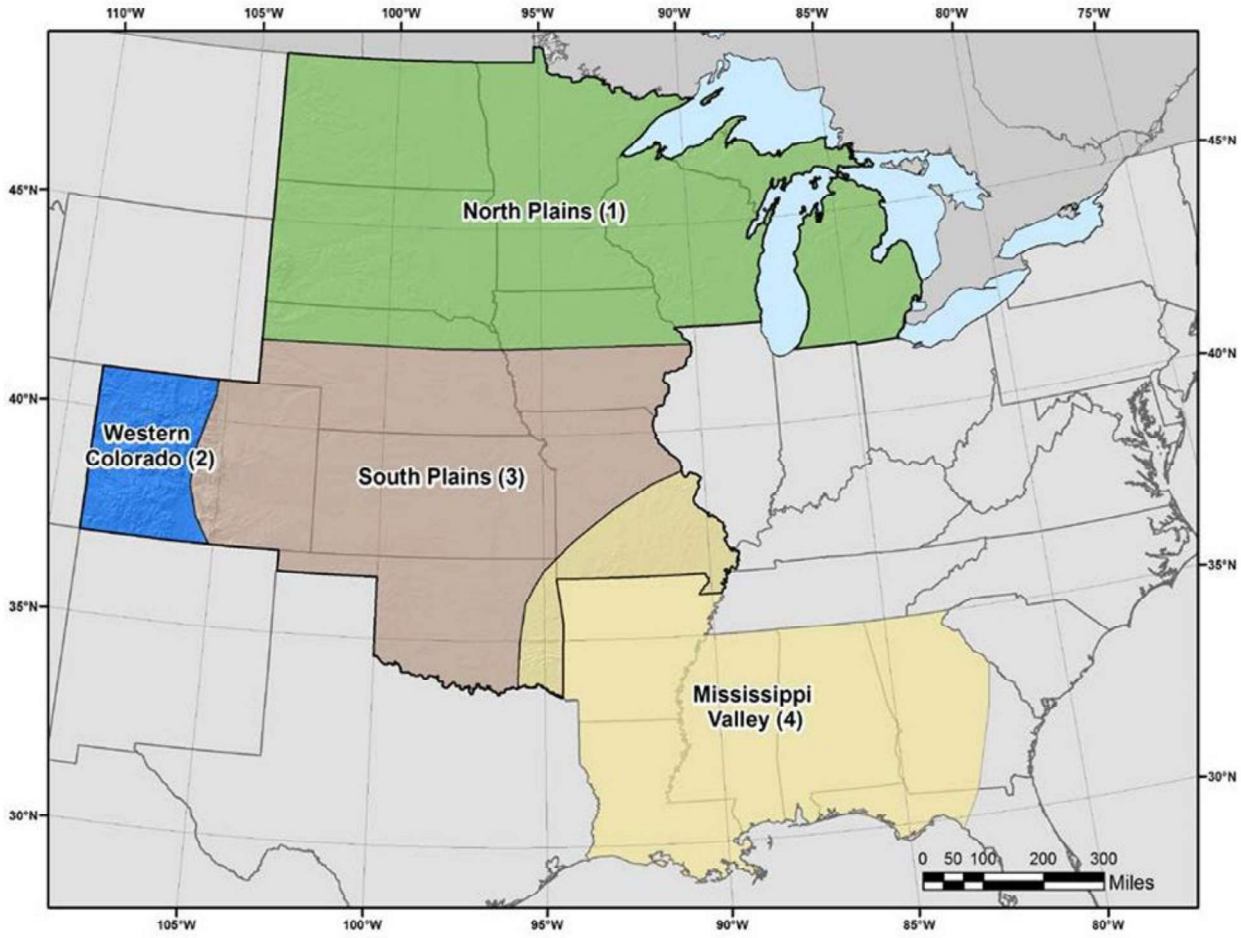

Figure 5. Four climate regions delineated in NOAA Atlas 14 Volume 8

Table 2. Distribution of rainfall events by quartile of duration with heaviest rainfall in NOAA's South Plains region

Duration (hours)	Percentage of events of stated duration with heaviest rainfall in stated quartile of duration			
	1st quartile	2nd quartile	3rd quartile	4thquartile
6	48%	29%	16%	7%
12	56%	22%	14%	8%
24	52%	18%	17%	13%

For each of the three observational durations (6, 12, and 24 hours), NOAA computed frequency distributions for the cumulative percentage of the total rainfall at half-hour intervals. Figures 6, 7, and 8 show these results graphically. The curve labels represent the exceedance probabilities of the cumulative percentages of total rainfall. On each graph, the solid 50% curve represents the median relationship. The plotted curves are composite statistical results for thousands of events rather than representative temporal patterns for individual events. Hyetographs of individual storms are generally quite irregular, but those irregularities disappear when the temporal patterns of many different storms are averaged together.

NOAA's statistical results for 6-hour, 12-hour, and 24-hour durations show that the rainfall temporal distributions for these durations are, on average, markedly front-loaded. In the median case for the 6-hour duration, 50% of rain falls in the first third of the duration and 73% falls in the first half. In the median case for the 12-hour duration, 58% of rain falls in the first third of the duration and 80% falls in the first half. In the median case for the 24-hour duration, 52% of the rain falls in the first third of the duration and 73% falls in the first half.

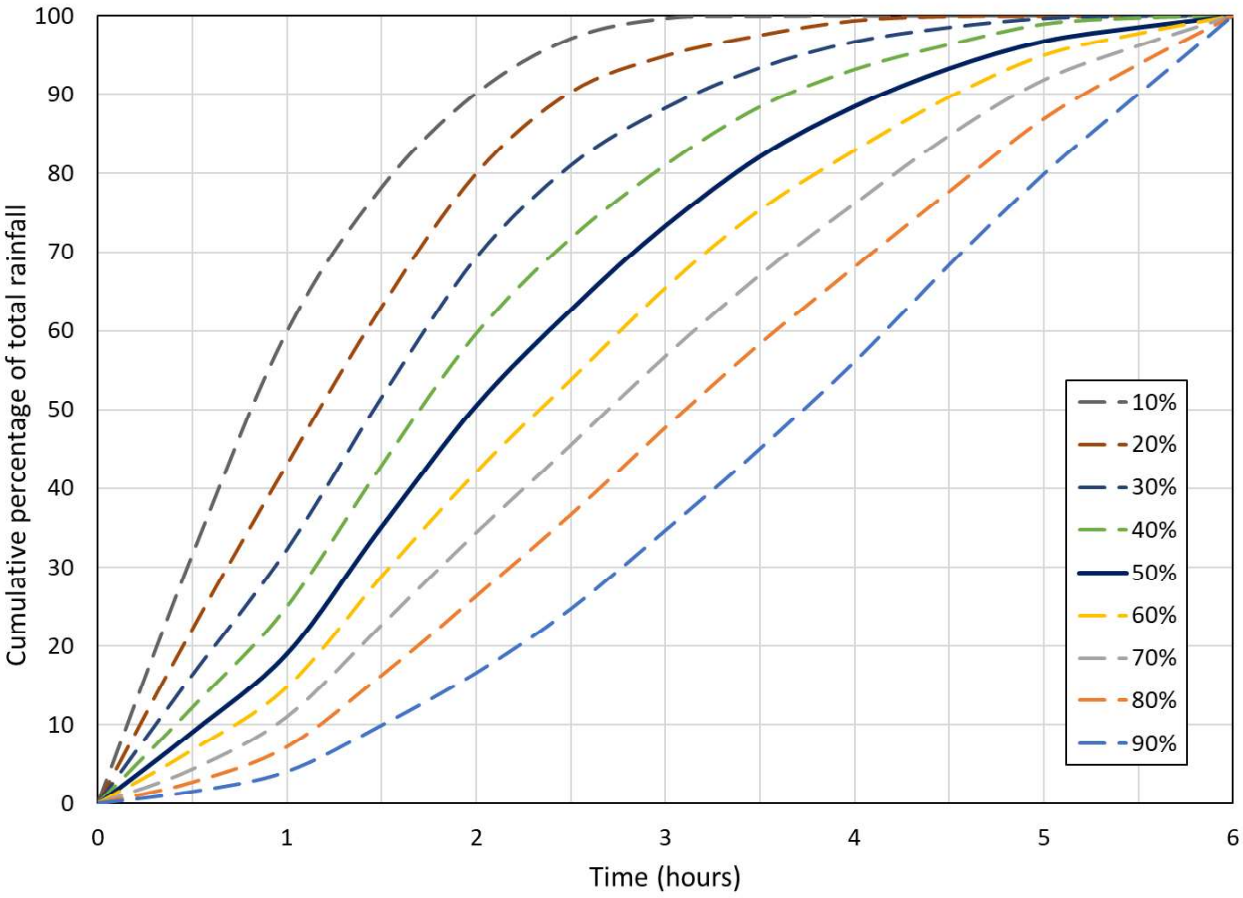

Figure 6. NOAA's frequency distribution for cumulative percentage of total rainfall versus time for 6-hour events in the South Plains region

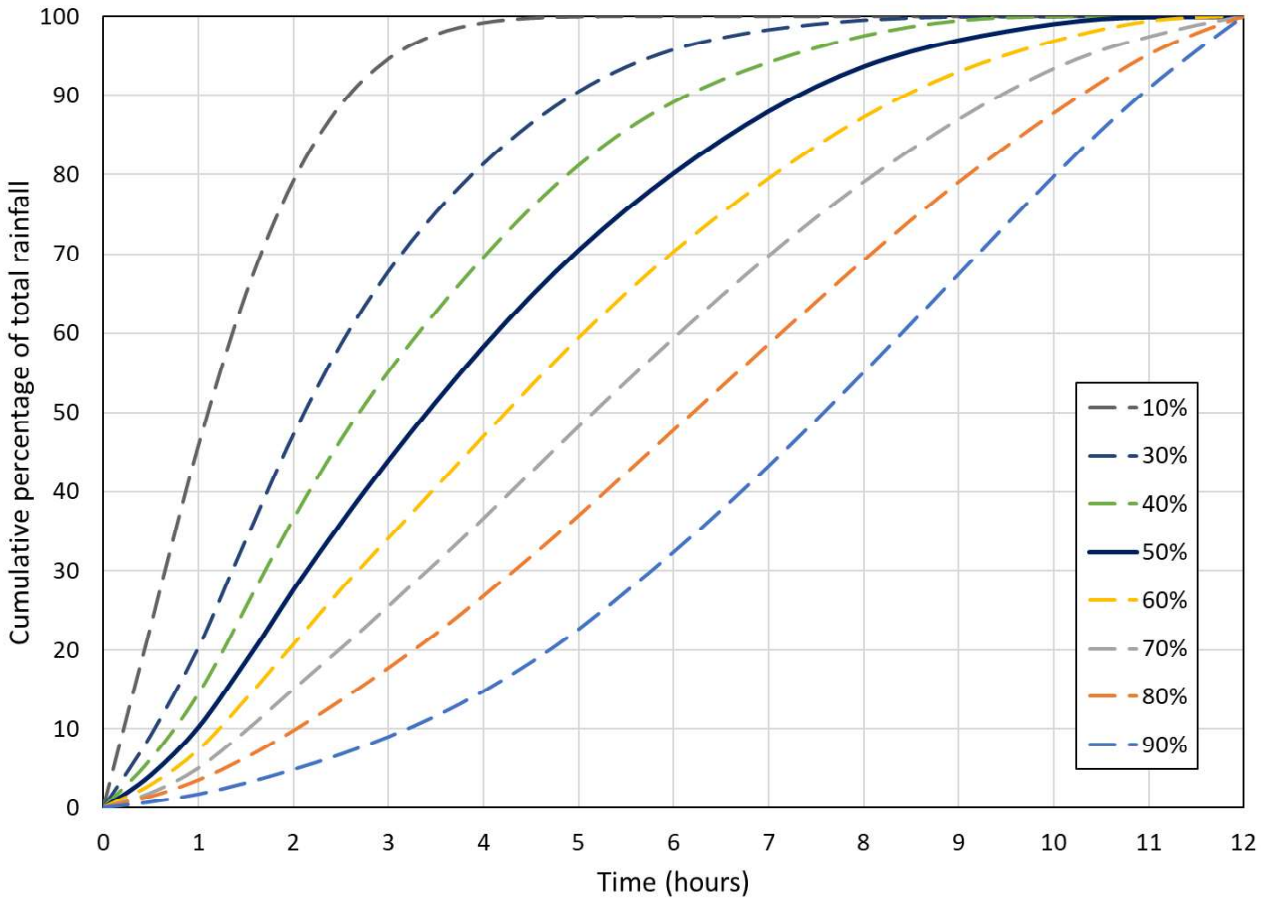

Figure 7. NOAA's frequency distribution for cumulative percentage of total rainfall versus time for 12-hour events in the South Plains region

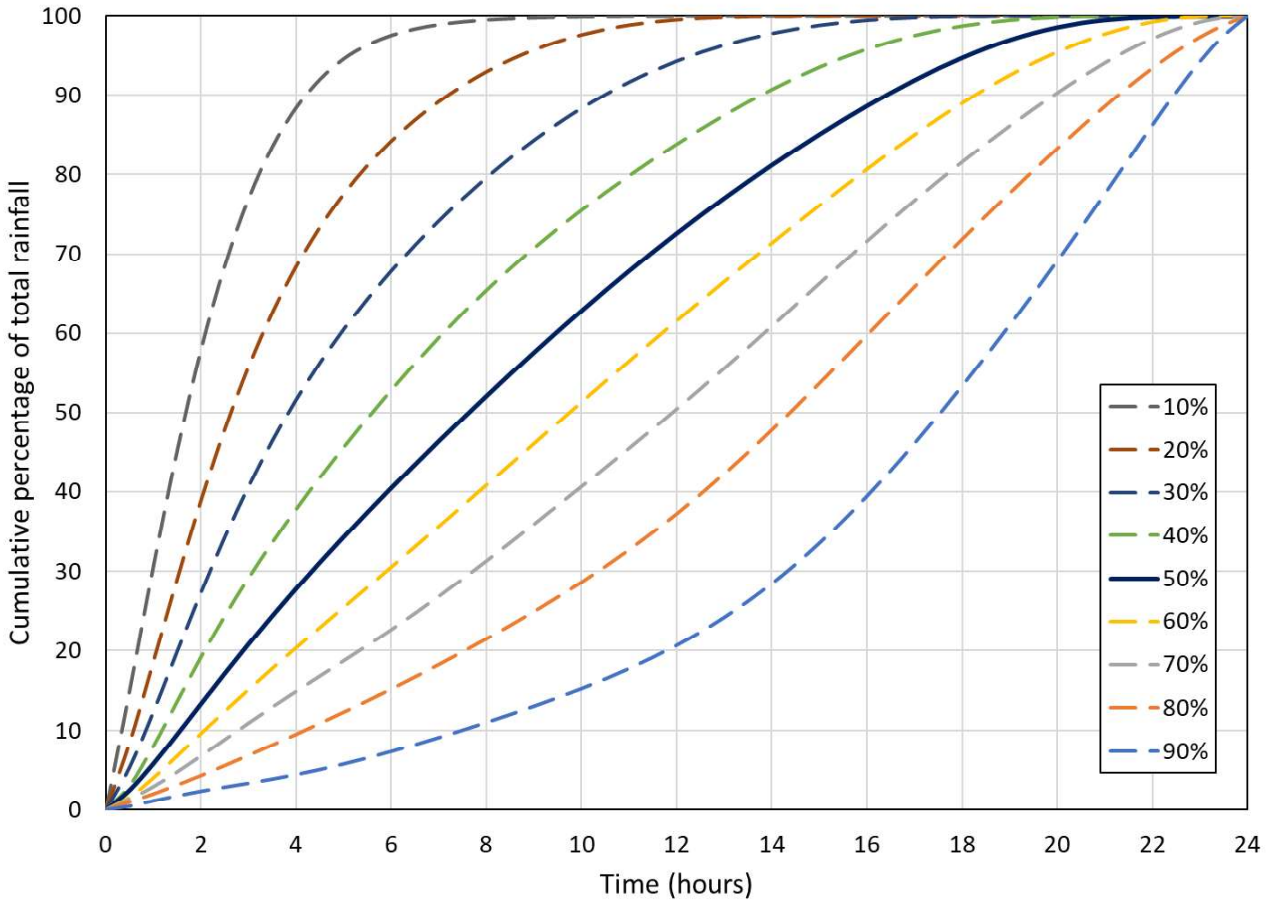

Figure 8. NOAA's frequency distribution for cumulative percentage of total rainfall versus time for 24-hour events in the South Plains region

5. Nested Synthetic Storms for Flood Studies

In flood studies, it is generally assumed that the discharge with a specified annual exceedance probability (AEP) at a given point along a stream is produced by rainfall with the same AEP over a duration equal to the hydrologic lag time or time of concentration at that point. That period of heavy rainfall might be embedded within a storm of longer duration, with rainfall distributed over the duration in a particular temporal pattern. An average antecedent moisture condition is generally assumed. The key variables are the overall duration of the synthetic storm and the temporal distribution of the rainfall within the storm.

Where a single flood model must account for flood conditions at multiple locations with widely differing times of concentration, a nested-type synthetic storm is most appropriate. In a nested storm, the rainfall is distributed over the storm duration so that the maximum rainfall depth of any shorter duration has the same AEP as the total storm rainfall. For example, within a nested storm of 24-hour duration, the maximum rainfall depths over durations of 1, 2, 3, 6, and 12

hours would all have the same AEP as the 24-hour rainfall depth. The key variables for a nested synthetic storm are the total duration of the storm and the time to the peak intensity.

Appendix C presents a step-by-step procedure for developing a nested hyetograph with desired values of rainfall frequency, duration, time to peak intensity, and rainfall time interval.

The HEC-HMS (Hydrologic Modeling System) program of the U.S. Army Corps of Engineers includes a nested storm option, termed the "frequency storm." The duration of the frequency storm can be set to 1, 2, 3, 6, 12, or 24 hours (or longer), and the peak intensity can be set to occur at 25%, 33%, 50%, 67%, or 75% of the storm duration. The rainfall inputs for an n%-chance frequency storm of 24-hour duration are the n%-chance rainfall depths for durations of 5, 10, 15, and 30 minutes and 1, 2, 3, 6, 12, and 24 hours.

The most common synthetic storm model for flood studies is a 24-hour nested storm with a 12-hour time-to-peak. However, in many cases this storm model may not be the most appropriate one. In our region, the periods of intense rainfalls that produce flooding on small urban watersheds typically occur within convective storms with shorter durations than the large-scale frontal events that produce extreme 24-hour rainfalls. A synthetic storm model that combines extreme rainfalls of all durations out to 24 hours could be overly conservative. The placement of the peak intensity at the midpoint of the storm duration might also be inappropriate. NOAA's statistical data show that temporal distributions of heavy rainfalls in our region tend to be strongly front-loaded. This finding is important because front-loaded storms produce lower peak flows than back-loaded storms.

The effects of a nested storm's duration and time-to-peak on computed peak flow was investigated with a simple HEC-HMS model of the Indian Creek watershed. The model was calibrated to match the peak flow, time-to-peak, and runoff volume for the 8/22/17 flood event at the Marty Street gage, with the rainfall record from that location as the precipitation input. The calibrated model was run with 1%-chance nested storms of 24-hour and 12-hour duration with peak intensities at 50% and 25% of those durations. Table 3 shows the computed peak flows and their relative differences from the result for the 24-hour storm with the 12-hour time-to-peak.

Table 3. Preliminary test of sensitivity of peak flow to nested storm characteristics

1%-AEP nested storm		Indian Creek at Marty Street	
Duration (hours)	Time-to-peak (hours)	Peak flow (cfs)	Change from baseline*
24	12	15,701	-----
24	6	14,663	-6.6%
12	6	14,663	-6.6%
12	3	13,732	-12.5%

*Baseline storm: 24-hour duration, 12-hour time-to-peak

These results show that the nested storm's time-to-peak has a substantial impact on the peak flow. Shortening the 24-hour storm's time-to-peak from 12 to 6 hours reduces the peak discharge by more than 6%. Shortening the 12-hour storm's time-to-peak from 6 to 3 hours also reduces the peak discharge by more than 6%. However, the 24-hour and 12-hour storms with 6-hour times-to peak yield identical peak flows, which shows that the amount of rain that precedes the peak matters much more than the amount of rain that falls after the peak.

6. Temporal Patterns Derived from NOAA's Statistical Distributions

Some flood modelers distribute synthetic storm rainfall in temporal patterns derived from NOAA's statistical distributions. That approach is evaluated here by examining five 1%-chance, hyetographs for Indian Creek derived from NOAA's statistical tables for the 24-hour duration. Those tables provide values of cumulative percentage of total rainfall versus time at 30-minute intervals for exceedance probabilities from 10% to 90%. The five hyetographs, plotted in Figure 9, were developed from the cumulative rainfall percentages exceeded by 10% of all events, 50% of all events, 90% of all events, 10% of first-quartile events, and 90% of fourth-quartile events in the South Plains region. Those five hyetographs span the range of NOAA's statistical findings for the 24-hour duration. At the extremes, the 10% first-quartile temporal pattern is more front-loaded than 95% of all events in NOAA's dataset, and the 90% fourth-quartile pattern is more back-loaded than 99% of all events in the dataset. The other three patterns cover the middle ground. Three of the five hyetographs have effective durations much shorter than 24 hours. The other two hyetographs have very low intensities at all times.

Table 4 shows the maximum depths of rainfall for durations of 30 minutes and 1, 2, 3, 6, and 12 hours for the five hyetographs. Included and highlighted for comparison are the maximum depths for the 24-hour nested storm, which are the 1%-chance depths from Atlas 14. Table 5 shows the recurrence intervals of the maximum depths in Table 4. The five hyetographs derived from NOAA's statistical data all contain maximum rainfall depths for durations shorter than 24 hours that differ greatly from the 1%-chance depths from Atlas 14. The maximum 30-minute depths are much too low in all five cases. For the 50% and 90% all-event hyetographs, the maximum depths are much too low for all durations up to 12 hours. On the other hand, for the 10% all-event and 10% first-quartile hyetographs, the maximum depths for the intermediate durations have recurrence intervals far in excess of 100 years.

These findings indicate that none of the NOAA-based temporal patterns would work well in a flood model that must provide reasonable estimates of flood levels with a consistent recurrence interval at multiple locations with widely differing times of concentration. When the 24-hour rainfall is distributed in any of the five patterns, the maximum rainfalls depths for durations of 30 minutes and 1, 2, 3, 6, and 12 hours have recurrence intervals that differ greatly from the recurrence interval of the 24-hour rainfall.

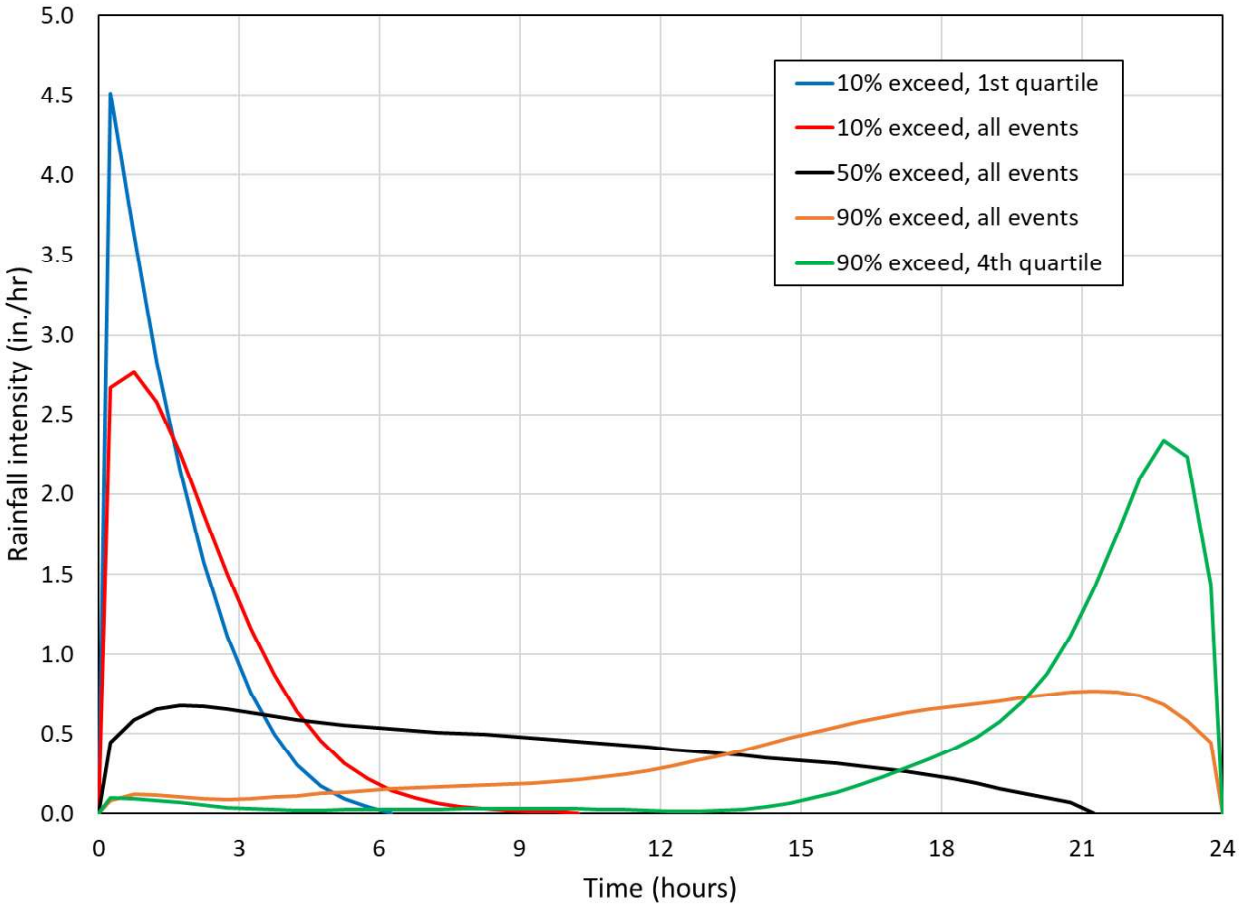

Figure 9. 1%, 24-hour hyetographs for Indian Creek with five NOAA temporal distributions

Table 4. 1%-chance 24-hour synthetic storms for Indian Creek: maximum depth vs. duration

Temporal distribution for 1%-AEP 24-hr storm	Maximum rainfall depth of stated duration (inches)						
	30 min	1	2 hr	3 hr	6 hr	12 hr	24 hr

NOAA 90%, 4th quartile	2	10	61	139	246	152	100

7. Areal Reduction of Rainfall

The rainfall depths in NOAA Atlas 14 are point values that apply to specific locations. The n%-chance value of the spatially averaged rainfall over a watershed is always less than the n%-chance point rainfall. The ratio of the spatially averaged depth to the point depth for the same duration and frequency is termed the areal reduction factor (ARF). ARF values vary with the watershed size and the specified duration. The relevant rainfall duration is generally the time of concentration or lag time to the point of interest. The larger the watershed and the shorter the duration, the smaller the ARF value. Table 6 shows ARF values obtained from equations fitted to the widely accepted curves published by the U.S. Weather Bureau in 1958 (McEnroe and Young, 2007).

Table 6. Areal reduction factors for rainfall

Area (mi^2)	Areal reduction factors for rainfall of specified duration							
	5 min	15 min	1 hr	2 hr	3 hr	6 hr	12 hr	24 hr
1	0.985	0.990	0.995	0.996	0.997	0.998	0.998	0.999
2	0.970	0.981	0.990	0.992	0.993	0.995	0.996	0.997
5	0.926	0.954	0.974	0.981	0.984	0.988	0.991	0.993
10	0.857	0.910	0.951	0.963	0.969	0.977	0.983	0.987
20	0.733	0.833	0.908	0.932	0.943	0.957	0.968	0.976
30	0.627	0.767	0.871	0.904	0.920	0.940	0.956	0.967
40	0.536	0.710	0.840	0.881	0.900	0.926	0.945	0.959
50	0.457	0.661	0.813	0.861	0.883	0.913	0.935	0.952
60	0.390	0.619	0.789	0.843	0.868	0.902	0.927	0.946
70	0.332	0.582	0.769	0.828	0.856	0.893	0.920	0.941

When the objective of a hydrologic calculation or model is the n%-chance discharge or stage at a single location, the appropriate ARF values can be applied to the n%-chance rainfall depths of the different durations. However, in a watershed study where n%-chance conditions are needed at multiple points with different times of concentration, no single set of ARF values will suffice. Multiple model runs with different ARF values would be needed to determine the n%-chance flood levels at multiple locations with different drainage areas. The HEC-HMS hydrologic modeling system incorporates a "depth-area analysis" feature that makes multiple model runs with ARF values for different drainage areas and then estimates the n%-chance conditions at the various locations by interpolation. However, HEC-RAS 2D does not have that capability. Making multiple model runs with ARF values applied to the point rainfall then interpolating the results is infeasible in HEC-RAS 2D due to the excessive runtimes that would be needed.

Some flood modelers have attempted to account for the areal reduction of rainfall by trimming off the leading and trailing tails of the nested hyetograph. In this scheme, the total storm depth is reduced to the desired value by shortening the storm duration without altering the rainfall intensities within the remainder of the storm. Tests performed as part of this investigation indicate that this scheme does not achieve the desired objective. Trimming the hyetograph's tails reduces peak flows by similar percentages at points with widely differing drainage areas fact. This result is unrealistic. The impact of the areal reduction of rainfall on peak flows should be negligible for small drainage areas and increase in the downstream direction.

In fact, there is no way to properly account for the areal reduction of rainfall at different locations in a HEC-RAS 2D flood model without making multiple model runs. However, neglecting the areal reduction of rainfall in the Indian Creek watershed study will not affect the results much. At State Line Road, Indian Creek has a drainage area of 64.2 square miles and a time of concentration on the order of 6 hours. The ARF value for that drainage area and time of concentration is 0.90. At its confluence with Tomahawk Creek, 0.8 miles upstream of State Line Road, Indian Creek's drainage area is 38 square miles and the applicable ARF value is 0.93. At most other locations of interest in the two watersheds, drainage areas are much smaller and ARF values for relevant rainfall durations are closer to 1.0.

8. Selection of Nested Storm for Indian and Tomahawk Creek Flood Studies

The peak discharge produced by an n%-chance nested storm depends on the storm's duration and time-to-peak. The objective is to find a combination of duration and time-to-peak that produces a peak discharge with the same recurrence interval as the storm rainfall. This investigation focuses on the Indian and Tomahawk Creek watersheds, but the findings and recommendations might also be applied to flood models of other Johnson County watersheds, so the characteristics of those watersheds should be considered.

FEMA's guidance states that the duration of the synthetic storm must exceed the longest time of concentration in the watershed. The times of concentration of the Indian and Tomahawk

Creek watersheds are no longer than 6 hours, but the Cedar Creek and Kill Creek watersheds in western Johnson County are larger and less developed and therefore have longer times of concentration. Cedar Creek and Kill Creek each have a USGS discharge gage located near the lower end of the watershed and several ALERT rainfall gages located in and around the watershed. The lag times of Cedar Creek and Kill Creek were estimated by calibrating a simple HEC-HMS model of each watershed with ALERT rainfall data and USGS streamflow data for the event of 7/27/2017. Best-fit values of runoff curve number and lag time were computed with the HEC-HMS parameter optimization feature. Time of concentration was assumed to equal five-thirds of lag time. Cedar Creek at 83rd Street (USGS station 682495) was found to have a lag time of 5.9 hours and a corresponding time of concentration of 9.9 hours. Kill Creek at 95th Street (USGS station 682360) was found to have a lag time of 6.0 hours and a time of concentration of 10.0 hours. These findings indicate that a synthetic storm template to be applied throughout Johnson County should have a duration of 10 hours or longer.

The HEC-RAS 2D flood models for Indian and Tomahawk Creeks were calibrated for two major historical flood events at the three USGS gages. As a separate task, further calibration was recently completed for other major events, including the 8/22/2017 flood of record, using data from the ALERT gage network. For most events, at most stage-gage sites, the computed peak stages are reasonably close to the recorded values. However, for a reason yet undetermined, the computed peak stages for Indian Creek at Marty Street are somewhat higher than the gaged values for those events. For the 8/22/2017 event, the computed peak stage at that location is 876.99 feet, 1.33 feet higher than the peak stage recorded at the ALERT gage.

The three 1%-chance nested storms shown in Figure 10 were tested in the 2D model for Indian Creek. Table 7 shows the computed peak stages. The three values are all significantly higher than the 1%-chance stage of 875.70 feet from the frequency analysis of the 1977-2022 gage data. However, the current HEC-RAS 2D model overestimates the peak stage for the 8/22/2017 flood of record by 1.33 feet at that location. The 2D model might be expected to overestimate the peak stage for the 1%-chance event by a similar amount for reasons unrelated to the synthetic storm. Of the three nested storm configurations, the 12-hour storm with the 3-hour time-to-peak yields the 1%-chance flood level closest to the value from the frequency analysis of the USGS gage data.

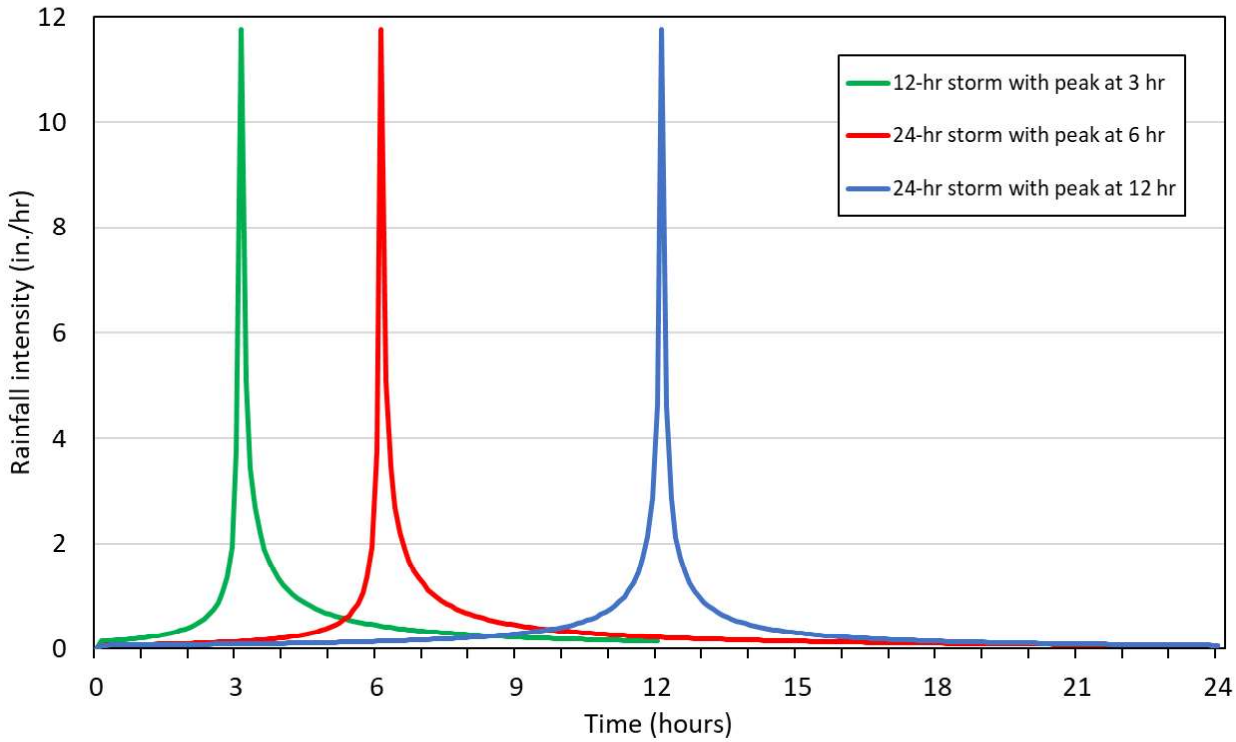

Figure 10. 1%-chance nested storms with different durations and times-to-peak

Table 7. HEC-RAS 2D peak stages in Indian Creek at the Marty Street gage for three 1%-chance nested storms

Storm duration (hours)	Storm time-to-peak (hours)	Peak stage (feet)
24	12	878.11
24	6	877.51
12	3	877.34

9. Recommended Synthetic Storm

The recommended storm configuration for the Indian and Tomahawk Creek flood models is a nested storm of 12-hour duration with a 3-hour time-to-peak. A nested storm is the best option for computation of flood levels with a consistent recurrence interval at locations with widely varied times of concentration in a single model run. Of the three configurations tested in the 2D model, the 12-hour with the 3-hour time-to-peak yielded the most realistic value for

the 1%-chance stage at the gage site with the longest record. The hyetographs from the high-flow events from 1993 to present in Appendices A and B provide support for a nested storm duration of 12 hours rather than 24 hours. In none of those historical events did rain fall continuously for more than 12 hours. NOAA's statistical findings for heavy 12-hour rainfalls provide support for the recommended 3-hour time-to-peak. In NOAA's median temporal distribution for the 12-hour duration, 50% of the total rainfall occurs in the first 3.4 hours. The 12-hour nested storm with a 3-hour time-to-peak matches that characteristic exactly.

Figure 10 compares the hyetographs of the recommended 1%-AEP synthetic storm (nested, 12-hour duration, 3-hour time-to-peak) and the 8/22/2017 flood-of-record event at the Marty Street gage. The start of the shorter 8/22/2017 event is lagged to align the timing of the peak intensities. This comparison highlights the difference between a synthetic rainfall event with a single peak and a real rainfall event with multiple peaks and a more random-appearing temporal pattern.

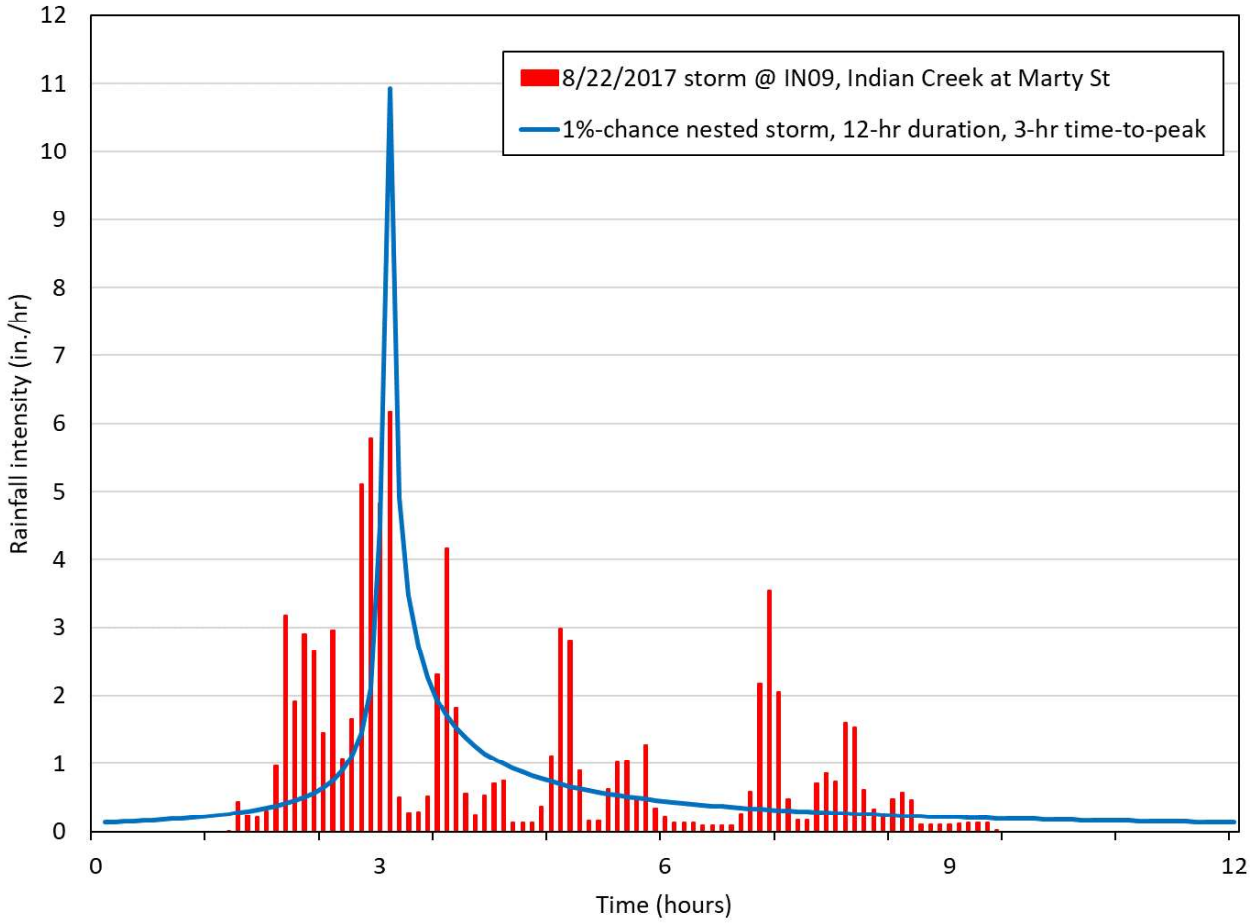

Figure 10. Comparison of recommended 1%-chance nested storm and rainfall on 8/22/2017

No areal reduction factor should be applied to the storm rainfall. There is no practical way to account for the areal reduction of rainfall at different locations in a single HEC-RAS 2D model run. Neglecting the areal reduction of rainfall in the Indian and Tomahawk Creek flood models will have an insignificant impact on the computed peak flows.

Appendix C – Development of Nested Storm Hyetographs

This appendix presents a method for developing a hyetograph for a nested storm with a desired duration and time-to-peak.

First, the depth-duration data for the desired annual exceedance probability (AEP) must be fitted with a continuous relationship to facilitate interpolation between tabulated durations and smooth out any irregularities. This is best done by fitting a polynomial equation to the base-10 logarithms of the depth and duration data. The process is demonstrated here using the 1%-AEP data for Indian Creek at Marty Street from Atlas 14. Table C1 shows the Atlas 14 depth-duration data and the base-10 logarithms of those values.

Table C-1. 1%-AEP rainfall depth-duration data for Indian Creek at Marty Street

Duration	Depth (inches)	log of duration in hours	log of depth in inches
5 min	1.06	-1.079	0.0253
10 min	1.56	-0.778	0.193
15 min	1.90	-0.602	0.279
30 min	2.70	-0.301	0.431
60 min	3.65	0.000	0.562
2 hr	4.60	0.301	0.663
3 hr	5.30	0.477	0.724
6 hr	6.56	0.778	0.817
12 hr	7.82	1.079	0.893
24 hr	8.86	1.380	0.947

Figure C-1 shows a plot of log(depth) vs. log(duration) and the trendline and corresponding equation fitted to those data with Excel's Add Trendline feature. A polynomial equation was chosen and its order was varied to achieve the best fit. In this example, a second-order polynomial equation fits the data well. In the displayed equation, x is the base-10 logarithm of duration in hours and y is the base-10 logarithm of depth in inches. The corresponding equation relating depth D in inches to duration z in hours is:

$$D = 10^{-0.08420 [\log(z)]^2 + 0.4008 \log(z) + 0.5556}$$

Excel allows the user to select the display mode for the coefficients in the fitted equation. The coefficients should be displayed in scientific notation with three decimal places. If the coefficients are rounded to fewer significant figures, the displayed equation might not fit the data as well as the trendline on the graph, which is computed with unrounded coefficients.

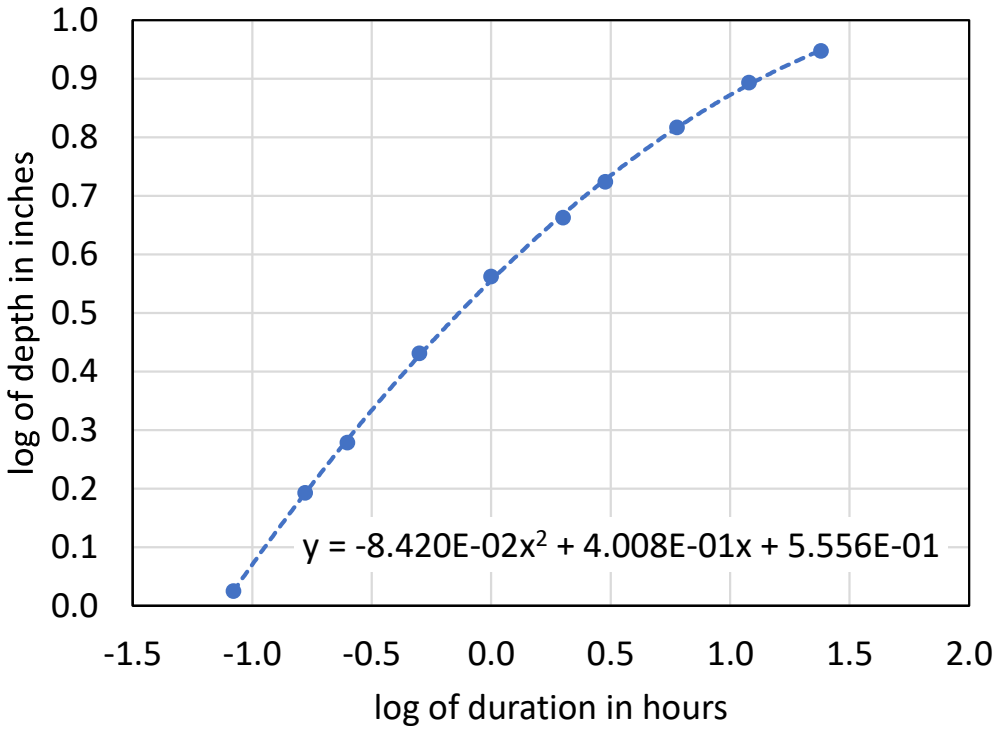

Figure C-1. Log-log plot of 1%-chance depth-duration data with fitted equation

Table C-2 compares the 1%-AEP rainfall depths from Atlas 14 and depth values from Atlas 14 with those computed with the fitted equation. The differences minor.

Table C-2. Comparison of 1%-AEP rainfall depths from Atlas 14 and fitted equation

Duration	Depth (inches)	
	Atlas 14	Fitted equation
5 min	1.06	1.06
10 min	1.56	1.56
15 min	1.90	1.92
30 min	2.70	2.67
60 min	3.65	3.59
2 hr	4.60	4.66
3 hr	5.30	5.34
6 hr	6.56	6.55
12 hr	7.82	7.76
24 hr	8.86	8.88

A hyetograph for a nested design storm can be developed from the fitted depth-duration equation in a spreadsheet table. Three hyetograph characteristics must be specified: the storm duration, the time-to-peak, and the time interval for the rainfall data. The storm duration and the time-to-peak must be whole multiples of the specified time interval. The time-to-peak is defined as the time to the start of the time interval with highest intensity. The equations used to develop the hyetograph incorporate the following notation:

- t = time from start of storm
- Δt = time interval for rainfall data (input)
- t_d = duration of storm (input)
- t_p = time-to-peak = time to start of time interval with greatest intensity (input)
- t_c = pivot time for distribution of n%-AEP rainfalls of different durations
- z = duration of n%-AEP rainfall starting at time t (for $t < t_c$) or ending at time t (for $t > t_c$)
- $D(z)$ = depth of n%-AEP rainfall for duration z, from fitted depth-duration equation
- P = cumulative rainfall depth at time t
- ΔP = incremental rainfall depth over time interval ending at time t
- R = average rainfall intensity over time interval ending at time t

The n%-AEP rainfall depths for all durations from Δt to t_d are distributed around a pivot time, t_c, located within the interval of greatest intensity as follows:

$$t_c = t_p + \left(\frac{t_p}{t_d}\right)\Delta t$$

The n%-AEP rainfall depths for all durations are distributed so that the fraction of the depth occurring before time t_c equals t_c/t_d and the fraction occurring after time t_c equals the $1 - t_c/t_d$.

The following equations are used to compute the cumulative depths for times from 0 to t_d at intervals of Δt. Incremental depths and intensities follow directly from the cumulative depths.

$$z = \begin{cases} \left(1 - \dfrac{t}{t_c}\right) t_d, & t < t_c \\ \left(\dfrac{t - t_c}{t_d - t_c}\right) t_d, & t > t_c \end{cases}$$

$$R = \begin{cases} \dfrac{t_c}{t_d}[D(t_d) - D(z)], & t < t_c \\ \dfrac{t_c}{t_d} D(t_d) + \left(1 - \dfrac{t_c}{t_d}\right) D(z), & t > t_c \end{cases}$$

Example

Develop a hyetograph table at 0.2-hour intervals for a nested storm with duration of 6 hours and a time-to-peak of 2.4 hours.

Δt = 0.2 hours
t_d = 6.0 hours
t_p = 2.4 hours

$$t_c = 2.4 + \left(\frac{2.4}{6.0}\right) 0.2 = 2.44$$

Applying the equations for z and R for times from 0 to 6 hours at 0.2-hour intervals yields the cumulative depths, incremental depths, and intensities shown in Table C-3. Note that the maximum values of incremental depth and intensity occur in the 0.2-hour time interval from 2.4 to 2.6 hours.

Table C-3. Incremental quantities for example nested hyetograph

JOHNSON COUNTY KANSAS
Public Works

To: **Dawn Livingston**
Project Manager - Mitigation Division
FEMA Region 7

From: **Sarah Smith, PE**
Lead Program Engineer
Johnson County Stormwater Management Program

Subject: CTP – Alternate Hydrology
Response to FEMA Comments from 2/13/2024

Date: **2/21/2024**

This memo presents responses to the four storm-related comments in FEMA's 2/13/2024 review of Johnson County's Alternative Hydrology Memorandum. The italicized bullet points are FEMA's comments.

- *In Appendix A of Dr. McEnroe's report, the 8/22/2017 and 7/27/2017 events each show significant rainfall amounts in the first 1-2 hours of the 24-hour storm events. The majority of the rainfall occurs between hours 12 and 24 of the events, supporting the use of the 12-hour duration. However, it could be argued that the presence of significant rainfall in the initial hours of the event may have resulted in saturated conditions creating larger peak discharges than would have resulted with use of 12-hour design storm.*

We agree that the wetter soil conditions caused by antecedent rainfall can increase runoff volumes and peak discharges. However, we think the proposed 12-hour storm duration adequately accounts for that concern. The 8/22/17 event had a total duration of 20 hours, but the duration of active rainfall was less than 8 hours. The 12-hour break between the initial burst of heavy rainfall in the early morning and the much larger event in the afternoon gave the soil's infiltration capacity a change to recover slightly. The event of 7/27/2017 also had a total duration of almost 20 hours, but the duration of active rainfall was only 6 hours.

- *Although the report describes in detail the NOAA temporal distributions, the discussion of why these temporal distributions are not appropriate is limited to consideration of the five cases of the 24-hour NOAA temporal distributions. Would not a more convincing case be made by considering the 12-hour NOAA temporal distributions and evaluating the 50th percentile cases for each of the four quartile storm types?*

We agree that an analysis of the NOAA's 50th-percentile temporal distributions for the 12-hour duration would be helpful. The analysis of the 10th-percentile and 90th-percentile distributions is repeated here for the 50th-percentile distributions from the four quartile groups.

Figure 1 shows 12-hour hyetographs with the 1%-ACE, 12-hour rainfall of 7.82 inches (the Atlas

14 value for Indian Creek at Marty Street) distributed according to the median (50%) patterns for the four quartiles and for the entire dataset. (The first-quartile storms comprise 56% of the events in the dataset.) The median distributions for the four quartile groups exhibit much less temporal variability than is seen in the hyetographs of the actual storms in Appendices A and B of the research report. The temporal averaging process smooths out the peaks on the individual storm hyetographs because those peaks occur at different times.

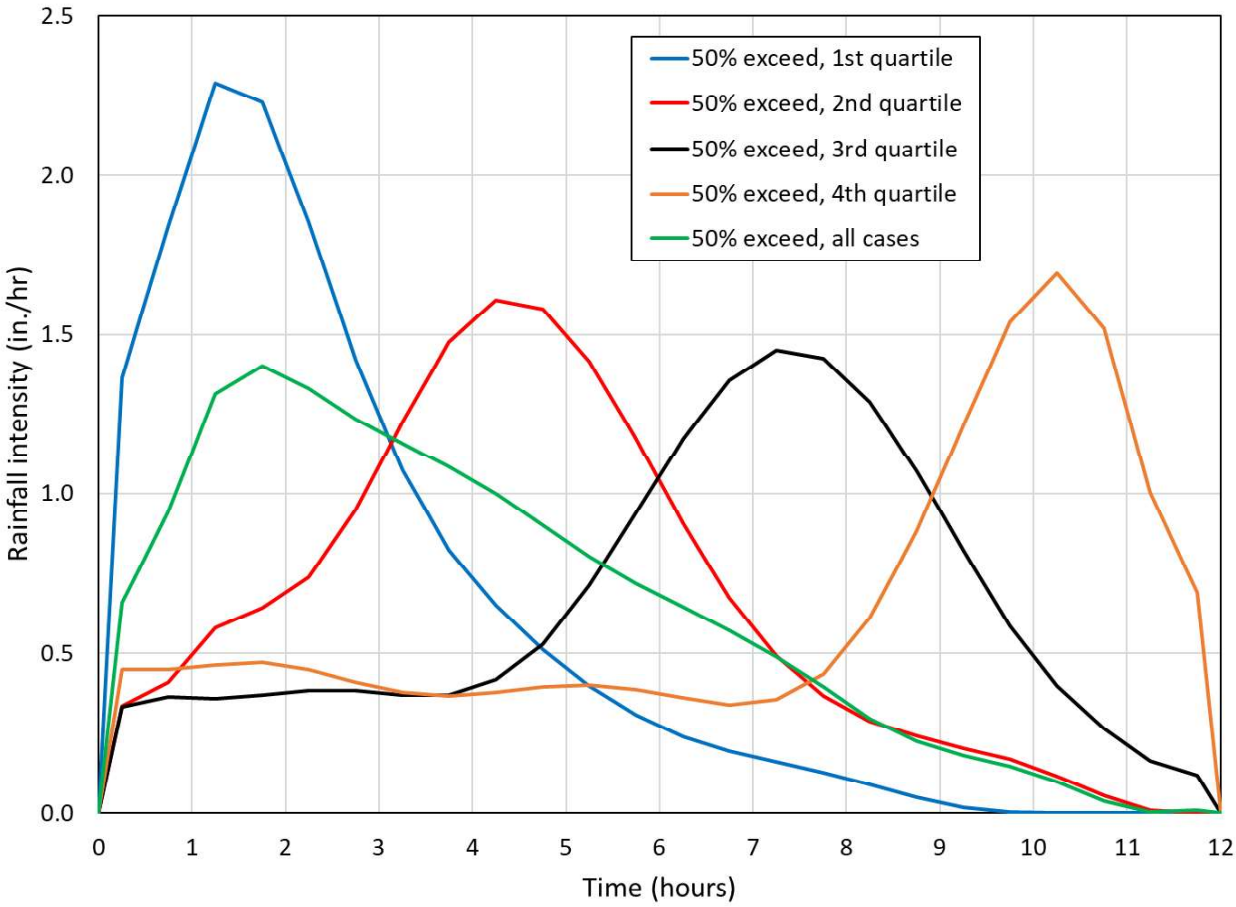

Figure 1. 1%, 12-hour hyetographs for Indian Creek with five NOAA temporal distributions

Table 1 shows the maximum depths of rainfall for durations of 30 minutes and 1, 2, 3, 6, and 12 hours for the five hyetographs. Included and highlighted for comparison are the maximum depths for the 12-hour nested storm, which are the 1%-chance depths from Atlas 14. Table 2 shows the recurrence intervals of the maximum depths in Table 1. The five hyetographs derived from NOAA's median distributions for the four quartile groups and the entire dataset contain maximum rainfall depths for durations shorter than 12 hours that differ greatly from the 1%-chance depths from Atlas 14. The maximum depths for durations of three hours and shorter are much too low for the 2nd-, 3rd-, and 4th-quartile groups and all cases. Distributing the synthetic storm rainfall in any of these patterns would result in substantial underestimation of the 1%-ACE discharges throughout the Indian and Tomahawk Creek watersheds. The

maximum depths for the 1st-quartile group are too low for the shorter durations and too high for the longer durations. Distributing the synthetic storm rainfall in that pattern would result in underestimation of the 1%-ACE discharges at locations with times of concentration of one hour or less.

Table 1. 1%-chance 12-hour synthetic storms for Indian Creek: maximum depth vs. duration

Temporal distribution for 1%-ACE 12-hr storm	Maximum rainfall depth of stated duration (inches)					
	30 min	1	2 hr	3 hr	6 hr	12 hr
Nested	**2.70**	**3.65**	**4.60**	**5.30**	**6.56**	**7.82**

NOAA 50%, all events	<2	2	7	19	79	100

- *Although the justification for use of the 12-hour, 3-hour to peak storm is reasonable, the overall result of using the shorter storm duration instead of the 24-hour, 12-hour to peak storm is to reduce the magnitude of the modeled 1% annual chance of exceedance (ACE) discharge at the 06893300 Indian Creek at Overland Park (at Marty Street) location by about 13%, from 15,700 cfs to 13,730 cfs. The 1% ACE discharge computed by frequency analysis at the 06893300 gage location is 15020 cfs. The modeled 1% ACE discharge using the 24-hour/12-hour to peak storm differs from the gage discharge estimate by 4.5%, while the modeled 1% ACE discharge using the 12-hour/3-hour to peak storm differs from the gage discharge estimate by -8.6%. Although both of the modeled estimates are within the standard error (68% confidence interval) of the 1% ACE gage estimate, the modeled 1% ACE estimate using the 12-hour/3-hour to peak storm differs from the gage estimate by more than the modeled 1% ACE estimate using the 24-hour/12-hour to peak storm. Dr. McEnroe's report presents a summary of several key points from FEMA's guidance regarding rainfall inputs to flood models and addresses the presented points in the report; however, FEMA's guidance also states that "The storm duration must also be large enough to provide reasonable runoff…". Please include*

clarification of the reasonableness of the alternative 1% ACE estimate resulting from the proposed 12-hour/3-hour to peak storm in comparison to the standard 24-hour storm duration.

Our calibration efforts are focused on flood stage rather than discharge. Our primary calibration point on Indian Creek is USGS gage 6893300, located on the downstream side of the Marty Street bridge. The recorded flood stages at that gage are reliable. However, as the research report explains, the USGS-reported discharges appear to be unreliable for floods with peak stages over 870 feet (discharges over 5000 cfs). The USGS rating curve for stages over 862 feet is a simple power function fitted to field-measurement data for stages only up to 869.32 feet. The rating curve appears to overestimate discharges for flood stages over 870 feet because it does not account for the substantial backwater effects from the bridge at 103rd Street, 650 feet downstream, with its waterway capacity exceeded.

The controlling low chord elevation of the Marty Street Bridge is approximately 877.66 feet, which is located at the downstream end of bridge. The stage-discharge curve is expected to stagnate at this elevation, with discharges steadily increasing after the bridge begins to overtop (at approximately 880.80 feet, not factoring in railing). The USGS stage-discharge curve does not reflect these breakpoints, which further attests to the unreliability of the USGS rating curve for high discharges and shows that stage is more appropriate for calibration purposes at this gage location.

Our frequency analysis of annual flood peaks 1977-2022 indicates that the 1%-ACE flood stage at the Marty Street gage is 875.70 feet. In the HEC-RAS 2D model as currently calibrated, the 12-hour nested storm with the 3-hour time-to-peak produces a peak stage at that is much closer to this target value than the 24-hour nested storm with the 12-hour time-to-peak.

- *The resulting 1% ACE modeled elevations are also compared in the report by Dr. McEnroe. As would be expected, the 12-hour duration/3-hour to peak storm yields the lowest 1% ACE estimated elevation of 877.34', which is lower by about 0.8' than the 1% ACE modeled elevation using the 24-hour/12-hour to peak storm. The 1% ACE modeled elevation using the 24-hour/6-hour to peak storm, however, is 877.51', less than 0.2' greater than 1% ACE modeled elevation using the 12-hour duration/3-hour to peak storm. This confirms the conclusion noted in Dr. McEnroe's report that "…that the amount of rain that precedes the peak matters much more than the amount of rain that falls after the peak." Please include clarification, given this comparison, of the preference for the 12-hour/3-hour to peak storm over a standard 24-hour storm duration using a 6-hour to peak distribution.*

It is true that the 12-hour nested storm with the 3-hour time-to-peak produces flood stages that are not much lower than the stages for the 24-hour storm with the 6-hour time-to-peak. Olsson's comparisons at six locations showed an average difference of 0.3 feet and a maximum difference of 0.4 feet as shown in the attachment. At the Marty Street gage, the stage for the 12/3 storm is closer to target value than the stage for the 24/6 storm but the difference is only 0.17 feet.

Feel free to reach out to us with any questions, comments, or additional documentation that is required.

Sincerely,

Sarah Smith

JULY 2024 HISTORIC EVENT

JULY 2025 HISTORIC EVENT

M INTERIOR DRAINAGE

M.2 PRECIPITATION TIME SERIES

The 0.1 AEP, 0.01 AEP, July 2017, August 2017, May 2020, July 2024, and July 2025 hydrograph data are documented in this section.

For theoretical annual exceedance probability events, one precipitation hyetograph was applied for the entire watershed. For historical events, a grouping of gage locations used the Thiessen polygon method to implement recorded precipitation hyetographs across the watershed. See Figure M.2.1 for Stormwatch gage locations.

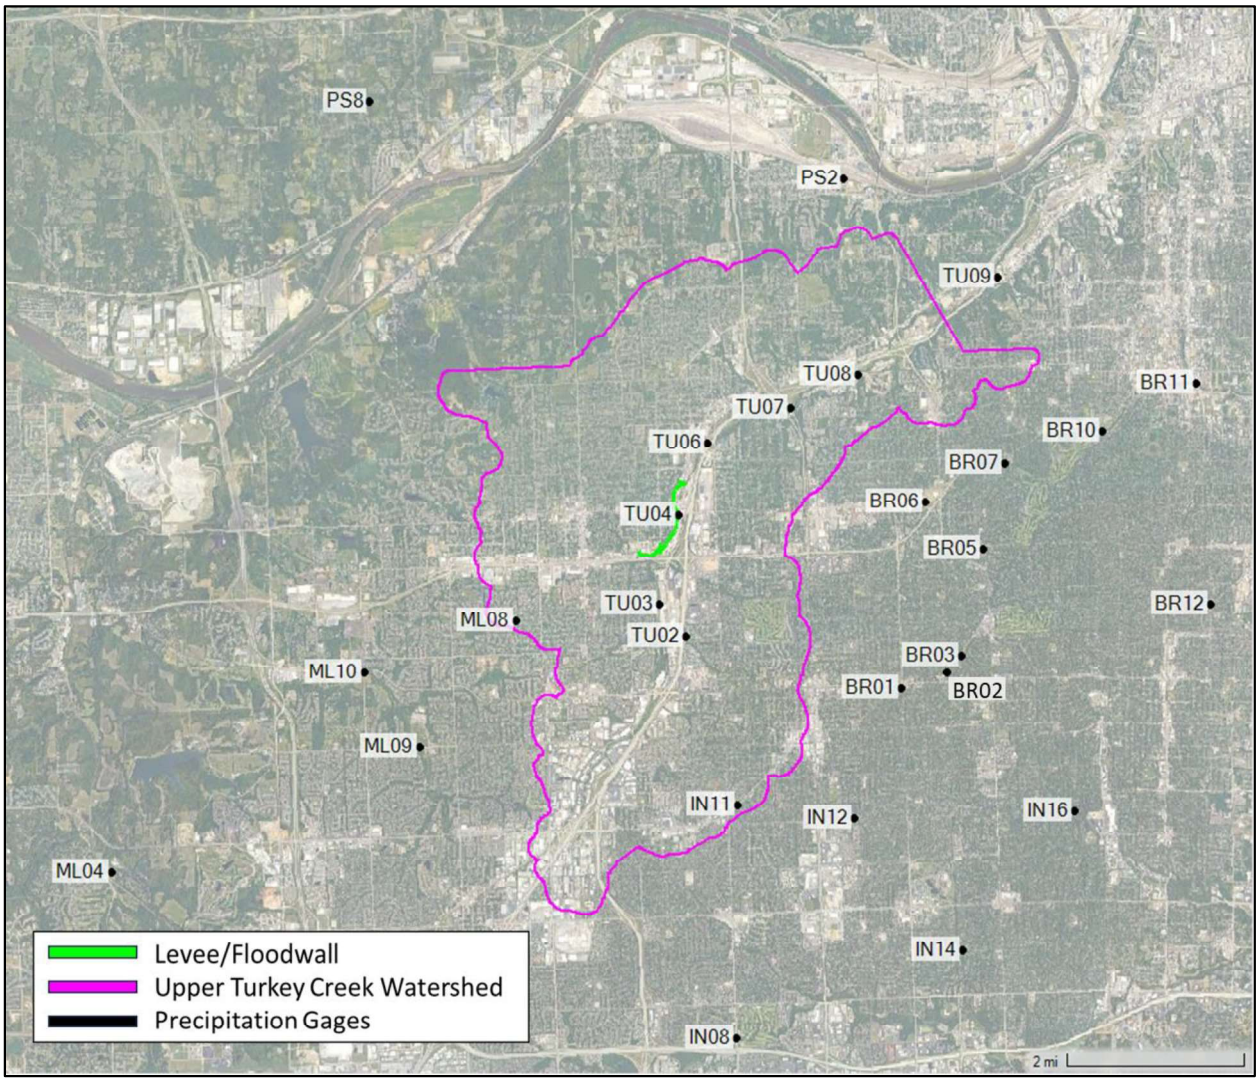

Figure M.2.1. Stormwatch Gage Locations.

M.2.1 THEORETICAL PRECIPITATION EVENTS

The theoretical precipitation events are 24-hour events, with a 5-minute time step. See Section 5.1.5 for more information.

Table M.2.1. Theoretical AEP Event Hyetograph Data.

APPENDIX M.3 – HEC RAS PIPE NETWORK INFORMATION

EXISTING CONDITIONS HEC RAS NODE ATTRIBUTE TABLE

EXISTING CONDITIONS HEC RAS CONDUIT ATTRIBUTE TABLE

PROPOSED CONDITIONS HEC RAS NODE ATTRIBUTE TABLE

PROPOSED CONDITIONS HEC RAS CONDUIT ATTRIBUTE TABLE

M INTERIOR DRAINAGE

M.3 HEC RAS PIPE NETWORK INFORMATION

The HEC RAS node and conduit attribute tables are included below for both existing conditions and proposed conditions.

Node coordinates are in the North Kansas State Plane projection. Node elevations (Elev) are in feet NAVD 88.

Existing nodes have no HEC-RAS pipe network side inlet attributes.

All conduits have zero upstream (US) and downstream (DS) offset. US Entrance, DS Exit, US Backflow, and DS Backflow coefficients are all set to 0.5. If DS Flap Gate equals Flap, then that conduit has a no negative flow flap gate, preventing water from Turkey Creek entering the leveed area through the pipe.

M INTERIOR DRAINAGE

M.3.1 EXISTING CONDITIONS HEC RAS NODE ATTRIBUTE TABLE

Table M.3.1. Existing Conditions Node Attribute Table

APPENDIX M.4 – DRAINAGE STRUCTURE INFORMATION

PROPOSED CONDITIONS DRAINAGE STRUCTURE DATA TABLE

M INTERIOR DRAINAGE

M.4 DRAINAGE STRUCTURE INFORMATION

M.4.1 PROPOSED CONDITIONS DRAINAGE STRUCTURE DATA TABLE

14 drainage structures are designed to go under or though the levee or floodwall line of protection. Coordinates are in the North Kansas State Plane projection. Landside (LS) and Riverside (RS) denote what side of the line of protection is being referenced.

Pipe lengths and slopes in this table reflect information from hydraulic modelling, not civil design. Hydraulic pipe lengths should be near the value provided by civil, slopes may vary due to differences in pipe length. These deviations are not expected to significantly impact results as pipe nodes work within the larger 2D cell structure.

Limitations in hydraulic modelling of pipe networks may also lead to some deviations from civil design values, specifically for the detention basin outlet inverts. These deviations are not expected to significantly impact results as the slope is maintained.

M INTERIOR DRAINAGE

Table M.4.1. Proposed Conditions Drainage Structures Data Table

Drainage Structure	Diameter (ft)	LS Invert (ft)	RS Invert (ft)	Length (ft)	Slope	LS X Coordinate	LS Y Coordinate	RS X Coordinate	RS Y Coordinate	Maximum Velocity (ft/s) for 0.1 AEP
